DR. BALLANTYNE contributed a paper on the diseases of infancy and antenatal conditions, in which he pointed out that there were many means of investigating antenatal states and of connecting them with diseases or malformations occurring in infancy. Prominent among these was examination of the placenta, membranes, and liquor amnii, which was in general greatly neglected. Bacteriological and histological examination of the foetal annexa were of the highest importance. Foetal variola and syphilis had long been recognised, and within recent years cases of antenatal measles, scarlet, typhoid, yellow fever, malaria, erysipelas, and influenza had been recorded. Recent researches had also thrown much light on the inheritance of tubercle. It was possible that pathogenic organisms might pass to the foetus through the liquor amnii, many abnormal conditions of the skin being connected with abnormalities of this fluid. The excess over or absence of the vernix caseosa and epitrichium in relation to subsequent diseases of the skin was also a point of great interest. Experiments had been made proving that by variously altering normal incubation conditions monstrosities could be produced in the embryo chick. Anomalies of all kinds in children were frequently associated with a history of alcoholism, syphilis, or tuberculosis in the parents. It seemed reasonable to conclude that poisons circulating in the blood of the pregnant woman or present in the ovum or spermatozoon might so influence the development of the embryo and foetus that malformations might be produced.

FRIDAY, AUGUST 2ND.

A DISCUSSION ON DOSES OF VARIOUS REMEDIES AT THE SEVERAL AGES.

I.—J. KINGSTON BARTON, M.R.C.P. Lond.

AN official *Pharmacopæia* can only lay down general rules for dosage in drugs, the doses given being those applicable to adults. The usual deduction for age answers safely when one is in doubt, or has had no experience. On the other hand, individual experience in the use of particular drugs, when properly recorded, may be of service to others.

I take it that if in this discussion it appears that many with experience have positive observations upon the doses of certain drugs that do not harmonise with ordinary ideas, then at a future time the Section can recommend an extended report; or, if thought fit, the experiences given to us to-day by those who have kindly promised to speak can be forwarded, if not too late, to the Committee sitting upon the new *Pharmacopæia* that is to be published.

Sir Alfred Garrod, quoting Gaubius, gives that children of 1 year and under should have one-twelfth of the adult dose. The adult is taken at 25 years, and he further gives half adult doses as appropriate for 14 years, two-thirds at 20 years, equal gradations being made between the various periods

named. I would say further that the dose given for 1 year should be divided by twelve for each month.

Children so rapidly pass at times from a slight state of illness into, perhaps, a most alarming condition, yet they equally, fortunately, very often quickly recover. Hence in administering drugs of any potency it is a good rule to give the medicine in frequent small doses, diminishing the dose as the symptoms improve, and leaving off the medicine directly the symptom has yielded. In this way harm is avoided.

A medicine of any marked power seems to do little harm whilst its potency is being used upon a definite symptom, its harmful tendencies being for the time almost suppressed, morphine in affections of the peritoneum being a good example of this. I have seen children in acute peritonitis bear adult doses without harm if watched in the manner mentioned. I would add that a diagnosis of the probable cause of the peritonitis should, if possible, be first made before giving such large doses.

That the drugs administered to children should be of excellent quality goes without saying, and if patients cannot afford to go to first-class chemists, rather than use inferior drugs the medical man had better depend on treating his patient by bed, milk, broth, and water, which will carry children safely through most diseases.

1. *Ammonii Acetatis Liquor*.—The ordinary dose is too large. In large doses it causes sickness and considerable depression (weak and nervous). This action makes it valuable in the treatment of pyrexia. By giving drugs at frequent intervals in small doses one gets much better results than by large doses at longer intervals. Adult dose 2 to 6 drachms; $\frac{1}{2}$ to 1 drachm for children is given as ordinary dose. By preference give 1 drachm to a child of 12; 5 minims for 1 year, and so on up to 12 years. This dose may be given each hour for six doses, then each two or three hours according to the febrile symptoms.

2. *Ammonii Carbonas*, although valuable is not tolerated well by children in the stomach, causing sickness easily. Dose 2 to 10 grains. For children of 1 year, $\frac{1}{4}$ grain; for children of 12 years, 2 grains. This drug is more useful during recovery from pneumonia or bronchitic affection than in any other condition in children.

3. *Ammonii Bromidum*.—Dose 2 to 20 grains. This drug is much more useful than bromide of potash, as being less depressing. Children bear it in big doses if epileptic from nervous causes. A child 1 year old can tolerate gr. v easily, six each four hours, but none of the bromides are good to persist with owing to nervous depression and tendency to bromide rash which they produce.

4. *Anethi Aqua* is very valuable in flatulence in infants. It is best given before breast feeding, or with the child's bottle; but the usual doses are taken well; \mathfrak{ss} to \mathfrak{ss} dose given for infants; half this, and diluted, is a better dose.

5. *Antipyrin* is only to be mentioned to be condemned. By reducing temperature as quickly as it undoubtedly can, it more often than not complicates diagnosis. When clinical thermometry first came in we were encouraged to study the natural rises and falls of temperature in all the specific diseases. Seeing that in cold sponging or ice baths we have the only reliable remedy for hyperpyrexia, it is far safer to use the other diaphoretics whilst watching the early stages of febrile attacks, so as not to mask the well-known early characteristic temperatures. The modern craze for the reduction of temperature, utterly ignoring every other point, has flooded the market with a series of dangerous antipyretics.

6. *Arenaria Liquor Sodii*, is perhaps the most useful and safe way of administering this drug to children, chiefly because the effect on requiring its use are generally the accompaniment of the acid diathesis, and hence it may be combined and taken with alkalies; \mathfrak{ss} to \mathfrak{ss} being for adults, one might be disposed to order more than would be borne well; a child of 12 years will bear \mathfrak{ss} in water three times a day very well; a child of 1 year old bears \mathfrak{ss} very well.

7. *Bala Confectio*.—Accepting the fresh-made confection, the usual preparation is unreliable; for chronic intestinal catarrh it is very valuable, \mathfrak{ss} to \mathfrak{ss} being sufficient for adults; it is chiefly useful to those from tropical climates.

8. *Belladonna Extractum of Tinctura*.—As this drug so often fails in its repute for curing enuresis or pertussis,

and as its full doses are so extremely unpleasant, excepting in small doses frequently repeated, it is wise not to employ it. The extract is apparently more potent than the tincture. The dry throat and the restless nights (semi-delirium) are the chief distressing symptoms.

9. *Boraci Glycerinum*.—This is a most valuable preparation. Sucked or painted freely in the mouth, it quickly cleanses the mouth of all aphthous affections, and in young children is the safest and simplest if not most efficacious remedy in diphtheria. The danger of ramming brushes down struggling infants' throats is great; detached membranes are likely to be pushed into the larynx or swallowed into the stomach or pushed up behind the palate, only to sow fresh areas of disease; whereas, if 10 to 60 drops, according to age, are sucked every hour or two a throat may be nearly quite clear in twenty-four hours. If it is used in this way in surgical cases, the raw surfaces of tonsils, etc., never become white or semi-diphtheritic looking as they are wont to do when on milk diet after throat operations. As it produces no bad signs internally, and as it is chiefly eliminated by the kidneys, further good may be done if the urinary secretions themselves are in any way contaminated. A child of 10 years can take \mathfrak{ss} glycerine boraci six or eight times in twenty-four hours without harm; a child of 6 months can take \mathfrak{ss} every two hours for several days without any harm.

10. *Bismuthi Carbonas*.—Most valuable in the diarrhoea of infants from all causes, but requires to be given in large doses, combined with or without opium, as may seem necessary; also, being palatable, it is easily administered. The dose for an adult is 5 to 20 gr.; infants of 6 months will take 5 gr. quite easily each three or four hours with no harmful effect.

11. *Calomelas*.—The adult dose $\frac{1}{2}$ gr. to 5 gr., excluding the consideration of syphilis. Other preparations of mercury are more useful where there is indication for a thorough clearing out of the intestinal tract. Where there is a thick-coated or furred tongue nothing can equal calomel. For children under 1 year, 1 gr.; 2 years, 2 gr.; under 7, 3 gr.; followed in four hours by a mild saline-magnesia citrate, may be suggested as suitable. The idea that calomel causes injury to the teeth can be absolutely contradicted, and yet it is constantly quoted as a cause of deterioration, which can really be traced to bad feeding, or to the bad health that called perhaps for the use of calomel. The occasional extreme faintness that is noticed after the administration of calomel may be due to some impurity in the drug. In commencing laryngeal catarrh with the harsh croupy cough, if given in large doses it cuts short the attack as nothing else can. The frequent administration of smaller doses of calomel for the liver or to bring colour to the stools is very useless and probably very harmful.

12. *Chloral Hydras*.—Adult dose, 5 gr. to 30 gr.; for 1 year $\frac{1}{2}$ gr. to 3 gr. is suggested. Its chief use in infants is for convulsions, which if due to any reflex cause can be controlled and stopped by steady administration of fairly large doses. Two grains each two hours for six doses were given in an infant eight weeks old without any ill effect. In asthma this drug is also very useful. Asthma being rare under 1 year, but not rare between 1 and 12 years, doses of 2 gr. to 5 gr. should be repeated each hour during the asthmatic fit, which is generally worse at night.

13. *Chloroformum*.—For surgical operations on very young children (under 7) it is certainly the most comfortable anæsthetic for the operator. Infants in arms do not seem to suffer so readily from chloroform sickness. There is less hæmorrhage as a rule than with ether administration. In children under 3 who have any signs of rickets, chloroform is apt to bring on very unpleasant respiratory difficulties. Children with asthma do not bear chloroform well (differing in this respect from adults). The American plan of administering chloroform for convulsions is not so simple as the administration of large doses of chloral internally.

14. *Camphora Aqua* is very objectionable to children in taste; it is best administered diluted when there is any special reason for its being given.

15. *Ferrum Reductum*.—The adult dose is 1 to 5 gr.; children $\frac{1}{2}$ to $\frac{1}{2}$ gr. However, infants under 1 year can easily take 2 gr.

three times a day. If there is any constipation $\frac{1}{2}$ to 2 gr. of powdered liquorice root can be added to the iron powder with advantage, and sugar of milk may be added as a vehicle. In true anemic states, this preparation reddens the blood sooner than any other. It is extremely useful in the anemias of hand-fed and rickety children. It is less likely to disagree than any other form of iron, and has less ill effects. The teeth may be blackened but not in any way spoilt, as they may be when t. ferri perchlor. in acid solution is given.

15. *Ferri Iodidi Syrupus* is a most unpalatable mixture for children, and also more often than not seems to disagree with the function of the liver and stomach; it is better tolerated in very small doses. For children who can swallow pills; pot ferri iodidi is much more easy of administration.

17. *Hyd. c. Cret.*—In gastric and intestinal irritation, when the alternative action of mercury is desired. This remedy is most valuable. Small doses repeated at intervals till the stools are altered, is perhaps the most effective way of giving this drug. For children under 2 years $\frac{1}{2}$ of a grain every four hours until 1 grain has been taken is a suitable dose. Children bear the drug well, and it is not likely to be followed by the faint condition that is sometimes induced after calomel. Between 2 and 12 years, 3 to 5 grains may be given as a single dose when required.

18. *Ipecacuanha Vinum* is very apt after a few doses to produce nausea, even in doses of 5 minims. On the other hand, \mathfrak{zj} very often fails to produce vomiting. The adult dose is 5 to 40 minims; as an expectorant, 3 to 6 drachms, hence for 1 year old half a drachm should be drastic. If larger doses are given there is much prostration and some traces of irritation of intestines. Dose for infants under 1 year, 1 to 3 minims; 1 to 12 years, 2 to 10 minims, or $\frac{1}{2}$ a minim a year. For emesis $\frac{1}{2}$ to 13 minims for children under 1 year, followed by frequent teaspoonfuls of warm water, and then tickling the throat gives the best results. Especially night and morning for loaded bronchial tubes.

19. *Ipecacuanha et Morphina Trochisci.*—Extremely useful in spasmodic irritable cough after acute stages have passed off, especially if the cough is not accompanied by much phlegm. Children under 2 rarely require opiates for cough. For a child from 2 to 12 years old with irritable cough, worse at night and keeping the child awake, $\frac{1}{2}$ to $\frac{1}{4}$ of a lozenge each fifteen minutes will, after two or three doses, give much relief, and the small dose produces but little ill-effect upon digestion.

20. *Opium.*—Excepting in peritoneal or enteric affections it is important to be very careful in the administration of opium or its compounds. The congestion of the pulmonary circulation, as well as that of the cerebrum, being with constipation its chief baneful effects. In peritonitis or troubles outside the bowel, but requiring quiet of the neighbouring parts, hypodermic injections of morphine are undoubtedly most satisfactory, and the doses must be given at regular intervals to prevent the morphine sickness. In tuberculous peritonitis a child of 5 will bear $\frac{1}{2}$ grain of morphine each three or four hours, and, although delaying the action of bowels, it does not cause the hard lumps of feces that collect when opium is administered by the mouth.

21. *Opii Liquidum Ext.* is the best preparation for internal administration. Combined with bismuth it is the most reliable means of controlling violent diarrhoea in children. The old dictum, one drop for each year, is a very fair division for all conditions which require decided dose of opium, and $\frac{1}{2}$ for each month under 1 year. For controlling cough the most minute doses are sufficient, even doses of t. camph. co. being sufficient. If excretions in the bowel or lung which ought to be expelled by evacuation or by expectoration are retained by the holding effect of opium, then serious harm is done. A minute dose of morphine more quickly controls the sickness of morphine than anything else. Tea, coffee, caffeine, or an effervescent saline best relieves the sickness of opium itself.

22. *Potassi Chloras.*—In all throat and mouth affections this drug, with potassi citras, given each hour for numerous doses gives quick relief. The effect is depressing on the heart, chiefly in slowing the heart's action together with some tension of arteries. A child of 1 year can take 1 grain per hour for twelve hours and then every two or three hours. A severe tonsillitis will be nearly gone in forty-eight hours

with this treatment. The potas. cit. is double the dose of potassium chlorate. If the drug is required for a longer time, liq. strychninae can be added with good effect.

23. *Potassi Bromidum* is the same as ammonii bromidi; if continued long it increases hysteria.

24. *Senna Confectio* is the most certain of laxatives for continued constipation, only it must be given regularly, the actual dose being gauged by test, $\frac{1}{2}$ to \mathfrak{zj} will suit for 1 year to 5 years.

25. *Senna Syrupus* is extremely uncertain; many children take the adult dose without effect.

26. *Sulphuris Confectio* is most unreliable in its effect.

27. *Sulphur Precipitatum vel Sublimatum* is the best way of administering this drug when required. A child of 1 year requires gr. 5; 6 months, gr. \mathfrak{ij} ; 12 years, gr. xxx. It is most useful in boils, lichen, or urticaria; in fact in all skin affections of childhood.

28. *Sodii Phosphas* is practically useless, its effect is so uncertain.

29. *Sinapis Cataplasma*, although so useful, is very difficult to apply to children. By diluting with a full equal part of wheat flour, the intensity of rubefacient action is diminished and made bearable.

II.—JOHN H. MORGAN, F.R.C.S.,

President of the Section.

THE PRESIDENT congratulated himself that it did not fall to his lot to have to administer many drugs. With regard to anaesthetics, he infinitely preferred ether for even the youngest children, whenever the nature of the operation made it possible to give it.

III.—ARTHUR FOXWELL, M.D.,

Physician, Queen's Hospital, Birmingham.

DR. FOXWELL said that, speaking generally, the doses given to children were too small; calomel, belladonna, and arsenic, for example, could, he believed, be given in absolutely larger doses than to adults. He had frequently given 1-grain doses of calomel every few hours for a week without observing any poisonous effect. Indeed this was his routine treatment for acute laryngitis, membranous and non-membranous. Liquor sodii arsenicalis was another drug which children bear remarkably well; the dose could often be quickly raised till it reached 10 or 15 minims, given thrice daily without producing any ill effect. Belladonna was often successful in enuresis when given in a simple large dose every night, say 20 to 30 minims in a child of 10. He had known this to succeed when doses of 10 minims given thrice daily have been without result.

IV.—DAWSON WILLIAMS, M.D., F.R.O.P.,

Physician, East London Hospital for Children.

DR. DAWSON WILLIAMS agreed that doses given to children were often too small. He was disposed altogether to doubt the age theory of dosage. Certainly in those cases in which it was necessary to give antiseptics large doses only were of any service. With regard to mercury, he did not believe there was any danger of giving too much. If syphilitic children did not improve upon the drug it was a sign they were not having enough. He gave it in large doses, and had never seen an infant salivated. He believed in large doses of belladonna also, and had found it of the greatest value in whooping-cough. With regard to what they should ask the Pharmacopoeia Committee of the General Medical Council to do, he thought they might, perhaps, ask them to give a table of doses which might protect them in a sense from accidents. But they could only ask for an empirical table, and not a weight-for-age table.

V.—D. J. LEECH, M.D., F.R.C.P.,

Senior Physician, Manchester Royal Infirmary.

DR. LEECH said that in giving a table of dosage for children, such as had been suggested, great difficulties would arise. In the *Pharmacopoeia* the doses given were meant to be average doses, and in any table which could be drawn out relating to doses for children only the average for various

ages could be given. The dosage for children might be indicated by physiological considerations or by certain arithmetical calculations, but could only be determined by experience. The tissues which are most recently developed are always most readily affected by physically active agents; hence it is, perhaps, that opium has such a powerful effect on the brain of young children, and in the case of new drugs the sensitiveness of the tissues must be borne in mind when the dose is considered. If any adult took antimony and ipecacuanha experimentally and a full dose, they would be able to contrast easily the difference between the long-abiding depression and nausea caused by the former, and the slight effect the latter left when the nausea had passed off. Children must feel the same as adults, though in illness they could not express this. Dr. Leech expressed surprise at the statement of the reader of the paper concerning the value of belladonna and the effect of this drug in large doses in the enuresis of children. Children of 7 years old will often take doses of Green's belladonna, gradually raised to 30 drops, three times daily without showing signs of any discomfort. No grave evils had ever, as far as he knew, followed from the heroic use of belladonna in enuresis or any other ailment. Quinine was another remedy which might be given in large doses without any fear of evil. A child of 18 months suffering from severe whooping-cough would derive only benefit from 3- or 4-grain doses of quinine three times daily. The calculation of Glenk, Cauling, and Young as to the relation in proportion between the doses proper for various ages and the average dose for an adult could not be relied on as a safe guide for dosage in children, though doubtless they gave an idea as to the dose which might be suitable for any particular age, such calculations required to be modified by physiological views and experience. Generally speaking, it may be said that substances which depress the nervous system powerfully, directly or indirectly, cannot be given to children in large doses without danger. Hence it is necessary to be cautious in the administration of opium, brisk purgatives, antimony and apomorphine in doses which approach in any way near that given to adults. Antimony is a drug capable of doing much harm in such doses. The evils of antipyrin have been overdrawn. Four gr. or 5, to a child of 5 or 6, repeated, if necessary, in an hour, would often produce most marked benefit in cases of catarrh with high fever, in which slight twitching of the muscles pointed to the possibility of an impending convulsive attack, and in many other conditions also, but he would not advise antipyrin as a continuous remedy. The marked action of moderate doses in depressing the circulation, both in children and adults, had been only suspected but never proved. Bromide of potassium, too, had been unduly blamed for causing depression. The idea that the potash had the smallest effect in depressing the nervous or muscular system in such doses as 2 to 10 gr. was a myth founded on an erroneous inference from experimental pharmacology. Potash in enormous doses will depress all the tissues, but in medicinal doses it is free from such effects, both in children and adults. Concerning chlorate of potash in full doses, it was well to remember that under some conditions, but little understood, it powerfully influenced the blood corpuscles, destroying them and leading to hæmaturia. If acetate of ammonia does produce sickness or depression, it does so by a slight irritant action which all strong salines may cause in the stomachs of children.

VI.—NESTOR TIRARD, M.D., F.R.C.P.,

Professor of Materia Medica and Therapeutics at King's College.

Dr. Tirard pointed out that in adults the doses of remedies employed must necessarily be regulated by the nature of the drug employed, by the nature of the disease for which it was employed, the condition of the patient and the purpose of employment. In dealing with adults it was often difficult to find practitioners agreed upon the dose to be employed. He remarked that it was common to meet with practitioners who thought the *Pharmacopœia* doses too large, while others thought them too small. Where so much variance of opinion obtained with regard to adults, was it possible to formulate general rules for the dosage of children? While admitting the great differences in effects upon children and adults relating to such drugs as mercury, opium, belladonna, and

many others, he thought from his own experience that it was absolutely futile to attempt to draw up tables indicating the doses for varying ages, when practically the dose invariably had to be determined by the condition of the child and the nature of the disease as well as by the age. He believed the best guide to be experience.

MR. J. KINGSTON BARTON'S REPLY.

Mr. KINGSTON BARTON, in replying, proposed the following resolution:

That this Section should petition the Council that a list of maximum and minimum doses should be added to the *British Pharmacopœia*, especially with regard to children under two years old.

Dr. LEECH pointed out that the existing doses given were average, and not maximum and minimum doses.

After some further discussion Dr. DAWSON WILLIAMS proposed the following resolution, as suitable in form for conveying the views of the Section to the General Medical Council:

That this Section thinks it desirable that in the new edition of the *British Pharmacopœia* the maximum doses of powerful drugs suitable for children at various ages should be indicated.

Mr. J. KINGSTON BARTON seconded the resolution in this form, and it was put to the meeting and carried.

ON THE VALUE OF TREPHINING IN TUBEROULOUS MENINGITIS.

By EDMUND CAUTLEY, M.D. Cantab.,

Physician, Belgrave Hospital for Children.

THE author commenced by giving an abstract of a case of acute meningitis under his care. The patient was operated on by trephining with temporary relief but, dying shortly after, the *post-mortem* examination revealed that the meningitic affection was part of an acute general tuberculosis. Two cases of acute meningitis in children, who recovered after operative treatment, are also referred to. One of these was under the care of Dr. W. W. Ord and Mr. Waterhouse, and the other under the care of Dr. C. A. Greaves.

To contrast with these, reference is made to a case of acute basal meningitis in a boy in whom coma supervened and lasted for a week, and yet the patient recovered without operative interference; and to a case of pseudo-meningitis occurring in a child as a sequel of influenza.

The theory, on which trephining for meningitis is based, is that the coma and death of the patient are dependent upon the pressure consequent on effusion of fluid. On the other hand many cases occur in which no evidence of effusion, sufficient to cause the symptoms and result, is found on *post-mortem* examination. The softening of the brain tissue, so commonly present, is not due to compression by effused fluid, but is due to the interference with the blood supply.

The coma is dependent upon the amount of softening, and is exaggerated by the pressure in cases where there is much effusion. The onset of coma is of very serious import, but that it may be occasionally recovered from is evident from the result in one of the cases referred to. At present we have a certain amount of evidence to show that in some cases the degree of coma is lessened by the relief of intracranial pressure.

It is probable that the amount of effusion in a case of meningitis depends partly upon the cause of the disease and partly on the regions affected.

If operative interference is of value, it is only so in cases of considerable effusion. Large effusions are more common in cases of acute simple meningitis than in those due to tuberculous infection. Cases of tuberculous meningitis sometimes recover without operative interference. As a rule, such cases generally lack absolute proof that they are tuberculous in origin. Operative interference should only be undertaken when there is evidence of intracranial pressure. The difficulties of obtaining such evidence in cases of tuberculous meningitis are very great, and many of the symptoms in the late stages are not those usually associated with cerebral compression. It is advisable to operate before the supervention of coma, during the stage of irritation. Operation at such a time must only be undertaken after the most careful consideration, on account of the great liability to error in

diagnosis at this stage of the complaint. Thus symptoms of basal meningitis may occur in cases of acute croupous pneumonia and other febrile disorders, in middle ear disease apart from any actual extension of the inflammation to the meninges, in cases of basal irritation following influenza, and in cases of reflex irritation consequent on the presence of worms in the alimentary canal.

In conclusion, it is pointed out, first, that tuberculous meningitis is almost always part of an acute general tuberculous infection, generally secondary to breaking down caseous glands at the roots of the lungs or in the mesentery, and that operative treatment in such cases is unlikely to result in more than a temporary amelioration of the symptoms.

Secondly, that in view of the fatal issue of these cases, and the fact that cases operated on, and supposed to be tuberculous, have recovered, it is justifiable to operate in those cases which present signs of cerebral compression.

Thirdly, that the operation produces temporary improvement, and is more likely to result in a successful issue than the expectant treatment generally adopted.

Mr. Power congratulated Dr. Cantley upon his instructive paper. He alluded to the animus often displayed against the operation of tuberculous meningitis with effusion. He pointed out that it was necessary to select cases of basal meningitis with great care as only a few were fit for operation. No case of infective meningitis should be trephined—at any rate early—for they often recovered. Those cases of tuberculous meningitis should alone be operated upon when the onset was acute, and there were no symptoms of general infection. The diagnosis of the disease was easy by means of Quinke's puncture of the vertebral canal between the laminae of the lumbar vertebrae. Mr. Power said that he had trephined several cases of tuberculous basal meningitis during the last year. He had unfortunately never succeeded in saving life, but the result of his experience was that life was prolonged for three to ten days in a child who was apparently moribund at the time of the operation. The most remarkable result of the operation was a permanent and very marked depression of temperature. This delirium was a result of lowering the intracranial pressure. On one or two occasions, whilst the lateral ventricles were being drained, the flow of cerebro-spinal fluid became arrested, and the temperature again rose, falling as soon as the flow was re-established. No harm was done to the cerebral substance from the adoption of a horsehair drainage, as he had recently examined a brain in which the track of a bundle of horsehair which had been in position for several days, and had been removed ten days before death, could not be detected at a carefully conducted necropsy after the brain had been hardened in Ford's solution. The cerebro-spinal fluid was not very prone to support pyogenic organisms, and it was therefore easy to keep the intracranial cavity aseptic. Mr. Power had trephined and drained the subarachnoid space in some cases, whilst in others he had trephined and drained one or other lateral ventricle. The foramen of Majendie was usually patent. A bundle of twelve to twenty horsehairs was preferable to tubes for the purposes of effecting drainage, and it was better to bring the bundle through a hole cut in the centre of the horsehair skin flap, than to bend it so as to bring it out between the edges of the flap.

Mr. HERBERT WATERHOUSE said he was very glad to take part in this discussion, as the successful case upon which he operated in October, 1893, had, he thought, encouraged operations on cases of tuberculous meningitis. Whilst he felt sure that in the majority of cases tuberculous meningitis must be fatal, still he held that in few cases the operation of trephining and draining of the subarachnoid space might be expected to give a favourable result. He thought that when a child with tuberculous meningitis had symptoms of cerebral compression and is becoming comatose, it is not only justifiable but necessary to trephine and drain to ward off death by cerebral compression. There was little doubt that occasionally tuberculous meningitis recovered without operation. This view was supported by the not infrequent presence of calcified tubercles in the meninges months or years after an attack of apparent tuberculous meningitis. It might be readily understood that the relief of pressure by withdrawal of fluid in meningitis could not be otherwise

than salutary. In these cases the foramen of Majendie was always patent. Drainage must be continued for several days, puncture alone was insufficient. A noticeable and immediate improvement, even if only temporary, always resulted on removal of the fluid. It is essential to operate before the stage of coma had been reached, that is, before damage has been done to the cerebral substance. It was, of course, useless to operate in cases of general tuberculosis. With regard to operation the large collection of cerebro-spinal fluid between the central lobe of the cerebellum and roof of the medulla was readily reached and drained by the method he adopted in his first case. Successful cases must be few and far between. He only urged operation in cases where there were signs of cerebral compression.

Dr. CAUTLEY said in reply he had included non-tuberculous cases because the diagnosis was often difficult. Optic neuritis might occur without intercranial pressure. Small calcified tubercles might be found in cases in which there had been no true meningitis.

OSTEOCLASIS.

By NICHOLAS GRATTAN, F.R.C.S.I.,

[Senior Surgeon, Cork Hospital for Diseases of Women and Children.]

MR. GRATTAN showed a powerful steel apparatus for osteoclasia. He had operated by means of it in 220 cases. He used it not only for operating on the femur in knock-knee, but also for fracturing curved bones in the legs, and for correcting many forms of club-foot and flat foot. He had had one case of tetanus which had recovered in a week, and one case of delayed union following its use, otherwise his results were exceedingly good. It was important not to press on any large artery or nerve. Skin wounds were easily avoided by taking care that the fold of skin beneath the instrument was kept very loose.

HERNIA OF THE OVARY IN AN INFANT WITH TORSION OF THE PEDICLE.

By C. B. LOCKWOOD, F.R.C.S.,

Assistant Surgeon, St. Bartholomew's Hospital.

THE child was brought to the hospital with an oval swelling about 3 inches long in the right inguinal region. Having the local characters of an inflamed strangulated inguinal hernia. An incision along the course of the inguinal canal exposed a bluish red cyst with walls $\frac{1}{2}$ inch thick. When this was opened the ovary, full of blood, and the deeply engorged fimbriated end of the Fallopian tube came into view. About $\frac{1}{2}$ inch from the internal abdominal ring the pedicle had made a half turn upon itself, thus causing the vascular engorgement; when the ovary was pulled out of the sac the half turn disappeared. The pedicle was transfixed and tied, the ovary and tube were removed, the sac was excised, the stump fixed beneath the internal oblique and transversalis, and the inguinal canal sewn up; recovery was uninterrupted. It seemed, as a rule, that as the broad ligament with its contents turned the corner of the internal abdominal ring to get into the inguinal canal, the position of the ovary was reversed. It kept its position with regard to the Fallopian tube, but became anterior instead of posterior. In the present instance the ovary was highest, having ascended in front of the Fallopian tube. The latter seemed to have fallen behind the ovary so as to be hidden from view except its fimbriated end. There was nothing to show how this displacement had occurred, but the end of the broad ligament was quite loose within the hernial sac, so that considerable mobility must have been allowed.

AFTER-HISTORY OF TWO CASES OF CRANIECTOMY.

By TELFORD SMITH, M.D.,

Medical Superintendent, Royal Albert Asylum, Lancaster.

AFTER reviewing the various opinions held on the question of brain development in relation to the growth of the cranial cavity, Dr. Telford Smith said though results had not justified the operation, the hopeless outlook in these cases had certainly justified the experiment. The two cases cited

were very favourable ones for the experiment, and seemed fair instances from which to form a conclusion as to its advisability. The first was a well-marked case of microcephalic idiocy, otherwise healthy and well developed, and with apparently nothing but the microcephaly to account for his mental deficiency. He had in five operations an ample amount of the bony brain case removed, and had since had every advantage of special training and education. He had since the operation ceased to knock his head as he had previously done; but though this was a distinct improvement in his condition, it hardly seemed an adequate result for the risk run. His mental state remained very much as before, and any slight improvement there was would probably have been obtained by educational methods alone.

The second patient was a good test case as to the advisability of the operation in congenital idiocy, being a profound instance of this condition. In this boy it was impossible to see any mental improvement or sign of brain development, and he thought in a similar case the operation would now rightly be considered unjustifiable.

Dr. SHUTTLEWORTH confirmed the account given by Dr. Telford Smith of the craniectomised patients, having formerly had them under his observation when medical superintendent of the Royal Albert Asylum. He mentioned also another case, the child of a medical man, in which craniectomy had been done for the relief of microcephalus with but very slight mental improvement, and deterioration of his general health. There seemed to be no rationale for such an operation in the majority of cases of microcephalus, which as a rule depended on prenatal defect of brain development, not upon abnormal covering of bone. At any rate, cases of premature synostosis causing microcephalus were very exceptional, and it was only on clear evidence of absence of fontanelles that surgical treatment was appropriate. Special training was of much more service in promoting mental improvement.

A PROTEST AGAINST THE USE OF THE TERM "CONSUMPTIVE BOWELS" IN THE WASTING DISEASES OF INFANTS.

By J. WALTER CARR, M.D.,

Assistant Physician, Royal Free Hospital.

THE term "consumptive bowels" is still in common use, both amongst the laity and medical men, in marasmic conditions of young children. It may be supposed to cover one or more of three conditions—tuberculous peritonitis, tuberculous enteritis, and cessation of the mesenteric glands.

Of these, tuberculous peritonitis is almost unknown under two years: out of 257 consecutive necropsies on children under that age there was only one example of the disease (in a child of 1½ year). Tuberculous disease of the intestines and mesenteric glands is far more common, but in nearly every case is slight and recent, and not likely to give rise to any symptoms, being either merely a part of a general tuberculosis or else occurring in cases in which mischief in the lungs is evidently the primary and more important lesion, both pathologically and clinically. But of the 257 necropsies mentioned (including 53 in which tuberculous mischief was found) in only 3 were there intestinal ulcers of large size or old standing, and in only 1 did it seem at all likely that the tuberculous process had started in the bowel; in two or three other cases in which children had died from entirely different causes early cessation was found in the mesenteric glands, but in such a stage as to have been entirely incapable of diagnosis during life.

On the other hand, in practically all cases in which children die from what is commonly called marasmus, associated usually with more or less diarrhoea and vomiting, no tuberculous lesion is found on *post-mortem* examination, or at any rate none sufficient to account for the symptoms during life, still less to cause death.

Such conditions of marasmus are due in the immense majority of cases to improper feeding, and are not attended with any gross lesion whatsoever.

The improper use of the term "consumptive bowels," is calculated to lead to serious laxity in treatment, especially amongst the lower classes, the child's recovery being regarded as quite hopeless; whereas most conditions of marasmus, if dealt with sufficiently early, are perfectly curable, if only proper lines of treatment—mainly dietetic—are adopted.

From every point of view therefore the term "consumptive bowels" ought not to be used, except in very rare cases, in connection with children under 2 years of age; as, if the wasting be due to tuberculous disease, there will almost certainly be well marked signs of pulmonary or disseminated lesions to account for it, and, if there be no distinct evidence of tubercle, and no other obvious cause, such as congenital heart disease or prematurity, the wasting is almost certainly due to improper feeding, aided perhaps by general unhygienic conditions.

A MILK STERILISER.

By C. W. CATHCART, M.B., F.R.C.S.,

Assistant Surgeon, Royal Infirmary, Edinburgh.

MR. CATHCART showed a simple form of milk steriliser for infant feeding. After laying great stress on the importance of properly sterilising the milk given to children in order to avoid the various diseases that might be communicated through this channel, he pointed out that the plan of boiling milk had many disadvantages, and was in many houses an impossibility, while the sterilisers already in use are somewhat cumbersome and too expensive to be within the reach of all. A sterilising vessel should have a capacity of 50 to 60 ounces. It must be easily heated in a convenient-sized pot; it must provide some mechanism for stirring the mixture, so as to prevent the cream coming to the top. The quantity required for each meal should be capable of being withdrawn without risk of contamination. Every part must be easily cleaned, and it must be so simple that any unskilled person could use it, and so cheap as to be within the reach of all. The simple apparatus described met all of these requirements, and he had found it in his own experience altogether useful and reliable.

REVIEWS.

THE RECENT EVOLUTION OF SURGERY. By A. PRARON GOULD, M.S., F.R.C.S. London: Kegan Paul. 1895. (12mo, pp. 63.)

MR. PRARON GOULD has done well to publish in this form his oration to the Medical Society. He tells the triumph of modern surgery with true love of his art, and he gives a new turn to the story, taking for his subject not the technical aspect of surgery, but the aim and ideal and principles of the good surgeon. His discourse is not of new instruments and methods, but of new duties and responsibilities. His address is indeed the natural expression of a good surgeon, proud of his art, astonished at the speed of its advancement, and oppressed by the demands that it makes on him; but he is wrong in speaking of the "recent evolution of surgery." There is no such thing as recent evolution, any more than recent space or recent gravitation. And he does not do justice to the great surgeons who lived in the days before antiseptic surgery. He would apply to Lister that fine high-flying saying of Pope's:

Nature and Nature's works lay hid in night—
God said, "Let Newton be," and there was light.

But not even to honour Lister should he speak lightly of those who preceded him, the "fortes" who "transierunt Agamemnonem." He thinks that their "brilliance" was a poor sort of thing that we have done well to leave behind us, but it is really a lost art, and a little more of it would not be a bad thing in these days when everybody operates, whether Nature meant him to do so or not. Nor did our forefathers sacrifice a limb by amputation without regret and abhorrence as deep and strong as those which move the surgeon of to-day; and in general their aims and ideals were more like ours than Mr.

Could implies: when we consider the stupendous difficulties of their task we can only admire their work.

Nevertheless this oration is full of thoughts that deserve to be remembered. He looks at his art from a lofty standpoint, and yet it is plain that what he preaches he also practises, and that the conventional oration demanded by the habits of a venerable Society has been this time illuminated by true enthusiasm.

TRAITÉ PRATIQUE DES MALADIES DU SYSTÈME NERVEUX.

[A Practical Treatise on Diseases of the Nervous System.]

Par J. GRASSET et O. RAUZIER. 4me. Édn., 2 vols. Paris: G. Masson. 1894. (Imp. 8vo. Vol. i, pp. 900; Vol. ii, pp. 1,092. 33 plates, 122 figures.)

LEHRBUCH DER NERVENKRANKHEITEN FÜR ARZTE UND STUDIRENDE. [Handbook of Nervous Diseases for Practitioners and Students.] Von Professor Dr. H. OPPENHEIM. Berlin: S. Karger. London: Williams and Norgate. 1894. (Roy. 8vo, pp. 870, 230 fig. M. 22.)

We need, perhaps, do little more than announce to our readers the appearance of the fourth and enlarged edition of Professor Grasset's well-known work, which has had the reputation at the hands of the medical profession which it well deserves.

The author, finding the task of keeping pace with the rapid strides of neurology during the last eight years a severe one has called to his assistance the able hand of Professor RAUZIER, of Montpellier; and the collaboration has resulted in the production of a work which would have been monumental were any work a monument in these changing times. But we fear that no literary or scientific merit will save a book from oblivion nowadays, so fast is the pace. Happily this consideration does not discourage men like these authors from putting forth their best.

In the present edition nine most important chapters are entirely new, others are so far rewritten as to be practically new, and others again are brought up to date by liberal additions. Many new illustrations have been added, some original others borrowed from acknowledged sources.

To review this work, which perhaps may almost be called a new one, is far beyond our opportunities in this place, but we may make a special reference to certain sections which have attracted our attention, either on account of their able handling or of the freshness of the contents. Among these are the chapters on Aphasia, Jacksonian Epilepsy, Thrombosis of the Sinuses, Chronic Chorea, and Pseudo-bulbar Palsies.

Besides these special chapters there are a number of sections taking a wide view of this or that aspect of general pathology or nosology, which kind of stimulating survey is always well done by our neighbours. In a word, the work is as readable as it is complete, and the excellent illustrations are very helpful. The admirable system, bright style, and clever exposition of the best French books are conspicuous in this, and a young reader could not have a more attractive introduction to the difficult and abstruse subject of which it treats.

On their first page the authors pay a heartfelt tribute to the memory of Charcot, who inspired their earliest efforts in this field of science. English authors, save in a few important places, do not seem to receive all the credit they deserve, but as there is no index of citations it is not easy to be sure of this.

The work of Professor OPPENHEIM is of a very different character. The very diffuseness of Professor Grasset's work makes it easy to read. Professor Oppenheim's has the opposite virtue of concentration. There are no coloured plates, but the cuts in the text are many—some excellent, others less admirable. Still the more important are, on the whole, the best. The masterly manner in which the author has contrived to pack every fact of importance into his fewer pages is really wonderful. We have tested this repeatedly by looking up new points, and have invariably found that which we searched for. Moreover, condensed as is Professor Oppenheim's style, yet it is not crabbed and involved as is the case with too many of his countrymen. It is not the

purpose of this volume to dilate upon the whole subject of nervous diseases as is done in the larger work of which we have previously spoken: it is less discursive, less chatty, but as a portable handbook of sound learning for ward use and the like, it is perhaps the best which can be recommended to the student of to-day.

THE OPIUM HABIT IN THE EAST: a Study of the Evidence given to the Royal Commission on Opium, 1893-94. By JOSHUA ROWNTREE. London: P. S. King and Son. 1895. (Demy 8vo, pp. 108.)

MR. JOSHUA ROWNTREE appears to have procured an early copy of the five volumes containing the testimony of 600 persons, in reply to 28,000 questions, elicited by the Opium Commission. In anticipation of the Commissioners' report, he set himself to analyse the mass of evidence presented in "2,000 pages of double columns of close print" from the anti-opium point of view. To handle such a mass of evidence and extract the truth out of it is no light task; and it would appear to be proper and becoming to postpone a study of the evidence until the judges who had heard and weighed it had delivered their decision; "but the past history of Royal Commissions does not warrant the placing of any high sanction on the conclusions they finally express." Therefore it is well to educate the public mind in advance. A proceeding of this sort in a judicial case would incur that terrible thing—contempt of court; but Royal Commissioners are evidently fair game.

The whole thing, according to Mr. Rowntree, has been mismanaged. The scope of the inquiry was, through Mr. Gladstone's mischievous intervention, unnecessarily widened. The British Parliament had pronounced the opium cultivation and traffic undertaken or permitted by the Government of India to be "morally indefensible"; and the only points remaining to be decided were, how the revenue hitherto derived from opium was to be made good, and what compensation for its loss was requisite. Instead of that, the Commissioners were actually instructed to inquire whether and to what extent the consumption of opium is prejudicial to health and morals, and whether the people of India wish its cultivation and sale to be restricted or suppressed. The constitution of the Commission was faulty; it was stuffed and staffed by Indian officials and led by the nose throughout by the interested Indian Government. The right witnesses were not brought forward; some members had the audacity to cross-examine an official who had indited a strong report against opium; and the police actually shadowed "our Mr. Wilson," who took a little trip into the district of Gya in order to obtain some really sound unbiassed evidence on his own account. Nevertheless it is possible to extract some gems of truth from the unfathomed depths of tainted testimony offered in these portly volumes, and Mr. Rowntree discovers, to his own satisfaction, that two Ministers of the Crown have committed "grave errors of language" in asserting that the policy of the Indian Government has been to diminish the cultivation of the poppy in India, and that China may refuse Indian opium if she does not want it; that the Indian peasant is compelled to cultivate opium against his will and interest; that the system of putting up licences for the sale of opium to public auction creates a class strongly interested in maintaining and extending its consumption; that the opium habit is in many districts and towns of India "deeply rooted and widely spread, and is the accompaniment of vice and demoralisation"; that the alleged beneficial effects of this habit as a prophylactic against malaria and an assuager of pain, fatigue, and misery are problematical; and that "the evil effects of the habit are both great and unquestioned"; it is only maintained in India at the price of a ceaseless toll of wrecked and shrunken lives at one end of the human scale and of infants sacrificed at the other, a toll of vast numbers of suicides and of nameless debauchery." The remedy is suppression—deprivation of liberty imposed by the few on the many otherwise than at the instance and request of the latter. Whether a policy of this sort is likely to make for self-restraint and virtue admits of question, and we doubt much that even the partial "study" presented in these pages justifies it.

LEÇONS CLINIQUES SUR LES MALADIES DES VOIES URINAIRES
PROFESSÉES À L'HÔPITAL NECKER. [Clinical Lectures on
 the Diseases of the Urinary Organs delivered at the Necker
 Hospital.] Par J. C. FÉLIX GUYON. Troisième Edition.
 Revue et Augmentée. Avec Figures et Planches Inter-
 calées dans le Texte. Tome I. Paris: J. B. Baillière et
 Fils. 1894. (Roy. 8vo, pp. 670, 2 vols. Fr. 25.)

THIS new edition of M. Guyon's well-known work has been so much enlarged that it has been found necessary to divide it into two volumes, the first of which is now before us. The volume is divided into two parts. The first part is headed On Functional Symptoms, and comprises eleven lectures in which the various disorders of micturition are successively dealt with. The subject of retention of urine alone occupies nearly 200 pages, and under this heading are discussed in turn the several diseases of which retention is a symptom, the chief of them being of course stricture of the urethra and enlargement of the prostate. In the second part, on Pathological Modifications of the Urine, the examination of the urine both in health and in disease is considered in detail, not only from a clinical point of view in relation to the various diseases which give rise to changes in the urine, but also with regard to histology, bacteriology, and chemistry. All these matters are dealt with in the fullest and most elaborate manner. In illustration of this it may be mentioned that over twenty large pages are devoted to the various theories which have been advanced in connection with the ammoniacal changes which take place in the urine. This part of the work also contains numerous illustrations of urinary deposits, some of which show fairly well, whilst others are indistinct, partly owing perhaps to their being printed on the same paper as the text.

The work, if the standard of this first volume be maintained, will, without doubt, be very valuable. Like all M. Guyon's writings, it affords instant evidence both of the author's careful methods and of his large practical experience in the diagnosis and treatment of urinary diseases. The book will certainly be highly valued by those, whether physicians or surgeons, who are specially interested in the subject. The general practitioner, on the other hand, will probably find it too large and too elaborate for ordinary use. But there is another drawback to its general usefulness as a work of reference which cannot be overlooked, and that is the absence of an index. From the manner of its arrangement, it will easily be understood that the book is one which essentially requires a complete index, and it may be that the second volume will to some extent remedy this defect by providing an index for both volumes; but it is, in our opinion, indispensable for the proper use of any work of this size that each volume should have its own index, more especially when the volumes are published separately, as in the present case. We must not omit to add that M. Guyon gracefully acknowledges the valuable assistance rendered him in the preparation of his important work by MM. Camperon, N. el Halle, Chabre, and Albarran.

BLOOD SERUM THERAPY AND ANTITOXINE. By GEORGE E. KRIEGER, M.D. Chicago: E. H. Colegrove. 1895. (Cr. 8vo, pp. 70. 1 dollar.)

FOR those who wish to read a short sketch of the history and application of serum therapeutics, Dr. KRIEGER's book will prove of some interest. He has gone into the question especially after reading German and some Italian literature on the subject; but, so far as one can gather, his own investigations have been confined to clinical and microscopic observations. Perhaps this does not detract much from the value of the work, as for this reason the author is able to give an unbiased opinion on many of the points raised. Some of the photographs illustrating the various organisms are exceedingly good and are well reproduced.

On completing the perusal of the work, however, the feeling arises that many gaps have been left which, had they been filled, would have added considerably to the value of the work as a whole. This is the more to be regretted when it is considered that the part of the book that has been done is not only accurate, but interesting; the incompleteness of this

work, indeed, is its main drawback, though there are points as regards the clinical history—as, for example, the statement that the tonsils, and not the posterior surface of the uvula, is the position in which the first indications of the diphtherial process are usually manifested—which appear to be somewhat loosely expressed. These, however, are merely minor details.

THE FEMALE OFFENDER. By PROFESSOR CESARE LOMBROSO and WILLIAM FERRERO, with an introduction by W. DOUGLAS MORRISON, Her Majesty's Prison, Wandsworth. London: T. Fisher Unwin. 1895. Illustrated. (Demy 8vo, pp. 340. Price, 6s.)

WE have got into a habit of using towards women a language of conventional compliment, and ostentatiously giving up all points in their favour. This is often taken up seriously by men who derive their opinions from what they hear and read and not from what is presented to actual experience. In this way in disputes between men and women injustice is sometimes done to the stronger sex. From such weakness Dr. Lombroso is entirely free. He does not conceal his low estimate of ordinary women. They are big children; their evil tendencies are more numerous and more various than those of men but they generally remain latent. They are less sensitive than men; they feel pain less; they feel grief less; they are less active. They are more vindictive than men; they are crueler when they can get revenge; they are more avaricious in household matters, and more inclined to cheat and to blab secrets, and to commit petty thefts. Women have a latent antipathy to one another, and are very prone to jealousy. Their eminent virtue in Lombroso's eyes is their maternal affection. Female criminals are less common than male criminals, but then the female born delinquent is worse than the male. The authors have studied female offenders by the usual methods of criminal anthropology, and, adding the published observations of others to their own inquiries, they have accumulated a heap of facts, many of them of trifling value. The female criminal has a smaller skull and less cranial capacity than the normal female. The face is more irregular and the lower jaw heavier; the senses are duller. The female criminal presents fewer marks of degeneration than the male. Occasional female offenders are more numerous than habitual ones. For five males in civil prisons in England there is but one female. The authors range prostitutes with born criminals, but most of the former class are the victims of unhappy circumstances and social conditions. They are simple and facile rather than wicked, and most of them would be glad to renounce their miserable trade and have a permanent male protector. The authors have collected many anecdotes about wicked women, but probably worse stories could have been raked together to show the depravity of the male delinquent.

It seems strange that this work on "female criminals" should have been translated into English when Lombroso's *L'Uomo Delinquente*, a much superior book, has not been so distinguished. The female offender hardly deserves a separate treatise.

ELECTROPHYSIOLOGIE. [Electrophysiology.] Von W. BIEDERMAN, Professor of Physiology in Jena. Kräte Abtheilung. Jena: Gustav Fischer. 1895. (Royal 8vo, pp. 448. M. 9.)

TURNING over the pages of this bulky tome, which is only the first volume of a work to be completed within the next few months, we are at once struck with the contrast between the electrophysiology of to-day and that of forty-three years ago, when Bence Jones introduced to English readers, in a little volume of 214 pages, the painstaking researches of Du Bois-Reymond. Looking into the contents of the volume a little more closely, the conclusion forces itself upon one that it is likely to hold its place for many years to come in the laboratory as well as in the library, embodying as it does a very clear and complete account of electrophysiology in general, and of the Hering school in particular.

It may confidently be predicted that the volume before us (and still more the companion volume that is to follow) will in the near future serve as a frequent base of operations, gathering together as it does within a convenient compass

the building materials of hypotheses that have already been proved to be extremely palatable; and, what is perhaps of still more permanent value, inviting the further endeavours of actual workers at point after point of the demarcation boundary between positive and subpositive phenomena, between what is known and what is supposed.

In several important respects BIEDERMANN'S book marks clear and definite advance, the subpositive of yesterday is to-day, a positive position beyond which a subpositive "reconciliation" impossible yesterday is made possible and lawful to-day.

Biedermann, while fully recognising the true value of Du Bois-Reymond's lifelong labours, roundly rejects his "molecular hypothesis," and, taking his stand upon the "alteration theory" of Hermann, protrudes the tentacles of intellectual imagination a little further along the line of current brought into being by his master Hering; and in more than one instance it would appear as if a tentacle had caught on. The "positive Nach-Schwankung" of Hering, Du Bois-Reymond's anomalous polarisation current—proved by Hermann to be due to an after-anodic action current—Biedermann's own antimotor effects on veratrinised muscle and upon unstriated muscle, the familiar excitatory action of the kathode at make and of the anode at break, and the reversed or "inhibitory" action of the anode at make and of the kathode at break, are all utilised by Biedermann in support of the conclusion (p. 375) that the excitation of nerve gives rise to two simultaneous and opposite processes in muscle—excitatory or dissimilatory, and inhibitory or assimilatory.

Gaskell's positive variation by vagus excitation, Bayliss's and Bradford's submaxillary variations, the results of Biedermann's own observations on the secretory variations of the skin and of mucous membranes, are also invoked in favour of the same or of a similar conclusion, "that a given epithelial cell may be electromotive now in one and now in the opposite direction;" "that each cell must be regarded as the seat of two different chemical processes," one giving a positive variation, the other a negative variation of the normal current, which last must in fact be regarded as an action current due to the greater effect of one or other of the two opposite chemical changes alluded to. It must be confessed that this conclusion as presented by Biedermann appears very probable, and that the weight of his evidence in its favour goes a long way in the direction of proof. The further question whether this opposition of nerve effects upon glands may be extended to muscle, whether in point of fact we may admit the obviously opposed processes of tissue integration and of tissue disintegration to be administered by different and functionally opposed nerve fibres—anabolic and katabolic according to the designations promulgated in this country—is left open by Biedermann, and we may expect evidence and argument in favour of such a conclusion to be forthcoming in a second volume.

It is not possible to do justice to Biedermann's work within the compass of a brief notice of the first moiety. The work must be read slowly and carefully. We have only briefly alluded to one or two positive points, the comparative novelty or interest of which happened to give us pause in going through the volume.

An excellent bibliography is given at the end of each section. As might have been expected, the work is well up to date, not only as regards German labours, but also French and English contributions, in illustration of which may be mentioned the observations of Cash, Yeo, and Burdon Sanderson on the latent period and duration of contraction of the heart; of Page and Burdon Sanderson on the electromotive action of the frog's heart; of Waller and Reid, Bayliss and Starling on the electromotive action of the mammalian heart; of Waller, Bayliss, and Starling on the electromotive action of the human heart; of Morat and Toussaint, of Chauveau, of Bradford and Bayliss, and of Reid, on electromotive action attendant upon secretion; of Reid and Tolpitt on the electromotive properties of the skin of the eel.

PRESENTATION.—Dr. G. F. Aldous has been presented by the members of the Plymouth Public Dispensary with a combined barometer and thermometer as a mark of appreciation.

NOTES ON BOOKS.

Health Notes for the Seaside, with Special Reference to Whitley and District. By O. A. DUTT, B.A., M.B. Cantab. (Whitley: Horne and Son. Fcap. 8vo, pp. 61. 6d.)—These health notes on such subjects as habits, clothing, food, etc., though no doubt useful, are not very novel. That we should breathe through our noses and "keep our mouths shut," that "garments should never be worn," that "Dr. Jaeger's woollen clothes are good," that "invalids should not stand about in the open air," that "a contented mind is conducive to refreshing slumber," that "the drainage of a house must not flow towards, but away from it," that "sea bathing is most healthful in suitable cases," are statements, the truth of which is not likely to be called in question. Certain other statements made by our author are not quite so self-evident. We doubt, for instance, if the Registrar-General would admit that "cold weather always lessens the mortality!" "Pipes are more injurious than cigars and cigarettes; a pipe after breakfast, one after lunch, and two before bedtime will not do any harm," that alcohol causes "contraction of the visceral blood vessels," "never drink on an empty stomach," "alcohol and tobacco are in a certain sense antagonistic, that is the one counteracts the evil effects of the other," are statements even more open to controversy.

Affections Chirurgicales des Membres: Statistique et Observations. Par le Dr. POLAILLON, Chirurgien de l'Hôtel Dieu, Professeur Agrégé à la Faculté de Médecine de Paris, Membre de l'Académie de Médecine. (Paris: Octavo Deim. 1895. Royal 8vo, pp. 810; figures 24. Fr. 12.)—This is a statistical record with comments here and there on cases of special interest, of the work done by M. Polailon during the past fourteen years, first at the Hôpital de la Pitié, and more recently at the Hôtel Dieu. The volume, which deals only with the injuries and affections of the limbs, will be followed, it is stated, by another of similar scope on the surgery of the trunk. The statistical matter has been carefully compiled and arranged, and the observations on the more important cases will be found instructive. This book, from the amount of clinical material treated by the author and his large staff of assistants, and from the able manner in which he has reviewed the results of his experience is likely to prove useful to those engaged in hospital work and surgical teaching.

Diabetes and its Treatment. By A. VINTRAS, M.D. (London: Baillière, Tindall, and Cox. 1895. Cr. 8vo, pp. 24. 2s. 6d.)—This small book may perhaps be best described as a series of notes on diabetes, as it does not deal at all exhaustively with any single part of the subject. The treatment is the part most fully described, half the book being given to it. Dr. Vintras strongly advocates Dr. Martineau's treatment, consisting of lithia and arsenic. He has used this treatment during the last five years, and it has given him such unexpected and unhopd-for results that he desires to make it more widely known. The author concludes with a series of diet rules, which take into consideration not only the articles of diet permitted to the diabetic, but also the varying degrees of digestibility of these articles.

Heart Inflammation in Children. By OCTAVIUS STURGES, M.D., F.R.C.P. (London: John Bale and Sons. 1895. Cr. 8vo, pp. 88. 3s. 6d.)—These Lumsden Lectures, which were published in the BRITISH MEDICAL JOURNAL at the time of their delivery by the late distinguished physician, treat of a subject of considerable interest, as heart disease in children presents points of difference from the disease affecting adults. The first lecture deals with the various forms of heart disease seen in children, the second with its physical indications, and the last with diagnosis and treatment. The term *carditis* is employed by Dr. Sturges as synonymous with *endocarditis*. He observes that rheumatic heart inflammation in children is almost always, as the evidence of morbid anatomy shows, both endocardial and pericardial, the myocardium being also frequently involved in late stages. Acute and chronic carditis are both described; the former, rare in

adults, is important on account of its sudden onset, rapid course, and high mortality in children. The author endeavours to ascertain the earliest signs of endocarditis in children—a point of considerable interest and difficulty. He also shows by *post-mortem* evidence that mitral stenosis is a lesion too frequently diagnosed at the present time. Dr. Sturges agrees with Dr. Cheadle that subcutaneous nodules are of bad prognostic omen. In treatment salicylates are useless. The ice treatment proposed by Dr. Lees is discussed at some length, but no definite conclusions are drawn. These lectures are of great practical value. They plainly show that there is still much to be learnt in this important subject when it comes under the analysis of an experienced and observant physician.

Kurzer Abriss der Percussion und Auscultation [Short Summary of Percussion and Auscultation]. Von Dr. HERMANN VIERORDT. 4te verbesserte Auflage. (Tübingen: Franz Pletzcker, 1895. Demy 8vo, pp. 80. M. 1.40).—This small work describes auscultation and percussion as applied to the various organs of the body in health and disease. The section on percussion deals first with the lungs, then with the heart, and finally with the abdominal organs. It includes a short discussion on the various theories of percussion, and under it the different organs are mapped out on the surface of the body. Under auscultation the lungs are chiefly dealt with. The information obtained by percussion and auscultation in diseased conditions is detailed and the significance indicated. No mention is made of auscultatory percussion. The work also includes sections on the special differential diagnosis of pulmonary diseases and on physical diagnosis as applied to the heart and aorta. The subject matter is always treated in a succinct and satisfactory manner.

The Tippler Pigeon Up to Date. By ARCHIBALD F. HEPWORTH, M.A., L.R.C.P., L.R.C.S. (London: King, Sell, and Bailton. Cr. 8vo.)—The breeding of several varieties of pigeons has, Mr. Hepworth contends, all the essential qualifications to be considered in the selection of a hobby. In the first place, he says, it must be within your means; in the second place, it must differ as much as possible from your daily routine work; and, lastly, it must be instructive and amusing. He might have added that it is a very good thing when your hobby is of such a nature as to take you out of doors, and make you indulge in fresh air. Tippler pigeons resemble tumbler pigeons in a good many respects. Their speciality is that they will remain on the wing and apparently immobile to the eye for as many as eleven and sometimes fourteen hours. They are probably a cross of the almond cock and the black and mottled tumbler hen. Mr. Hepworth, who was one of the leading breeders and patrons of tumblers, gives in this little handbook a very good account of these interesting pets and the way to breed and manage them. There are some good illustrations showing the points of the best types, among them two of the tipplers belonging to Mr. Ernest Hart, who holds at present the champion cup for all England. Darwin would have delighted in the tippler pigeon, for none is more beautiful and few display in a more remarkable way the evolution of a new and prominent type, and the adjustment to environment and selection. In many of the varieties of special pigeons, medical men hold prominent positions as successful breeders, and there can hardly be a more agreeable and interesting hobby.

St. Bartholomew's Hospital Reports. Edited by SAMUEL WEST, M.D., and W. J. WALSHAM, F.R.C.S. Vol. xxx. (London: Smith, Elder, and Co. 1894. Demy 8vo, pp. 430).—As usual, the senior members of the staff of the great city hospital are in a minority amongst the authors of contributions to this volume. Dr. Gee has prepared a report of a case in which an aneurysm of the ascending part of the aortic arch took the natural position of the heart. From Dr. Lauder Brunton's paper it would seem that hydroxylamine hydrochloride is preferable to nitroglycerine and the nitrites in the treatment of angina. Mr. Thomas Smith contributes a remarkable report of a case in which a large sarcoma was successfully removed from the middle of the thigh of an adult male. Mr. Putin affords us a good summary of a second

Year's Surgery at St. Bartholomew's Hospital. The most valuable passages in this memoir refer to the radical cure of hernia. Among the contributions of younger men we must give an honourable mention to Mr. M'Adam Ewing for his monograph on the great omentum. Dr. Hubert Roberts writes on the History and Present Position of Symphysiotomy. The essential value of his memoir lies in a series of investigations made on dead subjects as to the effects of dividing the symphysis. Dr. Herringham's article on Primary Cancer of the Pancreas is, perhaps, the best type of paper for a work of this kind, since the writer has ransacked the *post-mortem* and clinical notebooks of his hospital for cases of the disease in question and unearthed no fewer than 17, all under treatment since 1882.

Medical Electricity. By H. LEWIS JONES, M.A., M.D., Medical Officer in charge of the Electrical Department, St. Bartholomew's Hospital. (Second Edition. London: H. K. Lewis. 1894. Cr. 8vo, pp. 448, 100 illustrations. 10s. 6d.).—We welcome the second edition of this excellent manual of which Dr. Jones now assumes sole authorship. Medical electricity occupies a humbler position in applied therapeutics than it deserves. The difficulties connected with the management of the apparatus, and a certain want of general knowledge as to what can and what cannot be accomplished by its use, and its certain inability to work miracles have caused many to shut their eyes to the whole subject, or to look upon it with coldness. Dr. Jones's manual will go a long way to remove all these difficulties, and especially those on the last count. His elucidations are clearly and temperately given, and he is not afraid of disclaiming the merits of any particular treatment. His introductory chapters on apparatus and general principles will be welcome to the less technical of his readers. For its size and general scope it is certainly the best textbook with which we are acquainted.

The Volunteer Surgeon's Guide. By Surgeon-Captain R. R. SLEMAN, Artists R.V. (London: Wm. Clowes and Sons. 1895. Fcap. 8vo, pp. 95. 3s. 6d.).—This little book contains a great deal of information that volunteer medical officers will find very useful. In a concise and intelligible way are brought together all the regulations affecting the volunteer medical service, and the duties and responsibilities of all ranks are fully explained. We notice on page 37 that the badge of the stretcher-bearer is described as a white web band with "S. B." upon it, to be worn on the left arm. According to the present regulation, the badge consists of the letters "S. B." in a monogram in red and blue upon a white ground enclosed within a red circle an inch and a half external diameter, worked in worsted on the same material as the tunic, and it is to be worn on the right arm above the elbow. This error is probably due to the book having been published before the issue of the regulation, as otherwise it is quite up to date.

Poisons: their Effects and Detection. By A. W. BLYTH. Third Edition. (London: Chas. Griffin and Co. 1895. 8vo, pp. 701. 21s.).—This edition bears evidence of careful revision throughout, and is as complete a treatise on the subject as anyone need wish to read. It appeals, no doubt, more especially to the chemical expert, but still, in the frequent references to pathological specimens in one or other of the London museums and in the sections on treatment, there is abundant material to interest the student or busy practitioner. That it has been brought well up to date is evident from the fact that the report on opium eating in India which appeared in our pages not long since is quoted, whilst full notice is taken of the treatment of morphia poisoning by permanganate of potash, and the *post-mortem* imbibition of arsenic is discussed. We do not find, however, any mention of the treatment of snake poisoning by strychnine which has been used in some of the Australasian colonies. The only mistake we have come across is that Lamson is said to have murdered his victim in 1881, whereas the deed took place in 1882. In the appendix some concise directions for treatment in the different forms of poisoning are given.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DENTISTRY, AND THE
ALLIED SCIENCES.

A NEW UREAMETER.

Fig. 1. The accompanying illustrations show the shape of the instrument. It is held in the position shown in Fig. 1, and about half filled with hypobromite solution. One c.c. of urine is put into the little test tube, which is then placed in the larger open end of the ureameter, and this is corked up. By turning over the whole thing in the direction of the hands of a clock to the position shown in Fig. 2, the urine is mixed with the hypobromite solution and the whole of the nitrogen given off is registered by the level of the liquid in the graduated tube. After reading the indication by turning round the instrument still further in the same direction as before, all the hypobromite solution which has not been in contact with the urine may be emptied back into the stock bottle. It is evident that with this ureameter none of the nitrogen escapes into the open air, and the amount of hypobromite solution used is very small. The instrument is made by Messrs. Mayer and Meltzer, 71, Great Portland Street, London.

Mr. C. J. MAYER, student of medicine in King's College, London, claims that a new ureameter which he has designed possesses the following points of advantage: It is extremely portable and simple, but it nevertheless estimates the amount of urea in urine with accuracy, moreover, only a small amount of sodium hypobromite solution is required for each estimation. The accompanying

illustrations show the shape of the instrument. It is held in the position shown in Fig. 1, and about half filled with hypobromite solution. One c.c. of urine is put into the little test tube, which is then placed in the larger open end of the ureameter, and this is corked up. By turning over the whole thing in the direction of the hands of a clock to the position shown in Fig. 2, the urine is mixed with the hypobromite solution and the whole of the nitrogen given off is registered by the level of the liquid in the graduated tube. After reading the indication by turning round the instrument still further in the same direction as before, all the hypobromite solution which has not been in contact with the urine may be emptied back into the stock bottle. It is evident that with this ureameter none of the nitrogen escapes into the open air, and the amount of hypobromite solution used is very small. The instrument is made by Messrs. Mayer and Meltzer, 71, Great Portland Street, London.

Another advantage claimed for this pattern is that free egress is given for shreds of membrane, owing to the openings being so wide and owing to the fact that the inner tube, being formed by fixing a strip of metal to the one side of the tube, it takes up very little space. Further, the end *b* *c* has been made conical to facilitate introduction into the uterus, and the side openings are of such a length as to show how far the catheter has been passed into the uterus. Mr. Edgar finds that the three most convenient sizes are: small, c.c. 2½ in., *b* No. 15, English catheter size, and at the point No. 10; intermediate, c.c. 2½ in., *b* No. 20, and point No. 12½; large, c.c. 3 in., *b* No. 24, point No. 17. The large size is useful in cases of abortion, polyp, etc., the two others in eroding the uterus. The smallest size can be passed without preliminary dilatation. The instrument is made by Messrs. Young and Son, of Edinburgh, who charge 7s., 8s., and 9s. for the several sizes.

A NEW BAG FOR THE INDUCTION OF PREMATURE LABOUR AND OTHER OBSTETRIC OPERATIONS.

The use of Champetier de Ribes's bag is attended with certain drawbacks. In the first place, its size when distended within the uterus must displace the foetal head, and very probably the placental circulation is also frequently disturbed. Secondly, the distention effected is entirely dependent on the onset of the uterine contractions, and these sometimes do not commence for twenty-four hours after its introduction. To remedy these drawbacks Messrs. Allen and Hanburys have made for Dr. John Shaw, obstetric physician to the North-West London Hospital, a dilating bag, which is represented in the accompanying figure. It will be seen that the bag is really a double one, in shape resembling a Barnes's bag, but with a disc at its uterine end which is capable of separate distension. The bag is introduced into the uterus by means of Champetier de Ribes's forceps and the distal

disc injected with fluid, which prevents the bag slipping out of the uterus. Into the larger bag water can now be injected from a douche reservoir, and this will at once begin to dilate the os with a force dependent on the height the reservoir is raised above the patient, whilst the rhythm of pains can be imitated by alternately raising and lowering it. Dr. Shaw believes that the bag will be found of use not only in the in-

AN IMPROVED INTRAUTERINE CATHETER.

Mr. JOHN EDGAR, M.A., B.Sc., M.B., C.M., Clinical Assistant to the Gynaecologist, Glasgow Royal Infirmary, has introduced a modified form of Bozemann's intrauterine catheter, which he considers presents certain advantages. As in the original form, the solution passes into the uterus by a small inner tube, shown at *c* *d* in the drawing, and, after circulating

duction of premature labour, but also in the treatment of placenta prævia and malposition where it is important to close the mouth of the womb in order to gain time for the rectification of the fetal axis.

SANITARY POWDERS AND SOAPS.

We have received from the Jeyes' Sanitary Compound Company samples of some of their newer preparations for all of which it is claimed that they contain in a perfectly harmless form the active principle of their well-known disinfectant. A surgical dusting powder containing boracic acid and 10 per cent. of creolin seems likely to be useful, it being proposed as a substitute for iodoform, and for use in the same class of cases. It certainly does not possess the same strength of odour as the older substance, but as the properties of creolin are as yet by no means well known, it would seem advisable that further researches should be made before stating definitely its properties.

Of greater general usefulness are the various sanitary soaps made by the same firm among which we may mention their eucalyptus soap. It possesses a pleasant odour, is superfatted, and contains an appreciable quantity of the oil. Savon soap is another which is claimed to be of the highest quality and triple milled.

It certainly seems probable that the continuous use of mild disinfectants by rendering the skin soft and clean at the same time would be followed by good results. But in the absence of any scientific data it is not possible to make any stronger statement.

A NEW VACCINATOR.

Mr. J. Ingham, Macclesfield, sends us a description of a new vaccinator which has been made for him by Messrs. Arnold and Sons. Fig. 1 shows the instrument closed ready for use. Fig. 2 shows the part with grooves and needles *in situ*, raised from a hinge joint. The other end is a blunt lancet with a shallow groove for the reception of lymph.

Fig. 1.

Fig. 2.

As needles can be had in every house, the advantage of this vaccinator will be easily seen, this being a great improvement on the old type of vaccinator of this description when the needles are permanently fixed and the great difficulty is keeping the points clean.

LITERARY NOTES.

Messrs. DIBBY, LONG and Co. will publish almost immediately *Perfect Womanhood: a Story of the Times*, by Frederick J. Gant, F.R.C.S. The types of womanhood described, which include a nurse, a "Discontented Associate," a female medical missionary, a ritualistic maiden, and others, are presented as the products of the social development which distinguishes the reign of Queen Victoria. The book is dedicated by permission to H.R.H. Princess Christian.

Another instalment of the English translation by Dr. A. F. Hoernlé of the *Boyer Manuscript*, the origin and character of which were described and illustrated in the *BRITISH MEDICAL JOURNAL* of June 1st, p. 1216 has been published. This includes leaves 14-13 of the Sanskrit medical work *Adhvanyaka*. The translation has been executed on the same plan as that of the earlier leaves, and with equal ability and care.

On the recommendation of the Indian Government, a good service pension has been conferred on Surgeon-Colonel D. Spencer.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The Bacteria of Diseases.—Steps in Discovery.—A Commercial Development.—Aboriginal Inhabitants of Jamaica.—Oysters and Typhoid Fever.—Abnormal Children.—Measurements in Schools.—Future Meetings.

On Monday evening Professor FRANKLAND gave an address on the work of Pasteur. After an introductory statement dealing with his earlier work, the Professor reviewed Pasteur's connection with the foundation and development of the infant science of bacteriology and his contributions to our knowledge of infectious diseases.

THE BACTERIA OF DISEASES.

Soon after he had commenced to study the bacteria of particular diseases he was impressed by the fact that often in the course of cultivation in artificial media outside the body their virulence became diminished to such an extent that they ceased to be fatal on inoculation into susceptible animals, but the most important discovery in this connection was that the animals inoculated with such enfeebled or attenuated cultures were found to have become protected from the disease even when subsequently inoculated with the most virulent cultures of the same organism. This discovery at once enlarged the scope of Pasteur's investigations, which now included not merely the study of infectious diseases and their exciting causes, but embraced also the artificial protection of the individual against their attack. The most varied methods were devised and elaborated for attenuated viruses of different kinds, and multitudes of domestic animals were protected from some of the most destructive plagues with which they are afflicted. Pasteur next proceeded to grapple with a disease affecting both man and animals, that is, hydrophobia. This problem was surrounded with special difficulties, over which, however, the genius of Pasteur triumphed, and the attenuated virus of hydrophobia was successfully prepared, and by several different methods. As a testimony to the faith which experience has built up in the efficacy of the treatment we find centres for carrying it on in almost every civilised country in the world, whilst at the Institut Pasteur in Paris it is carried out on an enormous scale. The great problem of securing immunity from disease, which thus occupied the later years of Pasteur's activity, has, however, now entered upon an entirely new phase. For while Pasteur's methods depended essentially upon submitting the individual to be protected to the attack of the disease-producing organism itself in a weakened form, the new methods of conferring immunity do not involve any contact whatever between the individual and the virus in any shape or form.

STEPS IN DISCOVERY.

The cardinal step in this new method of treatment is the discovery that the artificial cultures of pathogenic bacteria may be entirely freed from the micro-organisms and yet produce their characteristic poisonous effects; the symptoms of a particular infectious disease can be obtained through the injection of the toxic or poisonous products elaborated outside the body by the particular micro-organism associated with that disease. By this discovery the toxins of diphtheria and of several other diseases have been rendered as specific poisons as are laudanum or the extract of nuxvomica. It was further found that animals can be gradually accustomed to these specific toxins, and the question then arose as to how such animals which had undergone this gradual habituation to a particular toxin would behave on being subsequently inoculated with the disease-producing organism itself. It was found that such animals were able to withstand or were protected from the attacks of such virulent bacteria. This important step we owe to the labours of Salmon, Roux, Chamberland, and other investigators. The next step was the discovery that the blood of an animal thus artificially protected from a particular disease contained materials which can be transferred to other animals and protect them also from the same disease. This astounding property of the blood serum of artificially immunised animals was first discovered by Kitasato and Herington, but to Behring and Kitasato is due the credit of having first shown in the case of

diphtheria and tetanus that, by means of such serum, animals may be cured even after the disease has been actually contracted, provided the injection of the antitoxic serum is not postponed until too advanced a state of the malady has been reached. Again, to Behring is due the merit of having extended these benefits in connection with diphtheria to man himself. The lecturer then referred to a diagram showing the diphtheria death-rates per one million living in the principal cities of the United Kingdom during the years 1883-1892 and 1893 respectively. In commenting upon these statistics it was pointed out how in London the figures had risen from 300 in 1883-92 to 700 in 1893, whilst in West Ham, virtually a part of London, an increase from 250 to 420 in deaths from diphtheria had also been recorded. As indicating the value, so far ascertained, of the serum treatment of diphtheria, he quoted Kossel's recent figures giving the mortality from diphtheria in Germany before the introduction of the new treatment as 34.7 per cent., and since its application as 11.1 per cent. A fact of great importance to be observed in this new treatment of diphtheria is the circumstance that its efficiency is greatly dependent upon the time which elapses between the first manifestation of the disease and the application of the curative serum. The shorter the period which intervenes the better the results which are obtained, and this condition applies equally to the treatment of other diseases, such as tetanus, by means of antitoxic serum, whilst it has also been established as a cardinal principle by Pasteur in his treatment of hydrophobia.

A COMMERCIAL DEVELOPMENT.

So great is the demand for the therapeutic serum for diphtheria that its production is already a commercial undertaking of great magnitude in Germany, where coal-tar colour manufacturers, with their numerous staffs of skilled chemists, have still further enlarged their works by undertaking the elaboration of diphtheria antitoxic serum on a most extensive scale. The possibilities of securing protection by means of the serum of immunised animals extend even beyond the boundaries of infectious disease, for Calmette, in France, and Fraser, in Edinburgh, have been able to gradually accustom animals to larger and larger doses of snake venom, and have found the blood serum of such animals endowed with the power of protecting other animals into which the venom is injected. When we remember, said the lecturer, that 20 000 of our Indian subjects perish annually from snake bites and that the new method of treatment extends the prospect of saving many, if not all, of these, it is obvious that we are here again face to face with a subject of stupendous importance and which affects us above all the other nations of Europe. In conclusion Professor Percy Frankland pointed out the widespread influence which Pasteur had exercised upon the progress of science during the latter half of the present century, and that this extraordinary influence wrought in so many different departments of science must be attributed in the first instance to the possession of a singularly active, clear, and original mind matured under the strict discipline of an early training in mathematics and the exact sciences, which enabled him to submit biological phenomena to such a rigid, logical, and uncompromising criticism, such as they had never previously received. But even this rare combination of natural and educational endowments would have availed but little had there not been united to them an almost superhuman industry, an almost limitless capacity for work. It would be difficult also to find a better illustration of the manner in which one science can benefit from contact with another than that which is furnished by the results which have attended the digression of the specially trained chemist into the fields of biology and medicine. To Louis Pasteur belongs the glory of having set in motion that great medical revolution which has been well sketched by a modern French writer:

"When man learnt how to protect himself from the wild beasts he made the first step in civilisation. To-day man is learning how to defend himself from microbes; it is a step of equal importance. A day will come when in Berlin, in London, in Paris, man will not die of diphtheria, of typhoid, of scarlet fever, of cholera, or of tuberculosis, any more than he dies in these cities to-day of the venom of snakes or of the tooth of wolves."

ABORIGINAL INHABITANTS OF JAMAICA.

In the Section of Anthropology Sir W. H. Flower read a paper descriptive of the remains of the native inhabitants of Jamaica who existed previous to the invasions of the Spaniards, which were discovered recently in a cave by the Rev. W. W. Ramsey on the Halberstadt estate belonging to Mr. B. S. Gossett. This cave, which was of small size, was situated in a wild rocky part of the Port Royal Mountains, about 2,000 feet above the sea level and two miles from the shore. The bones found belonged to people of both sexes and all ages, from children of 5 years up to very old persons, the proportion of the latter being very remarkable. The skulls of nearly all showed evidence of that remarkable custom of flattening the forehead in infancy, which even up to our own time prevailed through so large a part of the American continent. There was evidence that this practice of flattening the skull was done to improve the appearance. From observations made on the few remaining races among which this custom prevails there was reason to believe it had no deleterious effect on the brain, and was probably not so injurious to health as the tight lacing to which fashionable ladies of the present day were addicted.

OYSTERS AND TYPHOID FEVER.

In Section D, Zoology, Professor HERDMAN and Professor BOYCE presented a report upon Oysters and Typhoid: an experimental inquiry into the effect upon the oyster of various external conditions, including pathogenic organisms. The report opened with a statement of motives, objects, and methods, and gave the following summary of the results obtained so far: "Our experiments demonstrate: (1) The beneficial effects of aeration (a) by the addition of air only; (b) by change of water; pointing to the conclusion that the laying down of oysters in localities where there is a good change of water, by tidal current or otherwise, should be beneficial. (2) The diverse results obtained by feeding upon various substances, amongst which the following may be noted: The exceedingly harmful action of sugar, which caused the oysters to decrease in weight and die. The oysters thrive best upon the living protophyta and protozoa. Those fed upon oatmeal and flour after a time sickened, and eventually died. (3) The deleterious effects of stagnation, owing to the collection of excretory products, growth of micro-organisms, and formation of scums upon the surface of the water. (4) The toleration of sewage. It was found that oysters could, up to a certain point, render clear sewage contaminated water, and that they could live for a prolonged period in water rendered completely opaque by the addition of faecal matter; that the faecal matter obtained from cases of typhoid was more inimical than that obtained from healthy subjects; and that there was considerable toleration to peptonised broth. (5) The infection of the oyster by the micro-organisms. The results of the bacteriological examination of the water of the pallial cavity of the oyster, and of the contents of the rectum, showed that in the cases of those laid down in the open water of the bay the colonies present were especially small in number, whilst in those laid down in proximity to the drain pipe the number was enormous (for example, 17,000 as against 10 in the former case). It was found that more organisms were present in the pallial cavity than in the rectum. In the case of the oysters grown in water infected with the bacillus typhosus, it was found that there was no apparent increase of the organisms, but that they could be identified in cultures taken from the water of the pallial cavity and rectum fourteen days after infection. It is found that the typhoid bacillus will not flourish in clean sea water, and our experiments seem to show so far that it decreases in numbers in its passage along the alimentary canal of the oyster. It would seem possible, therefore, that by methods similar to those employed in the "Bassins de dégorgeement" of the French ostraculturist, where the oysters are carefully subjected to a natural process of cleaning, oysters previously contaminated with sewage could be freed of pathogenic organisms or their products without spoiling the oyster for the market. It need scarcely be pointed out that if it becomes possible thus to cleanse infected or suspected oysters by a simple mode of treatment which will render them innocuous, a great boon will have been conferred upon both the oyster trade and the oyster-consuming public. We

desire to acknowledge the kind help of Mr. W. I. Beaumont in making some of the observations at Port Erin, and of Mr. Andrew Scott at Liverpool.

ABNORMAL CHILDREN.

Dr. FRANCIS WARNER read in the Section of Anthropology the third report, drawn up by himself, of the Committee on the Mental and Physical Deviations of Children, which, since its formation in 1888, has examined and reported upon 100,000 children. In the third report are given the results of research among 8,941 children, 5,112 being boys and 3,829 girls. Defects in development of the body were found to be more frequent among boys than girls, the proportion being 8.7 to 6.8. A marked exception to this rule was in the case of small cranium, which were much more frequent among girls. This defect appeared to some degree endemic in the neighbourhood of large buildings, and was less frequent among Irish children.

MEASUREMENTS IN SCHOOLS.

Dr. GABSON read the report of the Committee on Anthropometric Measurement in Schools. He said it was desirable that this work should be done on a common basis, and if schools in any particular locality were willing to undertake it Professor Windie, the secretary of the committee, would be pleased to supply forms and explain the system adopted.

FUTURE MEETINGS.

At the General Committee Meeting the President was in the chair, and amongst those present were Sir F. Bramwell, Mr. W. H. Preece, Sir H. Trueman Wood, Sir C. Tupper, Sir John Evans, Dr. Fream, and Mr. Conrad Cooke. Mr. Griffith, the assistant secretary, had certain formal matters to bring forward, but the principal business was to fix the place of meeting for the year after next, and elect officers for the Liverpool meeting next year. The invitation to visit Toronto in 1897 was renewed, the matter having been fully entered into last year. Communications were now read from learned societies in British Columbia, Montreal, and Manitoba, strongly urging the Association to go to Toronto. In the absence of the Mayor of that City, at present ill in Yorkshire, Sir CHARLES TUPPER made the necessary explanations as to the character of the arrangements that would be made in the Dominion, and he was followed by Mr. Cody, the City Treasurer of Toronto. On the motion of Sir F. BRAMWELL, seconded by Professor HICKS, supported by Mr. VERNON HARCOURT, it was unanimously resolved to go to Toronto in 1897. Bournemouth and Dublin were mentioned as possible towns for 1898. Sir Joseph Lister was, with general acclaim, elected President for Liverpool next year, and Lord KELVIN, in making the motion, said that the mortality in hospitals had been largely reduced by the labours of this great representative of biological science and medicine. Professor SCHAFER, the successor to Sir Douglas Galton, as general secretary, seconded the resolution; and amongst the Vice-Presidents appointed were the Lord Mayor of Liverpool, Lord Sefton, Lord Derby, and Sir H. Roscoe. The date of meeting will be September 15th.

THE GERMAN TRIALS OF WATER FILTERS.

THE Prussian War Office has recently published an interesting report by Dr. Plagge, on investigations on which he has been engaged during the last ten years in respect to the capacity of water filters to prevent disease. So far back as 1886 Dr. Plagge tested all the then available filters. He found, as all other observers have found, that the German carbon, natural stone, gravel, sand, cloth, sponge, paper, and asbestos filters were entirely useless. In the case where he examined filters from England, as with spongy iron, and the Maignen carbon filter, he obtained the same result. During the last four years he has undertaken a renewed investigation of modern forms of filters, and it is to the results of this investigation that the present report owes its chief interest.

Beginning with the carbon filters of Bähring and other German makers, he remarks not only the same incapacity to prevent the passage of organisms as he had found previously, and as has been repeatedly indicated in the columns of the BRITISH MEDICAL JOURNAL, but also the same tendency on the part of the makers to make false claims for their

apparatus as unfortunately exists at present in this country. The Maignen Filtré Rapide, composed of a carbon preparation and asbestos, had been tested by Dr. Plagge's predecessor, and found entirely useless in the prevention of disease. The paper, cellulose, and asbestos filters, including the well-known Austrian filters of Breyer and numerous other makers, were equally found permeable to disease organisms.

The Pasteur filter was only examined incidentally. The author, while describing it as in the fullest degree satisfying all sanitary requirements, and as necessarily the standard for all later constructions, was attracted to the exceptionally large output yielded by some of its later imitations. The imitations of the Pasteur filter in porcelain in Germany have been numerous, but, according to Dr. Plagge's results, hitherto unsuccessful—a circumstance which is interesting to us in this country, where the advent of such imitations may be expected to follow on the increasing use of the Pasteur filter.

The chief body of the report is devoted to the experiments with the Berkefeld filter. Dr. Plagge was attracted by the enormous output of this filter; and, apart from a preliminary investigation, of which he thinks the results cannot be at present fairly considered as final in the light of the improvements which were subsequently made in the filter, he has had them at work and under bacteriological observation for three years. The preliminary observations were sufficiently hopeful to warrant the experimental use of specimens of them in an African expedition. They were found to be unsuitable for this service; and in the present year, being again tried in the portable form, were still found to altogether fail. We must say that we think the circumstances under which these filters were used, while necessarily conclusive as to the unsuitability of the filters for army purposes, were considerably more trying than many in which the use of a filter is indicated. It is in the tables of the experiments made by Dr. Plagge in his laboratory, where the conditions of manipulation by competent persons and treatment of water less difficult to filter than that which was used on the field trials, were at least as favourable to the filter as those which would occur in ordinary domestic use, that we find the materials for pronouncing a definite judgment on the practical value of this filter.

The tables extend over sixty pages, and relate to the examination of 38 specimens of Berkefeld filter tubes. Of these, 37 were put into actual use, and examined after periods varying from five days up to six or seven months. The output was in almost all cases found not only to be initially very high, but also with periodical cleaning at short intervals to remain so for long periods. In respect, however, of capacity to arrest microbes, and of mechanical strength, the results obtained may be thus summarised. Of the 37 filters successively set to work, 4 passed microbes directly, and were consequently not further examined; 5 did so before the end of the trials, varying from five days up to three or four months; 1 during the trials passed microbes within eight to ten hours from the time of sterilisation; 3 did so from the outset within twenty-four hours. Of the remainder, 16 passed microbes within twenty-four hours from sterilisation at some time previous to the termination of the trials, varying from five days up to seven to eight months. In 2 such cases the filters were examined hourly, and it was found that the organisms passed within the fourteenth and eighteenth hours respectively.

From these circumstances Dr. Plagge concludes that it is indispensable for the Berkefeld filter to be cleaned and thoroughly sterilised by boiling either once or twice in twenty-four hours, according to the extent to which it is used. During his own examinations the cleaning and boiling were at irregular intervals, but amounted approximately to the same extent of treatment. The net result was that of the 37 filter tubes used, no less than 27 got broken during their respective trials, varying from nine days to seven to eight months from their commencement. These results, obtained in the case of tubes submitted by the makers for experiment, and handled by persons accustomed to the manipulation of sensitive apparatus, are probably at least as favourable to the filter as those which would be obtained by persons to whom the care of filters would ordinarily be entrusted in

practice. While these experiments were going on six Pasteur tubes were under similar examination for eight months, but none were broken.

It therefore appears that, out of the 37 filters 20 first or last passed and remained within twenty-four hours of sterilisation or less, 2 of them directly, while 27 were in a more or less short time broken. Apart from the expense of renewals of filter tubes which such breakage would cause, it is impossible to entertain the adoption of a filter which in many cases is incapable of giving any protection at all against the passage of microbes, and is liable after use to lose its initial capacity to arrest such passage within a few hours of sterilisation.

The results obtained by Dr. Plagge confirm and extend those of Dr. Johnson's research on the same subject, and appear to show definitely that the larger output of the Berkeley field filter is obtained at the expense both of mechanical strength and of capacity to resist the passage of microbes. There is the less reason at the present time to seek for these exaggerated outputs, as the installation of Messrs. Debenham and Freebody visited by members of the Public Health Section of the British Medical Association at their last meeting, showed in a practical way that any desired daily output can be very simply obtained from the Pasteur filter itself. Dr. Plagge's report shows clearly the risks which may be incurred in dallying with alternatives of less efficiency than that of the rigidly adequate standard which Pasteur has supplied.

RECLAMATION OF WOMEN DRUNKARDS: THE EXPERIENCE OF THE PAST YEAR.

THE fifteenth report of the Inspector of Retreats under the Inebriates Acts for the year 1894 was published on September 17th. Respecting the work done at Fallowfield, the Manchester Retreat for Inebriate Women, the inspector gives the following remarks of the licence:

"The Grove is one of the largest retreats for women open under Government licence. It is visited by an inspector appointed by the Crown. Rich and poor patients are received; the former paying for their board, the others paying smaller sums and employing themselves in useful and remunerative work. There is abundant need for such retreats. Among the well to do alone, no domestic miseries are more hopeless, and few more frequent, than those which are caused by the father or mother being a drunkard; probably the drunkenness of the mother is the saddest of all. Again, it is painfully common for a woman to be brought before the Bench scores and hundreds of times for being drunk, and punished over and over again with short terms of imprisonment. Imprisonment in such cases is the most futile of resources; the poor creature is released just when the pains of debauch are over, and the craving for drink has returned, but too early for any cure of her disease, moral or physical, to have been made. The fact cannot be too frequently reiterated that nothing short of prolonged restraint from the use of stimulants—until the craving has died away, and the constitution recovers its normal condition of health—is of any avail as a remedy. Even the twelvemonth prescribed by law proves not a day too long.

"The following figures will describe the work of the Grove during the year ending December 31st, 1894:

Number of applications ...	124
Number admitted ...	24
Left after a year's stay ...	28
At present in the Retreat ...	35

"The methods adopted at the Grove are simple and natural. They are immediate and entire abstinence from strong drink, strict regularity of life, constant and cheerful employment, gentle firmness, and unflinching sympathy, and a religious influence always present and often directly urged. The Grove and its beautiful grounds form bright and healthful surroundings, while skilful and kindly medical help is always at hand, thanks to the unflinching kindness of our honorary medical advisers. It may be of interest to note that among the patients we have had one in whom the habit of cigarette smoking was combined with inebriety; another case was complicated by the opium habit. It may be added that our experience has confirmed what has often been proved before that even in the case of the worst habitual drinkers, no harm, but the reverse, is done to the

health by the sudden and complete disuse of all alcoholic drinks.

"It is a common opinion that when once a woman has taken to drink recovery is impossible. It is therefore natural for the question to be asked, How far has the Grove achieved success? Do the patients who leave us stand firm? Before answering this question it should be remembered what sort of patients we receive. They are not persons who have just begun to drink to excess, and have suddenly awoke to their peril. Such persons do not seek refuge in a licensed retreat; they try, often vainly, to recover themselves by other methods. The patients who come to the Grove are those who have run their course, and come to utter misery. They are often destitute and outcast from their friends, broken down in health and self-respect, and utterly degraded. They are the wreck of womanhood. They are among the worst cases that can be dealt with. If, then, we find that 25 per cent. is the average proportion of patients who give evidence of permanent recovery, we need not express either wonder or regret. The wonder is that so many should stand firm, considering the abundant temptations which meet them upon leaving the Grove in the allurement of the ubiquitous liquor trade and the pernicious customs of society. And it should further be mentioned that if one of our old patients is known to take stimulants in ever so small a quantity she is recorded in our books as relapsed, although she may not be known (as yet) to have become an inebriate. It is, meantime, an enormous comfort to the committee and workers at the Grove to receive frequent letters and visits from former patients, who testify to the blessings they have received. Four women who left in 1891 (our first year) still remain steadfast abstainers, and are doing well in their several stations in life. Six who left in 1892 have stood firm; nine from 1893."

The inspector strongly urges the necessity of the Government making the admission to such institutions compulsory, and not voluntary as at present.

DEATHS UNDER ANÆSTHETICS.

CHLOROFORM.

DR. C. E. SALT has forwarded to us the following particulars of a case of death under chloroform which occurred at the Salop Infirmary on September 10th:

J. F. P., a patient admitted on September 7th to the Salop Infirmary for treatment under Mr. Eddowes, the senior surgeon. He was suffering from cancer of the penis complicated by enlarged glands in the penis. He had nothing abnormal in heart or lungs, but was considerably emaciated by his disease, and apprehensive of his safety under operation. On the following Tuesday, September 10th, chloroform was administered in the usual way from a drop bottle, and at first the patient took it well, but after three or four minutes' inhalation, one of the surgeons who was holding the patient's pulse informed the anaesthetist that it had suddenly become very poor, and immediately the chloroform was removed. He was only slightly under the influence of the anaesthetic, and up to this time his breathing and appearance had been good, the first sign of danger being the flagging pulse. Paralysis of the respiratory centre followed almost immediately on cardiac failure. On the first alarm the patient's head was brought over the end of the table and artificial respiration at once commenced and continued for an hour, but the patient showed no signs of resuscitation, and it is believed that he died almost immediately. Faradism, ether, and strychnine subcutaneously, ammonia and amyl nitrite to the nose were also made use of, but without effect. It is the opinion of the medical men present that death was due to cardiac failure, while partially under chloroform, induced by a nervous apprehension of the operation.

THE Exchange Telegraph Company have issued a *Poll Book* giving the results with figures for the last four general elections. Owing to the numerous changes which have taken place recently, such a volume is likely to be extremely convenient. The Company have long been well known for the accuracy as well as the speed of their work, so that the statements may be relied on. The book is to a small extent a literary curiosity, since it has no title page, and we must therefore perforce, in spite of Mr. Bailey's recent denunciation of such a practice, quote it by the title on the cover.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 426, Strand, London. Post-office Orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, SEPTEMBER 21st, 1895.

INOCULATIONS AGAINST CHOLERA.

PROFESSOR HAFKINE's system of inoculation against cholera has had another year's trial in India, and he is now returning to Europe. His results have been published by Dr. Simpson, M.O.H. of Calcutta, in a report to the Chairman of the Corporation of Calcutta (see page 735).

From the time the Hafkine system was first introduced into Calcutta till July 15th, 1895, 4,397 persons have been inoculated in that city with the following remarkable results. In 36 houses in which cholera appeared a certain number of the inhabitants were inoculated, but the majority remained uninoculated. These houses furnished valuable means of observation as to the definite value of inoculation as a preventive against cholera in times of epidemic. The total number of the inmates of the 36 houses was 521; of this number 181 were inoculated and 340 not inoculated. Among the uninoculated there were 45 cases with 25 deaths, or 11.64 per cent., and among the inoculated there were 4 cases with 4 deaths, or 2.2 per cent. Of these 4 cases none of the patients had undergone a second inoculation and 3 of them contracted cholera and died from 1 to 4 days after the first inoculation and before the protective influence of the vaccine had had time to assert itself. In spite of this, however, the figures show that the not inoculated were 6.08 times more liable to attack and 5.27 more liable to death from cholera than the inoculated.

During the First Eight Days.

	Average Number Present at Date of Attack.	Cases.	Per Cent.	Deaths	Per Cent.
Not inoculated ...	75	8	8.00	4	5.33
Inoculated ...	13	3	5.77	3	5.77

After Eight Days.

	Average Number Present at Date of Attack.	Cases.	Per Cent.	Deaths	Per Cent.
Not inoculated ...	295	39	14.72	25	12.91
Inoculated ...	140	1	0.71	1	0.71

It must be remembered that two injections, one five days later than the other, are necessary for full protection, the first

with the weak vaccine, and the second with a stronger vaccine which requires another five days to secure complete action. The figures in the table showing the results of inoculation before and after the first eight days are very remarkable.

Dr. Simpson adds that "after eight days, and in fact after five days, the difference in liability to attack becomes very marked, the inoculated living in the same houses in Calcutta being 20 times safer from attack, and 18 times securer from death, than the not inoculated should cholera enter the house. This is protection of a very decided character. No case of cholera occurred among those who subjected themselves to both inoculations."

The facts regarding the Gya Gaol, the Cawnpore and Lucknow outbreaks and anti-choleraic inoculations are recapitulated, and a number of new facts are given as to the inoculation of large numbers of coolies in the Assam tea gardens by Professor Hafkine.

The work undertaken in Assam by Professor Hafkine has been simply colossal, and it has been carried out with a devotion, a singleness of purpose, and an expenditure of private means, unusual even in the domains of medicine and science. In the Karkaria Tea Garden there were among the uninoculated 5 cases and 2 deaths, among the inoculated 1 case and 1 death. In the Kalain Tea Garden there were among the uninoculated 22 cases and 10 deaths, and among the inoculated 2 cases and 1 death. In the Chargola Gardens among the uninoculated 3 cases and 1 death, and among the inoculated no case. In the Kalachera Garden among the uninoculated 4 cases and 3 deaths, and among the inoculated 1 case and 1 death. In the Pallarbund Garden, among the uninoculated 2 cases and 2 deaths, and among the inoculated no case. In the Degubber Garden, among the uninoculated 2 cases and 1 death, and among the inoculated no case. In the Adam Tilla Garden, among the uninoculated no case, and among the inoculated 2 cases and 1 death.

Summarising the observations made on the gardens on coolies inoculated once, that is, before the second inoculation was applied, the results are—among the uninoculated 38 cases and 19 deaths, and among the inoculated 5 cases and 3 deaths.

The original report, which we publish in full on page 735, must be consulted in detail to ascertain the value of these figures, and also of the 36 observations made on houses in Calcutta.

Dr. Simpson concludes the report, urging the Commissioners to make a further grant of 10,000 rupees, in order to prosecute the inquiry, and to place anticholeraic inoculation on a thoroughly satisfactory basis. He adds: "By granting facilities to carry out this important work in the capital of India, which is regarded as the centre of the 'home of cholera,' and the city of all others in the East, to which Government turns for information concerning this disease, as indicated in the scientific missions of Koch from Germany, Klein from England, Zahn from Geneva, and Shakespeare from America, the Commissioners will not only be conferring a public benefit on the inhabitants of Calcutta, who are so subject to cholera, but they will also be leading the way to the introduction of a prophylactic measure which, either in its present or in a modified form, may be expected to effect an enormous reduction in the ravages of cholera among Eastern and Western populations."

THE MEMORIAL TO SIR ANDREW CLARK.

In the *Times* of September 13th appeared a lengthy extract from the *Hospital*, headed "Mismanaged Memorial." In this extract is given what purports to be the history of this memorial, setting out that the expressed determination to raise £12,000 for the erection of isolation wards and a new pathological department at the London Hospital, as a memorial to its late distinguished consulting physician, and President of the Royal College of Physicians, had issued in the collection of barely £3,000, and that at the quarterly court of governors of the London Hospital, held recently, those responsible had abandoned the form of memorial originally set forth, and had substituted an erysipelas ward for women, another for isolation cases, and increased accommodation for the porters. It adds that those responsible for the decision ought to feel heartily ashamed of themselves that they should propose to erect a building for the accommodation of the male servants of the London Hospital as a memorial to Sir Andrew Clark. This article was followed on the next day by a letter in the same paper from "A Subscriber," adding: "Several of us considered that the memorial was being mismanaged, but we never thought that it would degenerate into the perpetuation of Sir Andrew Clark's name by means of a building for the accommodation of the male servants of the London Hospital." The letter reflects, also, on the manner in which the business of the memorial had been mismanaged. Extracts from the article in the *Hospital*, with comments thereon, have also appeared in the *St. James's Gazette* and other papers.

These statements and animadversions have been met by a letter which appeared in the *Times* of September 17th, signed by Mr. Hale, the Chairman of the House Committee, and Mr. John Henry Buxton, the Treasurer of the London Hospital. In this, amongst others, two things are pointed out: In the first place, that the sum actually raised falling so far short of that necessary for the original idea agreed upon by the subscribers' Committee, the question was how best to carry out, as far as the funds permitted, the intention to erect a block of isolation wards to bear Sir Andrew Clark's name and to be of permanent benefit to the suffering poor for whom Sir Andrew Clark laboured at the London Hospital for so many years. Something of the aims of the memorialists had to be sacrificed, and something had to be added to the sum collected to enable the project to be carried out in any way. The governors of the hospital—who had, it may be mentioned, already contributed handsomely to the fund—were therefore asked at the recent quarterly meeting to sanction the expenditure of £1,500 for the foundations and half basement which would necessarily have to be constructed before any wards could be built on the site proposed. Were this not done very little could be done for the £3,000 collected for the memorial. In the basement accommodation will, if the plan is carried out, be provided for the male servants of the hospital; and this is the only ground for the statement that the memorial to the late Sir Andrew Clark had degenerated into provision for the accommodation of the hospital porters. It was a hearty desire to help to carry out the wish of the memorialists that led the House Committee to get the permission of the governors to the expenditure of £1,500.

In the second place, it is made quite clear by the letter

of the authorities of the London Hospital that whilst they have been doing their best to give facilities to carrying out the wishes of the subscribers to the Andrew Clark Memorial, the final determination does not rest with them. They say that directly the governors had given their approval to the expenditure of the £1,500 for the foundations and basement, on September 4th, the architect was instructed to work out plans. "These," they add, "must be fully considered, and, if suitable, will of course be submitted to the Andrew Clark Memorial Committee, with whom, as the representatives of the subscribers, the approval or otherwise of the memorial must rest, and not with the House Committee."

It must, of course, be a matter of deep regret to the friends and admirers of the late Sir Andrew Clark and the subscribers and Committee of the memorial that the sum actually raised falls too far short of that necessary for fully carrying out the original plans, and so inadequate to the recognition of the work and worth of the late Sir Andrew Clark. It would not be profitable at the present time to enter into the circumstances which, in the opinion of those best acquainted with the facts, have led to the failure of the hopes of those who have taken the most active share in promoting the memorial. H.R.H. the Duke of Cambridge most graciously, on the first intimation of the proposal, desired to associate himself with the intention to honour the memory of Sir Andrew Clark, and Mr. Gladstone and his family did all in their power to promote it. Mr. Gladstone addressing a large public meeting when scarcely physically equal to the task is most gratefully acknowledged, and Mr. Gladstone's estimate of Sir Andrew Clark's life and work, and his generous testimony of the aims and labours of the medical profession, remain on permanent record. The Committee, we believe, has striven its best to make the Andrew Clark Memorial worthy of the great physician whom it was desired to honour, and it is not obvious that it has failed in any legitimate efforts, whilst it is to be regretted that these efforts have not been attended with a greater measure of success.

THE FOREST GATE DISTRICT SCHOOLS.

We regret to have to record that these hapless schools are again suffering from an epidemic of scarlet fever, which has already assumed serious proportions, something like fifty children having been attacked in the last three weeks. The managers seem to be doing all that is possible to isolate and remove the patients and thus minimise the danger of infection, but when so many children are congregated under one roof the conditions are not only specially favourable to the spread of disease in the ordinary way, but the children themselves are peculiarly liable to contract it. As we have more than once pointed out, there is no material at hand from which conclusions could be scientifically adduced as to the value of different methods of bringing up those of the young who by inheritance or early neglect necessitate special consideration if they are to be made fit to be self-supporting. On entering one of these large institutions the children are neither weighed nor measured. The angry mother or the disappointed philanthropist may affirm, as they frequently do, that the child has wasted to a shadow while he was under the guardians' care, but that body has no facts by which the statement can be refuted. Whether

children physically develop best when drilled, fed, housed, and washed in barrack schools or whether they grow and strengthen more when subdivided into groups is still a matter of opinion only.

The Local Government Board has never seen fit to give its medical officers instructions to observe and tabulate facts with an accuracy that could enable them to form a judgment sufficiently supported to countenance action. But the general consensus of opinion among those who have had experience with institution children is that they do not grow, strengthen, and develop with the same rapidity or freedom as children brought up under natural conditions, and the extent to which epidemics spread if once they get a footing is a factor which goes far to support this opinion. At this season of the year, when every sandy bay and rocky beach gives abundant examples of the undivorced union between health and interest, it is not difficult to realise that young creatures whose lives are necessarily divided from every natural interest and excitement should lose one of the first and most essential aids to robust vigour.

Exercise is most effectively taken when it is taken pleasantly; but the games that can be played in the playing yards of such a school as Forest Gate are at the best but a dull amusement, and their monotony soon robs them of such stimulation to energy as they might have originally possessed. The children rarely walk beyond institution boundaries, and when they do the large numbers necessitate semi-military marching at a pace suitable to the youngest and feeblest, and therefore inexpressibly wearying to the elder and stronger.

We have mentioned only the absence of varied and interesting exercise as a reason why institution children should be less robust than those living under normal conditions. But we argue without data—data which could be readily supplied by the medical officers of the pauper schools if the Local Government Board would furnish them with instructions to weigh all children on admittance, three months after they enter, and at period intervals during their residence within the school. The normal size, weight, and strength capacity of an ordinary child is an ascertained datum, and could be compared with the institution-bred child; thus, or only in similar ways, can it be ascertained whether the dietary tables, the sleeping accommodation, and all the other details of the large organisation are suitably arranged to promote the health of the children of the State. Without such information we can but go blundering along, probably making mistakes of vital importance to the child which closer watching could have remedied without trouble or expense.

INSANITY AND CRIME.

THE trial of Robert Allen Coombes, a lad aged 13, upon an indictment and coroner's inquisition charging him with the wilful murder of his mother, was concluded at the Central Criminal Court in London on Tuesday last. The jury found that he was guilty of the act charged but that he was insane at the time he did the act so as not to be responsible at law for his actions. Whereupon Mr. Justice Kennedy, before whom the case was tried, ordered the youthful matriarch to be detained in strict custody as a criminal lunatic until Her Majesty's pleasure should be known.

As far as one may rely upon the press reports of the trial

the jury could not well have come to any very different conclusion, and, on the whole, the outcome of this sad case is about as well as could have been under the circumstances.

Perhaps the necessarily condensed reports of the trial are misleading on the medical aspects of the case, and therefore the little we say is expressed under reserve.

The lad had been clever at school and well behaved; "he was a very good boy;" was the testimony of his teachers. Complaints of headache at times, the condition of excitability observed on occasions, the statements that he had heard noises at night, the fondness for sensational literature and for criminal trials; harbingers perhaps of mental disorder, as in some cases, are not necessarily so; and, by themselves, as a previous history, are merely suggestive.

The defence chiefly rested on the medical officer's observations made on the youth in prison since his arrest for the crime, on which was based evidence to the effect that he was insane, or at all events recurrently so, with lucid intervals. Mental excitability, changeability, and peculiarity were manifested; an erratic letter was written; and, to a leading question whether he heard voices, he reply was that voices at night told him to "kill her, kill her, and run away."

Accepting as valid the conclusion that he was insane, one still would like to know how it came about that in prison and on trial for murder a lad of 13 years and of his station in life hit upon the formula "that he felt an irresistible impulse to kill" his mother. And, in fact, according to his own statements the murder was premeditated and skilfully planned, as well as cold-blooded and callous in its execution and concealment.

Sensational criminal literature is most pernicious in its influence on the weak-minded or the lunatic at large, and there is some evidence that in the present case it was harmful.

INEBRIETY AND INSANITY.

THE large part played by alcohol as a cause contributing to insanity receives fresh confirmation in the fortieth report of the Commissioners in Lunacy. For the five years ending 1893 alcoholism was the predisposing or exciting cause in 20.8 per cent. of male and 8.1 per cent. of female lunacy. Intemperance is credited with 25.6 per cent. of male and 19.9 per cent. of female general paralytics.

JENNER CENTENARY IN RUSSIA.

It is announced by the Russian National Health Society that next year it is intended to commemorate the centenary of Jenner's first experiments in a special way. It proposes (1) to offer four prizes for the best works on vaccination; (2) to collect and publish materials for a history of the practice of vaccination in Russia and a short history of the same in Western Europe; (3) to publish a Russian translation of Jenner's works, accompanied by his biography and portrait; (4) to organise an exhibition of objects connected with vaccination, and to hold a commemorative meeting on the day of the centenary.

ENGLISH SURGERY IN BURMAH.

AMONG the benefits which the Pax Britannica confers on those Eastern races who become constituent members of the British Empire not the least is the introduction of Western methods in the treatment of injuries and diseases. The antiquated theories and crude appliances which have persisted in the changeless East for countless generations are contrasted with the most advanced methods of the practical

West, and the natives are not slow to read the object lesson. A striking instance is afforded by the success of the General Hospital, Burmah. During recent years there has been a wonderful increase in the number of patients applying there for treatment, due not to increase of population or of sickness, but to the realisation by native sufferers of the fact that they are sure within the walls of the hospital to meet with kindly and skilful treatment. The hospital is well found, its floors are polished, and its wards furnished with excellent system of bath, douches, etc., with cold and hot water. The number of operations performed in one year in the last report is stated to be 209, of which 179 were major operations. There was only one death after operation out of this number—a fact which reflects the greatest credit on Brigade-Surgeon-Lieutenant-Colonel Hugh Johnstone, and goes far to account for the growing popularity of the hospital.

CALISAYA DRUNKARDS.

CALISAYA drunkards are stated to be rapidly increasing in number in New York. It is said that there is very little calisaya in the mixture, and that the drinker is practically drinking alcohol and quinine. There seems to be a general ignorance of what this beverage really is, persons sometimes resorting to it in the hope of a cure for alcoholic drunkenness. This calisaya drink is, however, more injurious than a purely alcoholic liquor when taken to excess—then the drunkard really suffers from the effects of an overdose of both drugs. The tinnitus aurium of the quinine is accompanied by the circulatory riot of the alcohol. This is much the same concoction as the spirit and bark which, under the name of "Peruvian," was much affected in the city referred to a quarter of a century ago.

THE REVISION OF THE "INDIAN ARMY MEDICAL REGULATIONS."

THE sixth volume of the *Indian Army Regulations*, which pertains to Medical Services is undergoing revision, as is also the *Field Service Manual*; to bring both up to date, is a very necessary step. We believe that the new *Army Regulations for the Treatment of Cholera*, sharply satirised by Mr. Hart at the Indian Medical Congress, and recently at the Public Health Section of the British Medical Association in London, forms part of this volume. It undoubtedly needs much revision.

BURIED ALIVE.

THE subject of the alleged burial of persons who are still alive has recently proved as fruitful as ever of barren correspondence; not one shred of evidence in support of their belief has been proved by those who write so glibly of what would certainly be, if there were any truth in their assertions, an unspeakable horror. We would make an earnest appeal to require from correspondents some sort of proof before inserting letters on this subject. When a man writes: "How often are careless doctors censured by coroners for giving certificates without seeing the body?" and "In how many cases in ordinary practice is the examination merely perfunctory?" we ask ourselves what can the man who penned such sentences be thinking about? He never can have seen a death certificate or he would know that it is not necessary to see, much less to make any examination, however perfunctory, of the dead body, and we hope that no coroner ever yet censured a doctor for not doing that which he has no obligation to do; of course if a medical man gives a certificate in the case of a person he has never attended during life he would lay himself open to a censure from which no amount of looking at the body after death could save him. We see no objection to the death certificate being made more stringent, as this would imply greater accuracy in our statistical tables of the cause of death, but if the Home

Secretary should see fit to take any steps in this direction, we think that the time would be a fit one to institute payment by the State for death certificates, seeing that there is no reason why medical men should perform this service for the State gratuitously. The question of cremation which is raised is an entirely separate one.

THE COST OF A CRIMINAL FAMILY.

IMPROVEMENT of the social status of our population, and attempts to lessen pauperism and criminality, are matters of general and widespread interest. Practical measures are needed to counteract inherited tendencies in certain families, as well as in cases of habitual drunkards and frequent offenders. The suggestion of such measures is generally met with the objection of their costliness to the public, without regard to the expenses thrown upon the public purse by the existing degraded portions of the population, as well as in other ways. The chief constable of Chester has given the record of John Ogden, recently dead, who made 130 appearances before the city justices; 86 being for drunkenness, and 44 for assaults. Ogden's father appeared before the bench 35 times, a sister 67 times, and another sister 20 times. The father, son, and two sisters, were charged 347 times; it has been estimated that in the expenses of prosecutions, prisons, and Poor-law maintenance, the Ogden family have cost the City of Chester £2,000. Such cases are frequently met with, and demonstrate the grave importance of accurate inquiry as to the physical and mental conditions of the population. Inquiries conducted by a committee of the British Medical Association, show that many such cases may be detected in our schools; which provision for their proper care in early years and subsequent provision might prevent much evil. The consideration of the mentally and morally feeble portions of the population claims the early attention of the Government.

THE GUARDIANS' GUARDIANSHIP OF THE POOR.

OUR oft-repeated contention that the poor suffer because the nursing provided in the workhouse infirmaries is inadequate is enforced by the experience of the past week. At Yarmouth, notwithstanding the protests of lady guardians, "there is only one room set apart for the nursing of sick children, no matter from what disease they are suffering," and "that single room, which is used as an infirmary for children, has also to serve as a nursery for babes." A correspondent signing herself Ethel Leach writes to the *Eastern Daily Press*, drawing attention to the "cruelty" of sending "children with sore heads to be nursed in the same room with measles and whooping-cough." The medical officer has, it seems, asked in vain that further accommodation may be provided. From Coventry comes the familiar tale of a letter from the Local Government Board, reiterating the opinion already expressed to the guardians on more than one occasion, that the number of nurses in the house, both as regarded imbeciles and the ordinary sick, was "insufficient," followed by the equally familiar remark, "the communication was ordered to stand over." Finally, the *Thanet Guardian*, in the report of an inquest on the death of a pauper in Bstry Workhouse, tells how, in the absence of a nurse, a patient fell and struck his head; how the nurse, being summoned, was again called away; and how at last the patient died with only a neighbouring patient at his side, and without having seen the doctor. The nurse's excuse was that she had to "attend a child in the women's ward." The jury condemned the nurse; but when shall we hear of a jury brave enough to condemn guardians who overwork the staff, or refuse to supply necessary accommodation? It is astonishing that such things should happen, and it is clear to our mind that the public conscience is ignorant of the facts. Good well-meaning people who pay their rates, and who feel pity for the sick and are tender over children's weakness, do not conceive how officialism

hardness the guardians' action. They cannot understand how men who are kind to their own children and thoughtful to their own sick can be so "cruel" as to use the nursery as an infirmary, or to leave the dying to die untended. But that it is so, these, among many other instances, serve to prove; and that it will be so until the present class of guardians are superseded by cultivated as well as kind-hearted people who will come forward to give the time and take the trouble which is involved in becoming a guardian of the poor. Medical men and workmen are needed on such Boards, but they, as well as business men, can hardly be expected to join until the hours fixed for the meetings are beyond working hours. To change the hour of meeting would be a simple reform, but one which might have some far-reaching results.

NUNS AS NURSES IN IRISH WORKHOUSES.

The question of the nursing arrangements in the Irish workhouses, of which we shall have to speak from personal investigation in the next few weeks, is just now occupying a good deal of public attention. The *Irish Independent* contains many letters on the subject, and the circular of the Local Government Board has agitated the Boards of Guardians considerably. The want of trained nurses has aroused a discussion as to the qualifications of the Sisters of various Roman Catholic orders, who in many cases manage the workhouse hospitals. At Athlone the Local Government Board have refused to sanction the appointment of one of these ladies as night nurse on the ground that she is not trained. The guardians proposed to have her trained in a Dublin Hospital; the Local Government Board assented, but the Bishop refused to permit the arrangement, because it is against the rules of the order to undergo training in the manner required. The guardians then declared that they would adhere to the appointment of the lady mentioned, in spite of the threat of the superior Board to dissolve them. At Ballinasloe the guardians have agreed to appoint a night nurse who has received the requisite training. We shall be able to bear testimony to the good services of the Roman Catholic sisters in the Irish workhouses; but we must strongly declare that they should be required to undergo the full ordinary training that is now required in every hospital. A peasant can suffer just as much as a town patient; he requires just as much skilled nursing, and he ought to get it. When our reports on the various workhouses come to be published, it will be seen that the present system is a very bad one, and that the guardians and the Local Government Board in Ireland must face a big public question, no matter how unpleasant it may be.

THE SMALL-POX EPIDEMIC IN DUBLIN.

In the report of the Local Government Board for Ireland for the year ending March 31st, 1895, Mr. T. T. Stafford, the medical inspector for the Dublin district, presents an interesting and important paper on the small-pox outbreak. He notes that between 1871 and 1881 there were 2,988 deaths from small-pox, while from 1882 to 1893, both inclusive, only 5 deaths occurred. The outbreak of 1894 was undoubtedly caused by a casual admitted to the North Dublin Union, who was, within four days of his discharge, admitted to the Hardwicke Hospital. This person refused to give any information as to the places at which he had stayed or where he had come from, and the authorities were therefore unable to deal with the lodging houses in which he resided. Cases from the workhouse and from the city soon began to drop in, until on March 31st, 1895, 1,251 cases had been treated in hospitals, with 88 deaths, or 11.03 per cent. Thirteen deaths occurred outside, which would represent about 143 persons attacked, or, in all, 1,394 cases. In 1843 Dr. Watt declared that, before 1800, 20 out of every 100 children born perished from small-pox. In the present epidemic no vaccinated child under 9

years died of the disease, the effects of primary vaccination upon the child population being thus strikingly apparent. In 47 vaccinated cases where death resulted, 53 per cent. had only one scar; 63 per cent. had three, but in no single case was it recorded that death resulted in a person vaccinated in accordance with the standard laid down by the Local Government Board. During the period of the epidemic about 40,000 persons were revaccinated. Of these 20 were subsequently admitted to hospital suffering from small-pox, but in not one of these cases had revaccination been performed more than 14 days previously to the onset of the disease, so that it may be said that no successfully revaccinated person contracted small-pox. The total staff of doctors, nurses, and attendants who were in direct contact with small-pox in Cork Street, Hardwicke and Kilmainham Hospitals numbered about 110; of these all save two had been recently revaccinated or had had small-pox. Both of the nurses who had not been revaccinated contracted small-pox, and not one of the rest of this large staff, although living for months in an atmosphere of small-pox, was attacked. This report establishes again the advantages to be obtained from revaccination, and Dr. Stafford has proved his conclusions by carefully compiled figures which cannot be controverted.

SICK POOR IN PROVINCIAL WORKHOUSES: BASINGSTOKE.

It seems that the Board of Guardians of the Basingstoke Union is aware of some of the defects in their present treatment of the sick and infirm in their workhouse, defects which our Commissioner's report show to be sufficiently glaring. But we also learn from that report that a certain number of guardians incline to the adaptation of the old infectious hospital as sick quarters, instead of the right and proper course of building a new infirmary. It is clear that before this old building could be made even tolerably suitable, much money must be spent on it, and then it would be but a makeshift, as the situation is bad. The ratepayers should look into this, since a loan for a thirty years' term could be obtained from the Local Government Board for new buildings, while no such help would be given for adapting the old ones; and as the public conscience is really waking up at last, the adaptation would probably be condemned in a few years' time, and the money spent on it thus absolutely wasted. Nurses' quarters for a sufficient staff will, it is to be hoped, form part of the improvements. The present staff is largely supplemented by pauper help, and the post of the night nurse who died recently has not been filled, presumably because there is nowhere that she can sleep out of hearing of the wards.

MATRICULATED STUDENTS AT SCOTTISH UNIVERSITIES.

PARAGRAPHS about Ordinance No. 147, which contains the regulations as to matriculated students, have been going the round of the papers, lay and professional, and they have been printed in such incomplete form as to give rise to misapprehension. It has been supposed that the effect of the ordinance on men coming up for the M.D. degree, for example, would be to compel them, not only to matriculate for the year, but to be in actual attendance on one or more classes in the university. To medical practitioners this, of course, would be an impossibility. We have had several anxious inquiries sent to us on this point. For answer it is only necessary to print the ordinance in question in full. The second clause clearly settles the question. "No person shall be deemed to be a matriculated student in any university or shall enjoy any of the privileges of a matriculated student unless, in addition to paying the matriculation fee, he is enrolled as a student in attendance in one or more classes in the university, and has paid the fees entitling him to such attendance: Provided that nothing herein con-

tained shall affect the right of the University Court to exact a fee in lieu of and not exceeding the matriculation fee from any candidate for any examination or for graduation, not being at the time a matriculated student, in addition to the fee payable for such examination or graduation."

THE NATIONAL HEALTH SOCIETY.

THIS Society will commence its special training course on Tuesday, October 1st. This special training is intended to qualify ladies for posts as factory or sanitary inspectors, lady lecturers, etc., and consists of lectures on elementary anatomy and physiology, first aid, nursing, domestic and personal hygiene, sanitation, and public health. Examinations are held on the various subjects, all students being required to satisfy the examiner in each subject before receiving the diploma of the Society. Students not requiring the full diploma can attend the lectures on any of the above subjects and will receive certificates on examination.

WASTEFUL BURIALS.

WE have often drawn attention to the reckless extravagance indulged in by the poor over the burying of their dead. The subject was recently brought before the notice of the Middlesbrough guardians, in consequence of applications for relief being made by widows who were known to have received considerable sums from clubs on the death of their husbands only a short time before. In one case, according to the *Poor-Law Officers' Journal*, a widow had £12 from clubs at her husband's death, and she spent £7 10s. over the funeral, having one mourning coach and five cabs. In a second case a widow with four children had £11 from the club, and spent £7 4s. on the funeral, having two mourning coaches and three carriages. A third case was that of a widow with four children, who got £12 6s. from clubs. She spent £7 15s. over the funeral, having one mourning coach and three carriages. Three weeks after the funerals most, if not all, of these people had neither food nor money. It would seem as if the arrangements for these funerals were largely left in the hands of friends, who considered it their duty to get rid of the club money as quickly as possible, and to hand the people over to the guardians to be taken care of.

THE MEDICAL COLLEGE AT TIENTSIN.

WE are pleased to observe that the war in the East has not put a stop to the Chinese Imperial Medical College at Tientsin. The examinations, which were held on July 8th and 9th, evidenced a remarkable amount of proficiency on the part of many of the students, numbering at the time, apparently, 22. The war will not be an unmixed evil if it should lead to a more active cultivation by the Chinese of European sciences, even though they are cultivated as aids to war.

PROVIDENT DISPENSARIES.

THERE can be no doubt it is very necessary for members of the profession to be cautious in their dealing with these institutions. They should never forget that, if conducted on faulty principles, they are one of the most powerful of the many influences in their midst which tend to undersell their services. It cannot be denied that a certain number may be necessary for the public welfare, but it might be safely reckoned that a large number of existing ones are quite as much employed for cheapening medical labour, that is, sweating the profession, as to relieve any very pressing public want. An influential committee at Plymouth has been advertising recently for a second medical officer for a newly-established provident department of the Plymouth Public Dispensary, and the remuneration offered is all the contributions of members minus a deduction for expenses. If the contributions are on the ordinary scale this must leave but a bare pittance for the medical officers, and it is a pity that in our large towns some stand is not made by the

local profession to prevent the formation of provident departments in connection with the medical charities, except under the strictest regulations to exclude improper members. These institutions, especially if not well regulated, tend largely to damage the private practice of nearly all the medical men in the locality. We do not know what are the particular rules and regulations of this institution, but from the curt wording of the advertisement, for example, that the officer selected shall be liable to removal at pleasure of the committee, presumably without notice, it may reasonably be conjectured that medical influence is not very strong on the Committee of the Plymouth Public Dispensary, or, at any rate, has not been utilised to safeguard the interests of the profession.

THE CAUSE OF DEATH IN ELECTRIC SHOCK.

A VALUABLE contribution towards the elucidation of this question has lately been made by Dr. Bleile, of America, based upon experiments with twenty-seven dogs. He has once more shown that it is not the failure of respiration, but the arrest of the heart beat, which is the immediate cause of death, thus confirming the results published recently by Dr. Lewis Jones in the *BRITISH MEDICAL JOURNAL*. His figures further show the importance of the duration of the contact in determining a fatal result when the currents are not far removed from the margin of safety. In working near this limit he found that amyl nitrite seemed to increase the animal's power of resistance, and therefore advances the theory that death is not so much due to direct injury of the heart itself, as to the stoppage of the heart following upon a tremendous rise of blood pressure from vasomotor constriction. Dr. Bleile has published no blood pressure tracings in support of his view, and those which accompany the paper quoted above are sufficient to disprove his theory. Atropine did not appear able to avert a fatal result, and this seems to negative the view that the arrest of the heart is due to the effect of the current upon the cardio-inhibitory fibres of the pneumogastric nerve. It is still probable that the current acts directly on the heart by destroying its power of beating rhythmically.

THE SEASON AT CARLSBAD.

THE season which is now on the point of completion is perhaps the most remarkable in the history of this famous Bohemian health resort. The aggregate of "cure guests" registered in the books of the municipality since the beginning of the year has been no fewer than 40,000, a number which has taxed even the remarkable resources of Carlsbad in the way of hotel accommodation and lodgings. The local authorities have done, and are doing, their best to meet the rapidly increasing needs of the town as a cure place for the crowd of visitors who come annually from all parts of the world to drink the waters. A considerable number of fine new villas, fitted up with all modern comforts and the electric light, have been built during the last year in the neighbourhood of the Schlossberg, known as the English quarter. In this part of the town a new park has been laid out, and having been dedicated to the public on Independence Day, under the auspices of a number of Transatlantic visitors, has been called the American Park. A quantity of old houses that stand opposite the Muhlbrunn Colonnade on the other side of the river Tepl are doomed to destruction during the coming winter; and the municipality will thus be enabled not only to widen the carriage road and improve the course of the stream, but to give a much wider avenue in front of the Colonnade for the perambulations, during the early morning water drinking, of the hundreds of visitors who now flock to the Muhlbrunn and other springs. The most important improvement of the year has been, however, the opening of the magnificent Kaiserbad for the farther accommodation of the patients who are ordered sprudel or mud baths. The three bathing establishments already existing for this purpose having proved insufficient, the municipality bought the site

of a brewery not far from the famous Hotel Pupp, and on it have erected from the designs of the Vienna architects Fellner and Helmer a building which is one of the most magnificent bathing establishments in the world. Its exterior is in the style of the French Renaissance; is strikingly handsome in effect. Inside, all the newest and best devices that experience could suggest have been utilised to make the bathing cabins complete and luxurious. In addition to the ordinary cold douche, sprudel, and mud baths, there are electric and steam baths, and there is, moreover, a very complete installation of Swedish hygienic gymnastic apparatus on the Zander system, under the charge of a resident physician. In these and many other respects Carlsbad is keeping abreast of the times, and is maintaining its world-wide reputation as a health resort of the highest type.

SHELTERS AND COMMON LODGING HOUSES.

ALTHOUGH the extent of the operation of the Common Lodging Houses Acts must depend on the construction put on that description, there is no statutory definition of such houses. In Section 116 of the Towns Improvement Clauses Act, 10 and 11 Vict., cap. 34, public lodging houses were defined as those in which persons were "lodged for hire for a single night, or for less than a week at one time," or, "of which any part was let for less than a week." This description would, on the face of it, apply equally to every hotel in the kingdom. In the Common Lodging Houses Act of 1851, as originally drafted by Lord Ashley, was a clause in practically identical terms, but with addition of the words "not being a licensed victualling house," and "in which any room is let for hire to be occupied by more than one family at one time," but it was struck out as incorrect, incomplete, or superfluous. The Local Government Board, in their Model Bylaws and Orders, seem to accept that given by the late Sir A. E. Cockburn and Lord Hatherley, when consulted in 1853 as the law officers of the Crown, in which they make no mention of payments, and attach no importance to the period for which the lodgers are taken in, but insist, as the essential distinction, on the fact that "persons being strangers to one another, that is, not being members of the same family, and promiscuously brought together are allowed to occupy the same room," with the saving clause as regards hotels, inns, and taverns. The General Board of Health, in their supplementary directions and regulations issued on October 12th, 1853, as to the application of the Common Lodging Houses Act of that year, expressly exclude all consideration of the period for which the lodgings are let or lodgers taken, with a view to meet the attempts at evading the Act by longer terms than a night or a week, thus leaving the fact of persons not belonging to one family occupying the same rooms as the sole and sufficient character. The exemption of the charitable or quasi-charitable establishments, subsequently opened by various religious bodies, rests upon a decision in the case of *Booth v. Ferrett* in 1890, 25 Q.B.D., 87. We have not the report before us, but can only suppose that it turned on the assumption that these so-called shelters are presumably not conducted for profit, though the question of profit must depend on the ratio subsisting between the receipts and expenditure, quite irrespective of the amount of the outlay or the payments. Since the Salvation Army shelters are not, or not wholly, free, some charge, be it but a penny, being made, we can see no essential point of difference between them and the licensed common lodging houses to justify their claim to exemption from control and inspection by the sanitary authority. For the better prevention of the spread by their means of infectious disease, these "shelters" must be brought under the Common Lodging Houses Acts, whether by an amendment of the law, a statutory or authoritative definition, or a further judicial decision on a test case. But the most satisfactory and shortest method would, we think, be for the

Local Government Board to issue an order or memorandum defining a common lodging house, on the single point of common occupation of the same room by strangers, promiscuously brought together, excluding only the case of parties conducted and paid for by one of their number, as, for example, a football team or theatrical company on tour. The exemption of a house in virtue of the possession of a licence for the sale of intoxicating liquors is an outrage on common sense. But as regards the Salvation Army shelters, the fact of such overcrowding and the part they have been playing in the present epidemic of small-pox call for prompt and energetic interference. In the four weeks July 7th to August 3rd the patients admitted to the Asylums Boards Hospitals were 209, of which 48 or 49, equal 23 per cent., had resided for the fortnight or more immediately preceding in one or other of the Salvation Army shelters. In the third week no fewer than 106 cases occurred, and of these the Salvation Army shelters contributed 31, equal 29 per cent., that at 272, Whitechapel Road, 22, or 20.7 per cent.; that in Blackfriars Road 10, and others in different parts of London the remaining 12. They are thus seen to be answerable for 23 per cent., and one alone for 14 per cent., of all the cases in the metropolis. It is a public disgrace that such dens should be allowed to exist in the "brighter" London at which all are aiming, and to exist uncontrolled on the pretext of charity or religion, and that an irresponsible and arrogant individual, calling himself "General," with his "majors" and "captains," should be permitted to defy the law and to offer forcible resistance to the authorities even when armed with a magisterial order, in a course of action in which the doubtful good is certainly outweighed by the positive evil and the evident danger to the community at large.

NOTIFICATION IN AMERICA.

AN Act of the Pennsylvania Legislature passed this summer increases the stringency of the law in that State as to the notification of infectious disease and the powers of the municipal authorities for preventing the spread of epidemics. The diseases the notification of which is compulsory are "cholera, small-pox, diphtheria, membranous croup, scarlet fever, typhoid fever, typhus fever, yellow fever, cerebro-spinal fever, relapsing fever, leprosy, varioloid, or diphtheric croup." The maximum penalty is a fine of 100 dollars or in default sixty days imprisonment. Children living in a house in which a person has suffered from diphtheria, small-pox, scarlet fever, cholera, varioloid, diphtheric croup, leprosy, typhus fever, yellow fever, or relapsing fever, or children or other persons who have suffered from one of these diseases are forbidden to attend any kind of school, Sunday schools being specifically named, until thirty days after the recovery, removal to hospital, or death of the person last affected, and the thorough disinfection of the premises. The Act gives power to a municipality to appoint a special person by whom alone a certificate of fitness to return to school may be given, and this power has been exercised in Philadelphia. Very extensive powers are given also to make rules as to isolation of individuals, and as to the mode of disinfection employed, so much so that the *Medical News* states that the health authorities would have it within their discretion to order the destruction of a house if they considered it infected, and to enter "sweat shops" and destroy the articles found therein whenever they deemed it necessary, and without compensating the owners for the loss of the articles destroyed.

THE SANITARY NEEDS OF INDIA.

AN Indian correspondent writes to us: An account of Mr. Ernest Hart's address at the opening of the Public Health Section of the British Medical Association meeting was telegraphed at some length to India by Reuters, which no doubt has selected only the strongest and most sweeping of its propositions. Not unnaturally the publication of the summary has caused a considerable stir among the heads of the

sanitary service in India. I hope when we get the full text we shall find that Mr. Ernest Hart has credited the Indian Medical Service with being a splendid body of men, that have immense influence with the natives, and no one who has not lived in India, and especially up country, can realise what an important part of the Government they practically are owing to this influence with the natives. Most men here agree with him, however, that it is nonsense to call the Indian medical civil doctors a reserve for war times, as it would be simply impossible to carry on the government of India without them as civil servants. The whole subject is one of which the complexity is hardly less than the importance, but the two things which Mr. Hart has plainly indicated and laid great stress on in his addresses here and in those which have since reached us are obviously urgent as matters of reform. In the first place the British Medical Service in India and the Indian Medical Service need to be brought under the same head; for while the British medical officers are demoralized and pining for want of work and want of pay, the Indian medical officers are overwhelmed with work, and get all the plums of the service. Again, the present system of putting the sanitary work of India on army medical officers who are not specially trained for it, and making promotion go by purely military rules, and shifting men about in the most anomalous manner, all this is destructive of real efficiency or economy. Great curiosity is felt to see what will be the result of the radical criticism from an outsider, and, with the exception of a certain minority to whom the multiplication of offices at nominal salaries is mainly a question of income, there is a general hope that the whole question may be thoroughly considered by the Secretary of State for India and by the Government of India in the direction which Mr. Hart suggests.

THE PUBLIC HEALTH CRITIC.

THE *Daily Chronicle*, through one of its leader writers, takes great exception to the last issued report of the medical officer of the Local Government Board, on the ground of its "five hundred pages of microscopic portents;" its pages "teeming with bacilli, metabolic products," etc.; and because the writer of the article when seeking "for visits paid to crowded districts," for problems relating to "pestilential areas," could find none. Indeed, he says "no allusion is made to any one of these things;" and then he qualifies the statement by adding "so far as we can see." The article is written with a view to condemn experimental and "morbid research," and if its facts had some approach to truth, we should not care to cavil at the writer's views. But anyone reading the article in question will hardly credit the fact that in a volume of 526 pages, only the last 60 are given to matters of scientific pathology and cultural experiments such as are referred to. Neither would they believe that the remaining 467 pages are almost exclusively given up to the administration of the vaccination law, to lengthened accounts of epidemics of typhoid fever, to the dangerous pollution of rivers with sewage and specific excreta, to diphtheria, to the obscure epidemic of skin disease which has been so prevalent and fatal in some of our workhouses, to the conditions associated with lead poisoning of moorland waters, to cholera at home and abroad, and to the question of quarantine as affecting our relations with foreign countries. And yet this is the fact. Indeed, it becomes difficult to understand how far the writer did see the volume which he reviews "so far as" he "can see." Then he complains that all was so different in the days of Sir John Simon, whose reports on local conditions showed a "fine crusading spirit abroad;" but he seems ignorant of the fact that this crusading spirit has, with increase of staff, so enormously extended since Sir John Simon's days that the parallel reports are now issued separately, and that the annual volume, which could no longer contain them, only gives an abstract of documents which have already been

printed and issued both locally and to the public. This abstract alone covers many pages; indeed, we would advise the writer to look at the volume again in a somewhat less superficial manner, and however much he may object to experimental research, he will find that the report contains evidence of more administrative and practical public health work than is performed or recorded by any other public health department in the world.

WELL-VACCINATED LOCALITIES.

In the frequent and often amazingly imbecile discussions which occur now at Boards of Guardians where antivaccinationists prevail, a sort of commonplace formula appears to be generally employed which satisfies the guardian intellect. It is that small-pox outbreaks are most frequent in what are described as "well-vaccinated localities." Of course there is no such thing as vaccinating a locality, but what is probably meant in localities in which there is a good deal of vaccination, or in which vaccination is not altogether in abeyance. Even in this form the statement is untrue, and for the most part deliberately fraudulent. The towns which have suffered most from small-pox epidemics are those in what is known as the heavy woollen districts, Bradford, Keighley, Dewsbury, Leicester, etc., where vaccination has been most neglected. Marylebone is pointed to as a well-vaccinated district in which small-pox epidemics have occurred, but it is precisely in the parts of Marylebone where the population is well vaccinated that small-pox was least prevalent, and there, as everywhere else, it was the unvaccinated population who had not been revaccinated after attaining adult age, which suffered from small-pox deaths. We need not recapitulate the figures in detail, for they tell the same story as everywhere else, but we may point to two examples in illustration: Thus, between May, 1892, and March, 1893, Warrington, with a population of 54,000, had 598 cases of small-pox, with 60 deaths; 57 of them were under 10 years of age, and of these 24 were vaccinated, of whom none died; 32 were unvaccinated, of whom 13, or 40.6 per cent., died; 1 case was doubtful. Of those over 10 years of age, however, 506 were vaccinated, of whom 32 died, a case-mortality of 6.3 per cent., while of the 34 who were unvaccinated, 13, or 38.2 per cent., died. Glasgow, again, tells the same tale. In 1892-93 there were 10 cases of small-pox in patients under 10 years of age who had been vaccinated; of these none died; and 2 who had not been vaccinated, both of whom died. Of the cases over 10 years of age, 238 had been vaccinated, and of these 11, or 4.6 per cent., died; while 9 were unvaccinated, of whom 5, or 55.5 per cent., died. The lesson is uniform and the deductions in favour of vaccination inevitable, and only those who are densely obtuse or prejudiced can fail to read the moral. Unhappily the majority of the antivaccinationists are either one or the other, or frequently both. They are impervious to facts, figures, or to reason. The scandalous dishonesty of the papers which give unlimited space to the utterly false statements of the antivaccinationists and deliberately and incessantly refuse publication of the facts proving the enormous efficacy of vaccination against small-pox is largely responsible for criminal concealment of the true facts and the diffusion of this death-dealing delusion to which some of the conductors of these papers are firmly wedded. Whatever their opinions may be, it is in the highest degree dishonest and dangerous to suppress, as they habitually do, the facts which from week to week come to hand proving the life-saving powers of vaccination. Papers like the *Star* and the *Bevo* are largely responsible for the small-pox deaths which are occurring on so many sides, and for the expenditure of money and life due to these entirely preventable local epidemics.

THE Chair of Pathology in the Faculty of the Jefferson Medical College in Philadelphia is vacant.

INOCULATIONS AGAINST CHOLERA IN INDIA.

REPORT OF DR. HAFKINE'S RESULTS UP TO DATE.

FROM a report to the Corporation of Calcutta made by Dr. W. J. Simpson, the health officer of the city, on August 18th, we obtain the following interesting statement of results of the Hafkine inoculations against cholera up to the present date. Dr. Simpson reports:—

Now that a year has passed since the Commissioners granted the sum of Rs. 7,500 for the purpose of carrying on anti-choleraic inoculations in Calcutta he has the honour to submit a report on the work done and also a summary of the results obtained, not only in Calcutta, but in other parts of India in the period in which these inoculations have been practised in this country.

In the note which he had the honour of presenting to the Commissioners in May of last year, recommending an extended trial of Professor Hafkine's system in Calcutta, he brought particularly to the attention of the Commissioners the remarkably favourable results which had followed this system in the case of Katal Bagan Bustee. The events connected with Katal Bagan Bustee will be still fresh in the minds of the Commissioners, for they produced a deep impression on all who were interested in the prevention of cholera. A group of people, living under similar conditions in a bustee with cholera among them, were subjected to an experimental test. The test, which was of peculiar importance as it marked an advance on the laboratory experiences, consisted in the inoculation of 116 persons out of a localised group of 200, among whom 2 fatal cases of cholera and 2 cases of diarrhoea had already occurred, and in comparing the liability of the inoculated and uninoculated to the prevailing disease. The continuance of the disease in the bustee permitted of this comparison, and it was found that no cases occurred subsequently among the inoculated, whereas 10 cases, of which 7 proved fatal, occurred among the not inoculated.

From the time the Hafkine system was first introduced into Calcutta till July 15th, 1895, 4,397 persons have been inoculated, which is more than double the number of vaccinations performed annually in this city twenty-five years after vaccination against small-pox had been introduced. Of the 4,397 persons inoculated, 1,060 were Mohammedans, 25 Europeans, 10 Eurasians, and 3,302 Hindus, including 363 Brahmans. The following statement gives further details:

Hindus.					Mohammedans					Other Classes					Grand Total.
Adults.		Children under 12 Years.			Adults.		Children under 12 Years.			Adults.		Children under 12 Years.			
M.	F.	M.	F.	Total.	M.	F.	M.	F.	Total.	M.	F.	M.	F.	Total.	
1,693	660	720	440	3,513	546	29	302	217	1,094	20	6	5	2	33	4,397

The number would undoubtedly have been greater and the observations which follow probably more numerous had not the events connected with the Lucknow outbreak in the East Lancashire Regiment lessened public confidence in the efficacy of the prophylactic. This decline in public estimation was mainly due to the manner in which the facts relating to the Lucknow epidemic were distorted, and to the virulent attacks by ignorant people on the inoculations, which were stigmatised as being everything that was evil, and the source of the most heathen diseases and of every ill to which man is heir. The distrust engendered by these misrepresentations and fulminations was, however, only of a temporary nature, and when the exact circumstances con-

nected with the Lucknow outbreak came to be known and understood, and it was seen that the inoculated had in reality suffered less and had fewer deaths proportionately than the not inoculated, the confidence created by the Calcutta experience began to be considerably restored.

The observations made during the period under record may be divided into those of a negative and positive character. Of the negative kind it has several times been observed that, when the inoculations were introduced into an infected locality, the cholera ceased in the course of a few days; it has also been noticed that in some localities notorious for their recurring cholera, and where on account of this large numbers have been inoculated, cholera has during the year been particularly absent. In the case of a small bustee in which the people petitioned to be inoculated because they were constantly suffering from cholera, not a single case has occurred since the inoculations last year.

Evidence of a more convincing and more direct nature exists, however, in the observations of a positive kind collected during the period under review.

Opportunities for comparing the liability to cholera of inoculated with uninoculated living under similar conditions in the same houses presented themselves no fewer than thirty-six times—once in Seebpore across the river and thirty-five times in Calcutta. These opportunities arise from the circumstance that cholera during its season will, sooner or later, appear in some of the huts in the bustees of Calcutta. When this happens in huts in which no previous inoculations have been performed no materials for an observation are forthcoming; but when it happens in huts in which some of the inmates have been inoculated and the others have not the essentials necessary for observation and comparison are existent. There were thirty-six such occurrences in thirty-six houses, and they are of the utmost importance, for they furnish 36 observations, separate both in time and locality, and they allow of conclusions being drawn regarding the value of the inoculations. In the 36 houses the total number of inmates was 521; of this number, 181 were inoculated and 340 not inoculated. The uninoculated members of these houses had altogether 45 cases with 39 deaths; the inoculated had 4 fatal cases, of which one occurred 459 days after the first inoculation in a child who had not been brought for the second inoculation; and the 3 others from one to four days after the first inoculation before the protective influence of the vaccine had time to assert itself, and therefore before the second vaccine could be applied. Including all cases without reference to their occurrence in time, the percentages were as follows:

338¹ uninoculated 45 cases (13.48 per cent.) 35 deaths (11.64 per cent.)
181 inoculated 4 cases (2.21 per cent.) 4 deaths (2.21 per cent.)

The difference in these figures shows that the not inoculated were 6.08 times more liable to attack, and 5.97 times more liable to death from cholera than the inoculated.

Analysis of the figures and classification of the occurrences according to time demonstrate the results to be even more strikingly favourable. It will be borne in mind that there is in the treatment two injections, one five days later than the other; the first is made with the weak vaccine, and requires five days for its full protection, and the other with the stronger vaccine, which requires another five days to secure complete action; a similar period of eight or nine days is necessary for the full protective power of vaccine against small-pox.

The figures are as follows:

During the First Five Days.

	Average Number Present at time of Attack.	Cases.	Per cent.	Deaths.	Per cent.
Not inoculated	25	6	2.40	6	2.40
Inoculated	20	2	1.11	2	1.11

¹ Deaths from cholera at the time of the observations reduced the original number of the uninoculated to an average of 25.

After Eight Days.

	Average Number Present at Date of Attack.	Cases.	Per Cent.	Deaths.	Per Cent.
Not inoculated ...	263	39	14.72	35	15.21
Inoculated ...	140	1	0.71	1	0.71

The above figures show that during the first eight days before the vaccinee have time to protect the system, the inoculated and not inoculated present a similar liability. This similar liability disappears after the first vaccinee has been in the system for five days, the three deaths among the inoculated occurring previous to the fifth day. After eight days, and in fact after five days, the difference in liability to attack becomes very marked, the inoculated living in the same houses in Calcutta being twenty times safer from attack and eighteen times securer from death than the not inoculated should cholera enter the house. This is protection of a very decided character. Further, the single death among the inoculated was 459 days after the inoculation in a child who had not undergone the full treatment, that is, she had only been inoculated with the weak vaccine. No case of cholera occurred among those who subjected themselves to both inoculations.

There are some very remarkable cases, and he would invite the special attention of the Commissioners to four of these. They are cases in which the proportion of inoculated living in the house or room was much larger than that of the not inoculated, and yet when cholera appeared it picked out the not inoculated, leaving the inoculated free. They are the houses marked on the list 3, 8, 16, and 36.

In No. 3, which is Isco Mistry's house Begbagan, 4 persons out of 6 were inoculated in March, 1894, and fatal cholera appeared in the house in June of the same year, and selected for attack one of the two not inoculated, the 4 inoculated remaining free of the disease.

In No. 8 on the list, which is Ramdhone Dutt's house at Katabagan Bastea, 6 persons out of 8 were inoculated in March, 1894, and fatal cholera entered the house in the following April, and attacked one of the two not inoculated, leaving the 6 inoculated unaffected.

In No. 16, which is Gonessee Bewah's house at 16, Jorabagan Street, 4 persons out of 5 living together in one room were inoculated in May, 1894, and fatal cholera showed itself in the room in the next July, and attacked the only one not inoculated, the 4 inoculated keeping quite healthy.

In No. 36, which is the house of Baboo Banikanta Mookerjee, Kalikumar Mookerjee's Lane, Shibpore, 6 members of a family of 7 were inoculated in July, 1894. In March of 1895 the only one not inoculated was affected with cholera and died, the inoculated remaining quite well.

Were there no other instances than these 4, he would feel justified in recommending the Commissioners to continue the cholera grant, but with the list which he had presented he had no hesitation in saying that it was his duty to do so in order that the benefits of the inoculations may be brought within the reach of the poorer inhabitants of Calcutta, and of all those even of the better class who may desire to be inoculated. That cholera is no respecter of persons in the endemic area even under conditions which appear to be satisfactory in their sanitary aspects, the sad death of Sir Henry Harrison, the late highly respected Chairman of the Municipality, and the more recent death of Brigade-Surgeon-Lieutenant Colonel Coates, the former Principal of Calcutta Medical College, are instances which will recall themselves to everyone in Calcutta.

The grant was asked for last year as an experiment; now it is asked as a means of affording protection against cholera to those inhabitants of Calcutta who may wish to avail themselves of the measure. In doing this he would place before the Commissioners the observations corroborative of the efficacy of the inoculation which have been obtained independently in other parts of India, and which, together with those in Calcutta, form such a mass of evidence in their favour as to remove all objections based on preconceived opinions, imaginary theories, or prejudice.

In his last memorandum on the subject, dated October 1st, Dr. Simpson recorded the cases at Gya, Cawnpore, Dinapore, and Lucknow, and he recapitulates the principal facts connected with these observations.

At the Gya Gaoi inoculations were performed during the progress of an epidemic and after 6 cases and 5 deaths had occurred. Half the prisoners were inoculated, the remainder being left not inoculated. The incidence of the disease on the two groups was as follows:

	Not Inoculated.		Inoculated.	
	Cases.	Deaths.	Cases.	Deaths.
During first 5 days after second inoculation ...	7	5	5	4
During 3 days after second inoculation ...	5	3	3	1
After 5 days from first inoculation ...	8	2	—	—
Total ...	20	10	8	5

It will be observed from this statement that there was a gradual diminution of cases and deaths among the inoculated, and after eight days there were no cases or deaths among the inoculated, while there were among the not inoculated 8 cases and 2 deaths. It is further to be noted that the mortality among the not inoculated was twice that among the inoculated. In connection with this reduction of mortality it may be stated that the antitoxin treatment of diphtheria, which has caused a commotion throughout the civilized world, does not reduce the mortality from diphtheria more than that secured by the anticholeraic inoculations applied at the time of an epidemic of cholera in the Gya Gaoi.

In Cawnpore, when cholera broke out among the troops 13 months after the inoculations, the results were:

	Numbers.	Cases.	Per cent.	Deaths.	Per cent.
Uninoculated ...	797	13	2.38	13	1.63
Inoculated ...	75	—	—	—	—

At Dinapore, in the Manchester Regiment the inoculations were applied during an epidemic after 13 cases and 9 deaths occurred, with the following result:

	Numbers.	Cases.	Per cent.	Deaths.	Per cent.
Uninoculated ...	729	6	0.82	3	0.41
Inoculated ...	134	—	—	—	—

In Lucknow, in the East Lancashire Regiment, a part of which had been inoculated fourteen to fifteen months previously, cholera broke out in July, 1894, with the following result:

	Number Present.	No. of Attacks.	Percent of Strength.	No. of Deaths.	Percent of Strength.
Not inoculated..	640	120	18.75	79	12.34
Inoculated ..	133	16	12.03	13	9.77

This table shows only a small proportion in favour of the inoculation, probably due, as was explained at the time, to the weakness of the vaccine used, and the effect still further lessened by the lapse of time.

To these observations he had now added those recently collected by the medical officers and managers of the Assam Tea Gardens, and which had been kindly given him by M. Haffkine. They confirm the general results obtained elsewhere as to the protective influence of the inoculations.

	Cases.	Per Cent.	Deaths.	Per Cent.
Uninoculated:				
On the whole garden, 1,130 ...	2	0.17	2	0.17
In the affected lines, 70 ...	2	2.86	2	2.86
In the affected houses, 7 ...	2	28.57	2	28.57
Inoculated:				
On the whole garden, 441 ...	None	—	None	—
In the affected lines, 63 ...	1	1.59	1	1.59
In the affected houses, 1 ...	1	100	1	100

OBSERVATIONS IN THE DEGUBBER TEA GARDEN, KALAIN P. O.
(Collected by Dr. A. Powell, Medical Officer, and Mr. H. Chamney, Manager.)

There were 2 cases in Degubber; 1 fatal. Both cases occurred in uninoculated coolies. The percentages of the occurrences were as follows:

	Cases.	Per Cent.	Deaths.	Per Cent.
Uninoculated:				
On the whole garden, 299 ...	2	0.67	1	0.44
In the affected lines, 64 ...	2	3.12	1	1.56
In the affected houses, 5 ...	2	40	1	20
Inoculated:				
On the whole garden, 302 ...	None	—	None	—
In the affected lines, 62 ...	1	1.61	1	1.61
In the affected houses, 3 ...	1	33.33	1	33.33

OBSERVATIONS IN THE ADAM TILA TEA GARDEN, CHANDKHIRA P. O.

(Collected by Mr. H. A. Brown Constable, Manager.)

Two cases with 1 death are reported from Adam Tila, both in people inoculated once, two and two and a-half months after inoculation. The percentages of occurrences are:

	Cases.	Per Cent.	Deaths.	Per Cent.
Uninoculated:				
On the whole garden, 657 ...	None	—	None	—
In the affected lines, 1 ...	1	100	1	100
In the affected houses, 4 ...	1	25	1	25
Inoculated:				
On the whole garden, 31 ...	2*	6.45	1	3.23
In the affected lines, 3 ...	2*	66.67	1	33.33
In the affected houses, 2 ...	2*	100	1	50

* Inoculated once.

CASES IN THE BURNIE BRAES (HALLIKANDI P. O.), LOOBACHERA (ATGRAM P. O.), KALAINCHERA (KALAIN P. O.), AND SANDURA (KALAIN P. O.) TEA GARDENS.

No returns have been as yet received from these gardens further than a communication that, since the date of the inoculation, there occurred 2 cases with 1 death in the Burnie Braes, 3 cases with 1 death in Loobachera, 4 cases with 2 deaths in Kalainchera, and 2 cases with 1 death in Sandura, all in uninoculated coolies. Of these gardens in Burnie Braes and in Kalainchera a large proportion of the population had been inoculated (449 and 145 respectively, making one-fourth to one-half of the whole population); in the 2 other gardens the proportion of inoculated was from $\frac{1}{2}$ to $\frac{1}{3}$ of the total.

Summarising the observations made on the gardens on coolies inoculated once, that is, before the second inoculation was applied, the results are as follows:

Total of Uninoculated on all the Affected Gardens.*

	Cases.	Per Cent.	Deaths.	Per Cent.
In the whole population, 5,222 ...	38	0.73	19	0.36
In the affected lines, 509 ...	38	16.16	19	5.05
In the affected houses, 95 ...	38	40.00	19	20.00

* Exclusive of the 19 cases with 11 deaths in now uninoculated coolies, and 11 cases with 5 deaths in old uninoculated coolies, but regarding which the returns have not yet arrived.

Total of Inoculated on all the Affected Gardens.

	Cases.	Per Cent.	Deaths.	Per Cent.
In the whole population, 2,741 ...	5	0.18	3	0.11
In the affected lines, 369 ...	5	1.36	3	0.80
In the affected houses, 60 ...	5	12.50	3	7.50

To this information Dr. Simpson has added that contained in two letters addressed to him recently by two influential mercantile firms in Calcutta, in whose gardens inoculations have been carried out. They are additional observations to those already mentioned, and improve the results given by M. Haflkine to a considerable extent.

TO HEALTH OFFICER.

We have pleasure in communicating the under-noted extract from a letter from Mr. H. Weir, Manager of Kalline Tea Estate, Cachar, dated 3rd instant, on subject of Dr. Haflkine's experiments in inoculation for cholera.

Calcutta, 15th July, 1895. MACNELL AND CO.
Our results here since I last wrote you on the subject are all most favourable. As regards inoculation I mean, we have had 4 cases in all. No. 1 died had not been inoculated; 5 other people in his house had been, and escaped any attack.

No. 2 recovered; had not been inoculated.
" 3 died " " " "
" 4 " " " "

I hope Dr. Simpson will be successful in getting the Municipal Commissioners to give a decent grant to try Dr. Haflkine's system properly. We have a very elaborate and complete register we keep for the professor here. The Professor took enormous pains and trouble, working far into the night examining every tube microscopically, and this for week after week, so it was only fair to do what we could in return; again only by careful comparison and record of inoculated households versus non-inoculated, and households in which half were inoculated and half not inoculated could we fairly test his system. The professor is a gentleman of most charming and gentle manner, and it is quite a pleasure to me to be able to do him any slight service. His work is exceedingly laborious, and it must be a great strain, besides involving a very heavy expenditure from his private fortune. No one who has met the professor can fail to wish success to both the cause (science versus disease) and the man.

We have received from the local Manager of the North-Western Cachar Tea Company a statistical statement of the results of Professor Haflkine's cholera inoculation on the Company's estates. As we believe this statement to be of value to you, we have pleasure in herewith submitting a copy.

Calcutta, July 24th, 1895. DUNCAN BROTHERS AND CO.

At Degubber we had 5 cases of cholera, 2 of which were inoculated and both recovered; the 3 uninoculated cases all died.

* At Kurkoorie we had 16 cases; uninoculated 14, of which 11 died and 3 recovered, one case twice inoculated recovered, the other case only received the first inoculation and died, but there is some doubt if death was not caused as much by a long attack of dysentery.

Kurkoorie Tea Estate, July 14th, 1895. H. CHAMNEY.

These letters indicate the interest that is being taken in the subject, while their contents furnish strong proof of the value of the inoculations.

At the Indian Medical Congress, when the observations of Assam had not been made, and when the observations in Calcutta were only 13 instead of 86 as now, the medical profession received the results with much favour, and were unanimously of opinion that the inoculations should be tried on as extensive a scale as possible. More recently, at a largely attended meeting of the Calcutta Medical Society, when similar figures to those now brought to the notice of the Commissioners were laid before the members, they were so impressed with their value that they unanimously passed a resolution that the inoculation ought to be continued.

With this report before them Dr. Simpson trusts the Commissioners will not hesitate to sanction a grant of Rs. 10,000. This sum is needed to place the inoculations on a satisfactory basis. By securing more than one trained vaccinator, the inoculations can be spread with greater facilities, and much can be done which it was impossible to do this year owing to a very limited establishment. By granting facilities to carry out this important work in the capital of India, which is regarded as the centre of "the home of cholera," and the city of all others in the East to which Governments turn for information concerning this disease, as indicated in the

* At Kurkoorie over 400 were inoculated, and only 200 left uninoculated.

scientific missions of Koch from Germany, Klein from England, Zahn from Geneva, and Shakespere from America, the Commissioners will not only be conferring a public benefit on the inhabitants of Calcutta who are so subject to cholera, but they will also be leading the way to the introduction of a prophylactic measure, which, either in its present or in a modified form, may be expected to effect an enormous reduction in the ravages of cholera among Eastern and Western populations.

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.¹

[FIRST NOTICE.]

The report of the Medical Officer of the Local Government Board for the year 1892-93 fully maintains the interesting characters of the series of which it forms part, and is indeed a valuable contribution to the State literature on waterborne typhoid fever, a subject treated at some length by Dr. Thorne in his introduction.

VACCINATION.

Dr. Thorne has nothing good to say concerning the state of vaccination as regards the children born in 1891, the latest year for which returns are in a condition for publication. The percentage of infants not finally accounted for in respect of their vaccination was 13.4, the greatest increase in default of recent years having set in during 1889, the year in which the Royal Commission on Vaccination was appointed. In the metropolis the default in 1881 was only 5.7, and has continuously increased, until ten years later it was 16.4, as against 12.9 in the provinces, the proportions being higher than during any of the preceding twenty years. Thus is stationary, and indeed all vaccination, falling off in England, and an ever-swelling number of unvaccinated persons growing up to increase the small-pox death-rates of coming years.

INUSCEPTIBILITY TO VACCINATION.

Dr. Thorne very properly looks with sceptical eye on the so-called "in susceptibility" to vaccination which finds so large a place in the returns from time to time. He proceeds to show that out of 81,500 persons submitted to vaccination at the hands of vaccinators connected with the Board's Vaccine Department during a series of years not a single case of "in susceptibility" has been chronicled; whilst, on the other hand, of 98,871 children submitted to the operator's lancet in London in 1891 alone, 432 were certified to be "in susceptible." The comparison is striking and instructive.

WATERBORNE TYPHOID FEVER.

The inquiries undertaken by the Medical Department during the year under review, and which had for their object the tracing out of the causation of epidemics of enteric fever, as the result proved, to the agency of polluted public water supplies, were both numerous and interesting. Dr. Thorne passes under review the principal reports made to the Department, and in this way places on record an instructive summary account of the epidemics at Worthing, Chester-le-Street, Ryedale, and Malton, and in certain Trentside villages. As these have already been the subject of comment in the *BRITISH MEDICAL JOURNAL*, we need say nothing more concerning them here. Neither need we refer again to Dr. Copeman's reports on epidemic skin disease, which are reproduced *in extenso*, with some summary remarks by Dr. Thorne.

NOTIFICATION RETURNS.

We are glad to see these returns claiming an increased amount of attention and space in the report, and the year 1892 contributes not only the returns in respect of 81 sanitary districts (London being a unit) quarter by quarter, and for the year, in respect of small-pox, scarlet fever, and diphtheria, and the several "fevers," but also weekly, quarterly, and annual returns for each sanitary area in Lon-

don, the deaths too being given. The data thus collated will become more and more valuable as time goes on; and we trust they are but the beginnings of larger things.

LEAD POISONING BY MOORLAND WATERS.

Mr. W. H. Power's forecast of 1887 as to the relation of the plumbo-solvent ability of moorland waters to the agency, direct or indirect, of low forms of organic life, finds confirmation in the doings of the year 1892-93, the experiments conducted with samples of one and another moorland water, showing that variations in the lead dissolving properties of a water were always associated with corresponding variations in the amount of its acid; further, that the addition to either moorland water or a sterile decoction of peat of a minimal amount of moist peat soil will cause bacterial growth, with increasing development of acid reaction and plumbo-solvent ability; and in addition that there are only two species of microbes found in peat which have the power of producing acidity when added to a sterile decoction of peat. Mr. Power's report on the progress thus far made, and voluminous data in addenda, are included in the volume.

CHOLERA.

Dr. Barry contributes a short report on three prevalences of cholera in Germany which may be regarded as belonging to the 1892 series, namely, at Hamburg, 1892-93, with 64 attacks and 17 deaths; at Altona, with 45 attacks and 24 deaths; and at the Nettleben Lunatic Asylum, with 122 attacks and 52 deaths in a community of 991 persons. For the rest, a short account is given of some other occurrences in Europe; but the next annual volume is to contain in detail the history of European cholera prevalences in 1893. We are told that the results of the elaborate cholera survey of the coast are to furnish a further volume by themselves, and one that will doubtless afford much valuable information. The steps which led to the present attitude of the State towards *ragu quid* cholera are set out by Dr. Thorne in his account of the proceedings of the International Sanitary Conference at Dresden in 1893. The English practice is now that which was formally adopted in the Convention signed as the outcome of the Conference.

THE BLESSINGS OF VACCINATION.

DR. CHARLES STEELE, of Clifton, writes to us:

I was lately conversing with my friend Canon Kissack in his rectory at Ballaugh, and he read to me several interesting facts from the old church register which he had carefully copied. Amongst others these items, which I took down at the time, as they show what an immense blessing vaccination has been, and I hope that you may like to insert them as a record of this fact:

Parish Register, Ballaugh Church, Isle of Man.

Date.	Deaths.		
	Small-pox.	Other Causes.	Total.

PRESENTATION.—The Mayor of Bangor, Alderman R. Langford Jones, M.R.C.S., has been presented by the police of the Bangor division with a silver-mounted mace and ivory walking stick as a memento of the services rendered by him as lecturer to a successful ambulance class of police officers during last winter. The presentation was made by Lieutenant-Colonel Ruck, chief constable of the county, who at the same time distributed to the members of the class present the certificates of the St. John Ambulance Association. The presentation bears the following inscription: "Presented by the City Police to the Mayor of Bangor, 1893."

¹ Report of the Medical Officer of the Local Government Board for 1892-93. Sold by Messrs. Eyre and Spottiswoode, East Harding Street, London; Messrs. Menzies and Co., Edinburgh and Glasgow; and Messrs. Hodges, Figgis, and Co., Grafton Street, Dublin. (Pp. 200. 1893. 6d.)

REPORTS

ON

THE NURSING AND ADMINISTRATION
OF IRISH WORKHOUSES
AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

INTRODUCTION.

THE condition of the Irish workhouses is attracting much attention at the present time, and the action of the Irish Medical Association, which has approached the Local Government Board on this matter, has brought the question to a focus. In the circular issued by that body, the Association requests the Local Government Board to inquire into the truth of the charges of mismanagement, insufficient nursing and neglect, which have come under its cognisance through the action of certain members of the profession, themselves medical officers of the various unions all over the country.

Dr. Moorhead, a Poor Law medical officer, incited thereto by reading the reports on the English workhouses published in the *BRITISH MEDICAL JOURNAL*, addressed a letter to his colleagues asking for information concerning the conditions under which the poor were treated in the hospitals under their care. The answers which were received induced him to seek for more definite information in the form of replies to queries relating to structure, sanitary appliances, domestic furniture, and the care of the idiots. Answers were received from 79 doctors. The whole of this correspondence was treated as confidential, but on the basis of the facts thus collected, Dr. Moorhead read a paper before the Irish Medical Association in January of this year on the condition of the Irish workhouses. The result of these inquiries showed that the union medical officers were fully alive to the state of affairs in the hospitals under their care, but were powerless to bring about any material improvement in the condition of the sick pauper. A tabulated statement of the answers showed that in all cases the nursing was insufficient in quantity and quality, and that it was practically in the hands of the paupers; in 36 infirmaries the proportion of trained nurses was as one nurse to 36.2 patients; 43 infirmaries, having a population of 2,694 sick, have no trained nurses; sanitary appliances are almost non-existent, 59 infirmaries having privies or pails; in 50 no water is laid on; in 47 there are no cooking stoves; in 61 the idiots are in the charge of pauper inmates; and structural shortcomings are very evident.

Wishing on our own part to ascertain in detail the condition of the Irish workhouses, we sent our Commissioner to visit and report on the actual state of the case; and from the reports made on 28 houses selected from all parts of the country, we are of opinion that the case of the Irish Medical Association has been proved up to the hilt. Indeed there is one of the subjects—the circumstances surrounding the aged paupers in the body of the house—which has hardly received the attention that it deserves. Their condition has come out in almost darker colours than that of the sick.

To make the subject clear to our readers, we would refer them to the accompanying view and plan of a workhouse,¹ premising that the ground plan of the country workhouses is, with very few exceptions, invariable, and that the distribution or classification of the inmates is the same, even when the structure is slightly different. We have then the three sections, the lodge or entrance, the body of the house, and the hospital or infirmary. To this plan the fever hospital,

standing in the grounds, has been more recently added, sometimes behind the hospital, sometimes to the side of it. The Irish workhouses in this respect differ from those in England. The hospital, forming part of the original plan, was built at the same time—1839 to 1842—as the rest, so that the doctor carries on his work in buildings and with appliances fifty years behind the times. The English sick pauper, on the contrary, has only recently been treated apart from the able-bodied, hence the infirmaries are of more modern construction.

The plan of the Irish workhouse, as the sketch shows, was drawn at a period in the history of the country when the able-bodied quite outnumbered the sick and infirm; the result is that the sick quarters are now overcrowded, that certain infirm patients are kept in the infirm wards who would fare better in the hospital, and that the large space allotted to the able-bodied is half empty. The aged and infirm are placed in the two wings of the central block, and occupy the ground floor, unless, as some of the reports show, they have overflowed upstairs; they are there at some distance from the officers' quarters in the middle of the block, and separated from them by the intervening portions of the children's dormitories or schoolrooms. When these wards are locked on the outside at 7 p.m. the inmates are left with only such help as they can render each other, and the only conveniences for the eleven or more hours of their imprisonment are the open pails and buckets, which remain unemptied until the morning. When to this we add that these wards are frequently without any light during the night, it will be seen how it is possible for the old people to fall out of their narrow beds, or even to be found dead on the floor, as has been asserted by credible witnesses.

In the various comments made on the circular of the Irish Medical Association, either by the guardians or by the public press, this point has been overlooked, and yet it is our opinion that it is one which calls for immediate attention. Until it is remedied it reflects great discredit on the authorities who are responsible for its continuance.

The reports which lie before us are sad reading, and reveal a condition of things which our readers will scarcely credit as existing in the nineteenth century. The surroundings of the idiots and the infirm sound more like a chapter in the history of a Siberian exile, the notes of a visit to an *etep*, than the matter of fact statement of sights seen in a workhouse in this kingdom. The poor old people lie untended through the long hours of the night on their narrow wooden frames and straw ticks, being locked up in the dark to breathe an atmosphere fouled with excremental emanations, the mud or brick floor at times the receptacle of the dejections. The aggregate which this picture presents of human misery and suffering is hard to realise. Once they enter this house they can only go out by taking their discharge; each class takes exercise in its own yard (the size of that attached to the infirmary can be seen on the plan), but the leave day for the well-conducted, according to our English custom is unknown in Ireland. When we add that our Commissioner saw in some houses the hapless idiots kept in cells that differ in no way from those of a prison—cells condemned by Lord Shaftesbury in 1843 as being architecturally unfit for occupation by this class—we feel that it is quite time to arouse the country to a state of righteous indignation over their treatment.

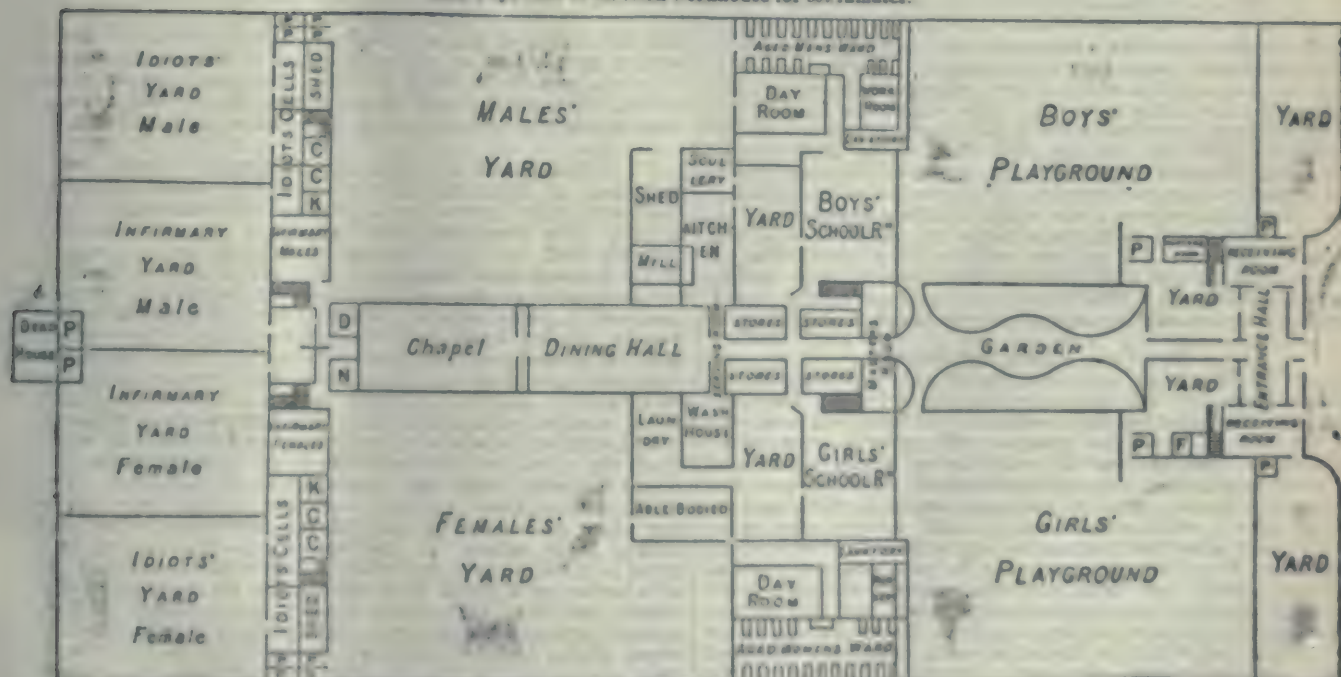

The nursing of the sick is complicated by the religious difficulty. We are aware that it must be faced, and we trust that the Local Government Board will handle the matter with decision. In many of the unions the sick wards are nursed by the nuns. The fullest justice is done by our Commissioner to the excellent work of these devoted ladies; but they are hampered by certain restrictions which limit their usefulness and must tend to invalidate the treatment of the medical officer; we refer to their lack of hospital training, to their difficulty with some of the male patients, and to their non-performance of night duty. It is certain that until trained nurses, whether nuns or otherwise, are appointed, and in sufficient numbers to supersede the pauper help, the public conscience cannot be satisfied.

In appointing the trained nurse the Local Government Board will be asked to define her position. She does not exist in the General Orders; she has not even the modest

¹ Copied by kind permission of the authorities of the British Museum.

Bird's eye view of an Irish workhouse for 500 inmates.

Ground plan of an Irish workhouse for 500 inmates.

Three paragraphs in which the English General Orders recognise her existence; if referred to incidentally, it is as an assistant to the matron. When the General Orders were framed there were no trained nurses, but now their necessity is recognised and their omission should be supplied.

It is evident from the foregoing remarks that the Local

Government Board has a hard task before it—no less than bringing the Poor Law into harmony with the spirit of the times. There are stubborn inelastic structures to deal with, buildings that were constructed in accordance with social requirements that have passed never to return; prejudices and traditions to fight, which will die hard; local poverty to

consider, which will resent additional burdens; a state of indifference about the welfare of the pauper, which it is hard to move. All these obstacles, and many others, lie in the path to reform; but we are convinced that when once the attention of the public is roused, it will be ready to run ahead of cautious officialism. We judge that much might be done with the existing machinery to ameliorate the condition of the pauper, giving a better class of officer armed with a wider discretion in dealing with the well-conducted and respectable class of pauper, and more humanity in the interpretation of the general orders.

Taking into consideration the circumstances of the country districts, we feel most strongly that the workhouse hospital should be the centre of medical relief for the neighbourhood, and that the sick should be encouraged to enter its walls. Thus many an illness might be successfully treated, and the chronic stage averted, which often throws the man and his family on the rates. But the independent labourer shrinks from the badge of the pauper, and from the sordid surroundings in which he finds himself; moreover, the tender mercies of the pauper nurse are cruel. It will be found the truest social economy to improve the equipment of the workhouse hospital, so that the sick of all classes who cannot be efficiently treated in their own homes may seek healing there.

There are many other matters treated incidentally in the reports on which we should like to touch: The construction of the fever hospitals and the decline of fever in the country; the absence of baths, and the antiquated condition of the domestic offices; the monotony and poor quality of the diets; the hardships of the Act of Settlement. But space fails us, and on these points we must let the reports speak for themselves; we feel sure that when we have laid the facts in our possession before the public, it will rise up and demand a revision of the Poor Law.

LIII.—BASINGSTOKE WORKHOUSE.

We found the workhouse situated about a mile and a-half from the town; it really stands in the parish of Basing, which at the time the workhouse was built was the town, Basingstoke not then being in existence. The union buildings stand on a hill having a fine view over the country; the ground-plan is in the form of a Latin cross, the head of the cross forming the entrance hall, the chapel and some of the wards being in the upright and other wards in the arms; the administrative block is in the centre of the cross where the arms intersect the upright. The exterior of the building has a forbidding aspect; the small windows, sparsely placed in the high brick walls, were more suggestive of a prison than a workhouse; it was not until we were inside that we noticed that a few sash windows had been broken out in some of the rooms. The master and matron kindly placed their services at our disposal to take us round the building.

THE SICK, AGED, AND INFIRM

are to be found all over the workhouse, for there is no infirmary proper, but certain wards are set apart for their use. The number on the medical relief book was low, due to the time of year—the summer: 60 patients were under treatment, 17 females and 21 males being in the wards, and of these about half were confined to bed. The bulk of the cases were chronic, such as old age, paralysis, blindness; a male patient with carbuncles, a most severe case, now recovering; abscesses; injury to leg by the wheel of a cart, leg placed in splints, and reported to be doing well; rheumatism; small boy with phthisis; ulcerated legs; heart disease; besides these we saw several infirm men and women who were able to be up during the day. Many of these latter were occupied with the Brabazon work; one man crippled with rheumatic gout was most expert in the use of his fingers and had some good specimens of needlework to show.

THE WARDS

are located on the ground, first, and second floors. On the female side we found some of the able-bodied women on the first floor, the infirm wards being beneath and above; on the men's side some of the wards are on the ground floor, the able-bodied occupying the two storeys above, and other

wards above the chapel were assigned to the male infirm. We were shown a large empty ward holding 15 beds used by infirm men in the winter; indeed we were informed that the officers are at their wits' end to find accommodation for this class in the winter, and that they have to be placed anywhere. The wards structurally are most unsuitable for sick wards; they are low pitched (8 feet), the small windows, placed near the cornice, opening on a pivot, and regulated by a toothed bar, are insufficient for light and air; the fireplaces, in most instances of an obsolete pattern, are placed in a corner, and do not suffice for heating; the master told us that with a modern grate the thermometer at the opposite end of the ward barely registered 60°. It was easy to picture to ourselves the condition of these wards in the winter when crowded with patients, the windows being shut to husband such heat as the fire gave off, with the emanations from the various vessels, unemptied until the morning, and from the bodies of the old people, the conditions for the treatment of the sick cannot be considered favourable. The wards varied in size, the largest occupied holding 10 beds and the smallest 5; the beds stood less than 2 feet apart, and between every pair was a commode or chair. We noticed a very few arm-chairs scattered among the wards; a long deal table and benches completed the furniture; indeed, the master said that it was no good asking for chairs or lockers as there was no space for them. The only dayroom is a small one on the top floor for the old women, so that there is no relief to the wards except that of the yards or garden, in many cases inaccessible to the infirm. The walls are brick surface painted, and a liberal supply of pictures relieves their monotony. The bedsteads are of ancient date, low iron frames and laths, over which is a cocoanut mat and a tick filled with oat straw, pillows of the same, and flock pillows. Water or air mattresses are supplied where required, and any other appliances on the doctor's request. There are two spring beds, one on the male and one on the female side; we should like to see many more. There are no wards for isolation, nor for the sick children, nor for purposes of restraint.

THE LYING-IN WARD

is a slice taken off one of the female wards; it has two beds, is very small, has no separate offices or any appliances for its work, and it is much too near the general ward, from which it is separated only by a slight partition. The average cases are five in the year. One of the nurses is a midwife.

THERE ARE TWO TRAINED NURSES BY DAY,

but none at night, the only service being such as may be rendered by the inmate in charge of the ward, he or she being in bed. The guardians have had a night nurse, but she has recently died, and her vacancy has not yet been advertised. She, poor soul, used to say she could get no rest, nor get out of the hearing of the patients, and when we saw the nurses' quarters, in one case sliced out of a ward, in another immediately off the ward, we were not surprised. The nursing must be carried on under great difficulties, for the wards are scattered, and there are so many stairs. Pauper nurses are employed in this house, most of those on the female side being women with illegitimate children; we saw one such with her infant in the ward, and wondered which was sacrificed; the infant in that close atmosphere or the patients who might interfere with the woman's care of her infant. The whole system is bad, and it is useless to endeavour to supply the place of nurses by multiplying inefficient helps, and calling them nurses. In the winter time the nursing staff must be far too small, especially as the matron said that the able-bodied were not in sufficient number for the work of the house, and that labour was hired in the laundry. It does seem to be a curious perversion of intellect to retain the services of the inmates in a department where they are worse than useless, and to hire labour in another department where their work would be of value.

IN SANITARY ARRANGEMENTS

the workhouse is quite behind the times; on each landing we found a space partitioned off where there was a small sink and hot and cold taps, an earth closet, and some pails; in no case were these places in a clean condition, they appeared to be the receptacle of litter and rubbish, and some

of the closets were insanitary. There is no water-closet in the building, nor are there any baths except a large movable bath, unwieldy to fill or empty. In the infectious block we saw a zinc bath, having a plug, but on inquiry we ascertained that the plug was not over a drain, and was, therefore, of no use. The only fixed baths were attached to the schoolrooms; all ward vessels, therefore, are carried out of doors to the outside closets. The hot water supply is of quite recent date; until it was put in all water was heated in kettles or the copper.

THE NURSERY

is on the ground floor, close by the matron's staircase; it is divided into sections by dwarf partitions, originally intended, so we were informed, for the married quarters; the result is a square room spoilt. The cubicles are very crowded, 3 or 4 infants in cots, and an inmate being allotted to each. The remainder of the room is the day nursery; here we found 5 infants and 2 women; they had come in from the yard, and were being washed before dinner. We noticed a basin of scalded milk on the table, and the matron assured us that she superintended their meals every day. There was a long trough in the room and a cold water tap, and that was all the apparatus for bathing that we saw. We were informed that a bath was brought in for their use. We did not observe any toys or amusements for these little ones, and certainly the nursery would be a dreary place in the winter, when the children could not go out of doors. The building is the same as that used in the wards, and those cots that we turned up were quite clean and sweet.

THE INFECTIOUS HOSPITAL

stands on rising ground, behind and very close to the main building. A row of chimneys belonging to some of the offices discharge themselves on a level with the ward windows; this alone, to our mind, would make this hospital quite unsuitable for occupation by the sick; another objection is that the most light and air is by the north aspect. We note these defects, because we read that there is a wish on the part of some of the Board to utilise this building for the sick wards. The arrangement of the building is six wards, each for 4 beds, on two floors; there is a kitchen, laundry, nurses' rooms, and disinfecting closet. This hospital used to be used for such cases of infectious disease as occurred among the inmates; but we understand that a conjoint scheme is in contemplation between the town authorities and the guardians for the treatment of such cases, and hence some of the Board are in favour of patching the sick department by making use of this block. We have noted the condition of the bath room, and we also noted that there was no convenience of any description inside the building.

THE KITCHEN

is in process of improvement; the antiquated coppers are to give place to a cooking apparatus heated by steam, and coincident with this we hear that the dietary is to be reconst. We saw the dinners which were being served at the time of our visit—roast mutton, potatoes, and long beans; it appeared to be well cooked, and we were pleased to see that very rare dish—green vegetables out of the workhouse garden. There is no provision for carrying the food; however carefully the plates may be warmed, the food must be chilled in its passage from the kitchen. We also noticed that some of the old people were scarcely able to masticate the meat; we would suggest that the food were minced for them, as the nurses cannot have time to feed the patients individually.

RECOMMENDATIONS.

It must be obvious to our readers that there is but one course open to the Board offering any solution of the difficulties with which they are confronted; that course is a new infirmary. This is the only hospital for the immediate neighbourhood with the exception of a small cottage hospital, and is therefore the centre of medical relief for the union, but we find an antiquated building, no appliances for the nursing of the sick, no sanitary system, no wards for the separation of offensive or troublesome patients, or for the children, who must be placed with the adults, no proper accommodation for the nursing staff; and, moreover, the present wards are so overcrowded as to make them dangerous both to the patients and those who nurse them. Cleanliness and efficiency are

not compatible with the state of the present wards, and we only wonder that any presentable work is accomplished by the nurses.

We would also suggest that an ambulance be provided for the removal of the sick; as matters now stand it is the duty of the relieving officer to bring the patients to the infirmary. That he naturally does in any vehicle of the neighbourhood. We were told that the man injured by the cart was brought in a cab, a step which might have converted a simple accident into a dangerous or fatal injury.

THE ST. GEORGE'S WORKHOUSE INQUIRY.

Once more the Local Government Board have shown their astonishing capacity for leniency—a leniency which we have no hesitation in affirming allows them to perform acts of grave and gross injustice to the poor. It will not be forgotten that, as we have already reported, the St. Saviour's Board of Guardians being dissatisfied with the conduct of the master of St. George's Workhouse, brought certain charges against him which became the subject of a Local Government Board inquiry. Mr. Lockwood, one of the inspectors, held the inquiry, and Mr. Thompson, the master, whose actions were called in question, was suspended from his office pending the decision of the Local Government Board. The allegations which the guardians made against the master related to the stores and provisions, which it was asserted had been wasted, and the ratepayers' interests not properly looked after, because the master had delegated his duties to others, and had taken frequent and prolonged absences from the workhouse. It was also stated that the orders of the medical officers were neglected, the master having in some cases used his own discretion in not conforming to the dietary provided by the Board. The inquiry was concluded on August 10th, and the decision of the Local Government Board reached the Board of Guardians last week, so that the charge which we have frequently made of official delay cannot in this instance be repeated, but the decisions themselves deserve thoughtful consideration. With regard to the first charge, "the delegation to inmates of the workhouse of work in connection with the stores," the Board consider that "the master has not properly supervised the work devolving on his assistants, and that he has not devoted sufficient personal attention to the issue and receipt of workhouse stores;" or, in other words, they assert that the accusation made is a true one. The second complaint made against the master "that he was frequently and for prolonged periods absent from the workhouse," the Board consider to have been established, the master, in their opinion, having been absent in the evenings far too frequently and for too long periods. In reference to the third charge, "that the master made an entry in his books that forty-seven tons of stone had been used in the repair of the yard, while it was acknowledged that no such quantity had been used for the purpose," the Board consider that Mr. Thompson acted "most improperly in making an entry in his books not in accordance with facts, although they are satisfied it was not made with any fraudulent intent." In every particular it will be noticed, excepting that which concerns the medical officer, the Local Government Board have found the master to be in fault, and that the accusations made by the guardians have been abundantly substantiated, and yet they conclude their report with this remarkable sentence: "The Board consider that the master's conduct in the matters referred to as being very reprehensible and deserving of severe censure; but looking at his long period of service and to all the other circumstances, they have decided not to adopt the extreme course of requiring his resignation." As a result of this decision, we learn that the suspension imposed on Mr. Thompson was removed, and he was directed to resume his duties forthwith.

We can conceive few actions more disastrous to the right development of progressive philanthropy than this. It requires but even a cursory glance through our Commissioner's reports on workhouses and infirmaries to see that in too many instances the guardians are indifferent to the welfare of the poor whom they profess to guard, or else that they are dominated by their chief officials. But the St.

Saviour's guardians had fallen, so far as their workhouse is concerned, into neither of these errors, but with due regard to official procedure have sought the help of the supreme Board to move their delinquent official. Had they shown themselves wrong in their judgments the decision of the Local Government Board would have been comprehensible, but in every instance the result of the inquiry is to confirm their opinion, and yet they are submitted to the indignity of seeing the officer who has defied their authority reinstated in his position. Such a step is sure to result in a crop of insubordination. Who will obey the Board which has been publicly snubbed? And what will be the spirit among the officers and servants who are likely to serve under a master who having proved himself untrustworthy with regard to the stores, neglectful concerning the inmates, and capable of falsifying his books, is yet counted worthy to be again put at the head of a large institution? Such leniency is, we affirm, criminal, and all the more so because it has a deeper root than mere kindness to the accused official or the desire to curb what may be considered to be a too progressive Board. We have not space to enlarge, but in a sentence we affirm that the system by which the Local Government Board inspector becomes the judge in such inquiries is the cause of these lax judgments. The Local Government Board dare not declare that the master is unworthy to hold his position, because, if it did, it would be equivalent to affirming that the inspector had disgracefully neglected his inspector's duty in allowing him to retain it.

THE DRUG, CHEMICAL, AND ALLIED TRADES EXHIBITION.

THE Agricultural Hall last week was occupied by a trades exhibition at which the leading chemists and druggists showed their various specialities.

The Chemists' Aged and Mineral Water Association, Limited, exhibited many examples of table waters, both of the ordinary and of the medicinal strength. They also had siphons containing piperazin. Mineral waters were also exhibited by the Catley Abbey Natural Seltzer Water Company.

J. Defries and Sons showed the now well-known Pasteur filters in various forms with tests illustrating their proved efficiency. They also had on their stand cultures from the water which had passed through various other forms of domestic filters proving how inoperative these had been in preventing the transit of micro-organisms and disease germs.

There was a very good exhibit by Robinson and Sons, Chesterfield, of all kinds of antiseptic and other dressings, and at the same stall were also shown the bandage and pill-box shoots devised by Messrs. Reynolds and Branson, of Leeds, together with their new "Non-run-away" bandages, all practical and useful inventions.

Leslies, Limited, also had a very good display of dressings and bandages with tape and other plasters in every variety.

A very interesting stall was that in which Messrs. Cresswell Brothers and Schmitz, sponge importers, exhibited all sorts of sponges in various conditions, among which were some very fine examples of the flat Turkey sponges now so commonly used in abdominal section.

The stand of Messrs. Burroughs, Wellcome, and Co., was well stocked with the various preparations for which they are so well known. Kepler extract of malt with cod liver oil and without, "tabloids" of every kind, including the various animal substances now used in medicine, such as thyroid, thymus, suprarenal capsule, etc.; ophthalmic "tabloids," tea "tabloids," anti-diphtheritic serum, all sorts of inhalers, and samples of many of the newest drugs were to be found at this stall.

Messrs. Parke, Davis, and Co., also were not behindhand, having an extensive collection of drugs and medicinal specialities with many excellent novelties.

Messrs. Oppenheimer, Son, and Co., showed to what an extent the system of administering drugs in the form of "palatinoids" or "bi-palatinoids" may be developed. Among others were the different forms of animal substances used in medicine. A bi-palatinoid containing the ingredients for making Fehling's test seems likely to be of much service in bedside urine testing.

Among the exhibits shown by B. Kühn were various digestive preparations of papain, together with specimens of the fruit and seed of the carica papaya.

Messrs. Hockin, Wilson, and Co., showed many druggists' sundries.

Tidman and Sons, besides their well known sea salt, had specimens of the various soaps which they manufacture.

H. Silverlock exhibited every sort of label, and in fact almost every requisite made of paper, from account books even to fly papers.

The Sanitas Company exhibited sanitas in all its forms, as well as sulphur fumigating candles and other disinfectants.

Jeyes' Sanitary Compound Company showed their "fluid" and also specimens of "creolin" and "lano-creolin."

ASSOCIATION INTELLIGENCE.

NOTICE OF LAST QUARTERLY MEETING FOR 1895.

ELECTION OF MEMBERS.

A MEETING of the Council will be held on October 23rd, 1895. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before the meeting—namely, October 2nd, 1895.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, General Secretary.

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

MEMBERS are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

EAST ANGLIAN BRANCH.—The autumn meeting will be held at Thetford on Thursday, September 26th, under the presidency of Mr. G. E. Jeaffreson. Programme of proceedings:—12 noon. Meeting of Council at Town Hall. 12.30 P.M. General meeting at Town Hall. Dr. Pembroke Minns and Dr. Harris will welcome the members on behalf of the medical men of Thetford. Dr. Pembroke Minns will read a few Antiquarian Notes on Thetford. Report of Committee on Midwives Registration Bill. 1.30 P.M. Luncheon at Town Hall. Tickets 3s. 2.30 P.M. Resumed general meeting. Papers:—Dr. W. S. A. Griffith (London): The Early Diagnosis of Cancer of the Uterus and the Cases suitable for Operative Treatment. Dr. Mary Scharlieb (London): Our Duty towards Women who suffer from Abnormal Discharges or Pains, especially about the time of the Menopause. The following lady and gentlemen have promised to take part in a discussion on the above papers: Dr. Garrett Anderson, Sir F. Bateman, Mr. Cadge, Mr. W. Crowfoot, Mr. Morse, Mr. Mayo, Mr. Burton, Mr. Walker, Mr. R. H. Lucas, and Dr. Beverley. Clinical demonstrations will be given and specimens shown by Dr. Barton, Dr. Burton Fanning, Mr. Morse, and Mr. D. D. Day. 4.30 to 5.30 P.M. Reception by the medical men of Thetford in the grounds of St. Mary's House, kindly lent by Mr. Charles Burrol, J.P. Members wishing to visit some of the chief places of interest in Thetford are requested to communicate with Mr. Allan Smith, either before or at the meeting.—EDGAR G. HARRIS (Hyes), MICHAEL BEVERLEY (Norwich), THOMAS CAGE (Braintree), Honorary Secretaries.

NORTH WALES BRANCH.—The autumnal intermediate meeting will be held at the Castle Hotel, Ruthin, on Tuesday, September 24th, at 1 P.M. After the general Branch business the following papers will be read:—Dr. H. Drinkwater (Wrexham): A case of Trephining for Jacksonian Epilepsy. Dr. Judson S. Bury (Manchester): Some Points in the Investigation of Diseases of the Nervous System. Mr. J. Lloyd Roberts (Denbigh): Cases of Hernia. Mr. Thomas H. Hickerton (Liverpool): Mules' Evisceration of the Eye. Mr. W. Thelwall Thomas (Liverpool): Recent cases of Bone Surgery. Dr. Hugh R. Jones (Liverpool): The Bacteriological Diagnosis of Diphtheria. Mr. Hugh E. Jones (Liverpool): Case of Complicated Ear Disease in a Baby. Mr. Frank Edwards (Liverpool): The Treatment of Localised Eczema. Mr. Lawson Tait will call attention to several motions passed at the last annual meeting and move a resolution thereon.—W. JONES-MORRIS, Honorary Secretary, Portmadoc.

SOUTH MIDLAND BRANCH.—The autumnal meeting of this Branch will be held at Quex on Thursday, October 3rd. The following papers have been prepared:—Mr. R. A. Mithras: Two cases of Intestinal Obstruction successfully treated by Abdominal Section. Mr. George H. Percival: Some cases of Ovariotomy. Mr. W. H. Hall will bring forward a proposal: "That a provincial medical association be formed, in conjunction with the South Midland Branch, to combat the growing evil of commercial 'medical and societies' in the South Midland Counties."—**CHARLES JEWELL EVANS**, Honorary Secretary, Northampton.

WEST SOMERSET BRANCH.—The autumnal meeting of this Branch will be held at the Railway Hotel, Taunton, on Friday, October 21st, at 8 P.M. Dinner at 6.30. The subject as settled by the Council for discussion after dinner will be Club Practice, and the discussion will be opened by Mr. Abbott. Short papers or cases may be taken before dinner, and others afterwards. The Honorary Secretary will be glad to receive notice of any case or paper to be communicated to the meeting in the course of the next three or four weeks.—**W. M. KELLY, M.D.**, Honorary Secretary, Taunton.

NORTH OF ENGLAND BRANCH.—The autumnal meeting will be held at the Hydropathic Establishment, Hexham, on Thursday, October 3rd, at 4 P.M. The Honorary Secretary will be glad to receive notice of communications. The dinner after the meeting will be at the same place, at 4.45 P.M.; 6s. 6d. each, wine extra.—**G. E. WILLIAMSON, F.R.C.S.**, 8, Eldon Square, Newcastle-on-Tyne, Honorary Secretary.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.—The next meeting will be held on October 20th, at 4.15 P.M., at the Crown Hotel, East Grinstead. Members are requested to send notice of papers, etc., to J. W. BATTENHAM, Bank House, Grand Parade, St. Leonards, Honorary District Secretary.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.—The next meeting will be held at the White Hart Hotel, Reigate, on Thursday, October 10th, at 8.45 P.M., Mr. F. B. Hallows, of Redhill, in the chair. Dinner at 6 P.M.; charge, 12s. exclusive of wine. Agenda: Minutes of Croydon meeting. To decide when and where the next meeting shall be held, and to nominate a member of the Branch to take the chair thereat. Discussion on Diphtheria.—Introduced by Dr. Sidney Martin. Speaker: Mr. H. G. Pittman, who will show some cultures and slides. Medical: Dr. Washburn. Speakers: Dr. Holman, Dr. Gaiton, Dr. Adeney, Dr. J. G. Ogle. Surgical: Mr. C. J. Symonds. Speakers: Dr. Walters, Dr. Hodges, of the South-Eastern Fever Hospital. In its Relation to Public Health: Dr. R. D. R. Sweeting, Local Government Board. Speakers: Dr. Philpot, M.O.H. Croydon; Dr. Jacobs, M.O.H. Reigate. All members of the South-Eastern Branch are entitled to attend and to introduce professional friends.—**HENRY J. PRANGLY, Honorary Secretary.**

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.—The next meeting of this District will take place at St. Bartholomew's Hospital, Rochester, on Friday, October 18th, Mr. J. Holroyde, of Hamond Hill, Chatham, in the chair. Gentlemen desiring to read papers or exhibit specimens are requested to communicate with the Honorary Secretary, E. GROUND, 21 B., 1, Ashford Road, Maidstone, as early as possible.

SOUTH WALES AND MONMOUTHSHIRE BRANCH. A MEETING was held at the Swansea Hospital on Thursday, September 12th, at 4 o'clock. In the unavoidable absence of the President (Mr. Lock of Tenby), the chair was occupied by Mr. EVAN JONES, of Aberdare.

Confirmation of Minutes.—The minutes of the previous meeting were read and confirmed.

New Members.—Dr. W. Williams (County Offices, Cardiff). W. G. Thomas (Bridgend), W. L. Jones, M.B., C.M. (Treherria), Edgar G. Evans (Pontypridd), and S. Wallace (Cardiff) were elected members.

Papers, Cases, and Specimens.—Dr. LATIMER (Swansea): 1. On Apomorphine as an Emetic, with a Personal Experience; 2. Case of Sporadic Oretinism two years old, Treatment by Thyroid Extract followed by marked improvement.—Dr. HARRIS (Cardiff) showed for Mr. COLLINS, of Cardiff, a specimen of Enlarged Wandering Spleen simulating Ovarian Tumours, and read the notes.—Dr. LANCASTER (Swansea) read notes of a case of Varix of the Stomach, Death from Haemorrhage; specimen.—Mr. C. HERBERT HOPKINS (Swansea): 1. Photographs of case of Lipoma Nasi before and after operation, and explained that the masses had been dissected off. 2. Patient on whom he had performed Double Amputation below the knee joint; patient can walk without any support, and ride a bicycle with artificial limbs. 3. Patient in whom he had trephined in occipito-parietal region for Epilepsy, following an injury to that part of the skull three years ago; fits had occurred every eight or nine days before operation; since operation six weeks ago he had had one fit (the day after the operation). 4. Notes of a case of Ovarian Tumour with Twisted Pedicle; operation, recovery. Mr. Hopkins also showed the following specimens: 1. Uterus removed by Vaginal Hysterectomy for Malignant Disease; patient

recovered. 2. Uterine Appendages and two large Sub-peritoneal Fibroids removed from one patient; recovered. 3. Huge Ovarian Cyst; patient did well.—Mr. BROOK (Swansea): 1. A case of Double Harelip, in which to overcome flattening of the nose, the result of bringing the intermaxillary bone into position, the columella had been lengthened by a V-shaped incision and the septum by division. 2. A successful case of Laminectomy for Paraplegia caused by pressure by an abscess involving the theca, and situated at the apex of an old angular curvature. 3. A case after complete Erasion of the Ankle-joint by a modification of Arbuthnot Lane's method; the external malleolus being divided instead of the external lateral ligament. 4. A case of Excision of the Shoulder-joint for Osteoarthritis. Mr. Brook also showed the following specimens: 1. Imperforate Rectum and Congenital Stricture of Sigmoid Flexure. 2. Multilocular Ovarian Cyst and Cystic Ovary.

BORDER COUNTIES BRANCH.

THE twenty-eighth annual meeting was held at the County Buildings, Dumfries, on August 30th. The chair was taken by Dr. CONNELL, of Peebles, and there were about thirty members and visitors present. A vote of condolence was passed upon the death of Mr. Hall, of Carlisle, an original member and past President of the Branch.

Report.—The report of the Council was read and adopted. It was decided to hold a meeting at Kendal in the autumn, at Carlisle in the winter, and at Galashiels in the spring.

Election of Officers.—The following gentlemen were elected to fill the various offices:—**President:** Dr. Smith, Dumfries. **President-Elect:** Dr. Altham, Penrith. **Representative on the Council of the Association and Parliamentary Bills Committee:** Dr. Somerville, Galashiels. **Councillors:** Dr. Parker, Kendal; Dr. Lockie, Carlisle; Dr. MacLaren, Carlisle; Dr. Macdonald, Carlisle; Dr. Ross, Dumfries; Dr. Kerr, Dumfries; Dr. Huskie, Moffat; Dr. Menzies, Galashiels; Dr. Hamilton, Hawick. **Honorary Secretary and Treasurer:** Dr. Helm, Carlisle.

Benevolent Grants.—A sum of 10 guineas was voted to the Royal Medical Benevolent College at Epsom, and a similar amount to the Medical Benevolent Fund, from the accumulated funds of the Branch.

Vote of Thanks.—Dr. SMITH then took the chair, and, on the motion of Dr. SOMERVILLE, seconded by Dr. BARNES, a hearty vote of thanks was accorded to the retiring President (Dr. Connell), and he was elected a Vice-President.

President's Address.—Dr. SMITH then delivered his Presidential address, for which a vote of thanks was accorded by acclamation.

Dinner.—The dinner was afterwards held at the restaurant.

SPECIAL CORRESPONDENCE.

PARIS.

Dangers of Electrical Lighting.—General News.

THE numerous deaths among the staffs employed in the electrical lighting works has attracted the attention of the Minister of Public Works, who has asked the Paris Medical Academy to draw up directions concerning the treatment of those injured by contact with the wires, and also concerning the technical precautions to be taken. The medical treatment formulated by the Academy is the same for injury from electrical shock, no matter what is the nature of the current inflicting the injury. But the technical precautions differ according to the nature of the current. If the person injured remains in contact with the electrical conductors, the assistant who extricates the injured must be careful before commencing operations to have dry hands and wear a pair of thick flannel or stuff gloves, and not to take hold of the injured person by a region in perspiration. In non-interrupted currents the electrical conducting wires must not be cut. When the wire is cut it must be cut in two places. The medical treatment consists of placing the injured person where there is plenty of air, loosening the clothes, rhythmic traction of the tongue, rubbing the body, etc. M. Dupuy Dutemps has forwarded these directions to

the Prefects, urging them to make them known especially among engineers and staff of the Ponts et Chaussées entrusted with the electrical lighting of streets, to the directors of electrical stations, municipal authorities, medical men, and dispensing chemists. The instructions corresponding to the respective currents will be pasted on the wooden structures to which the poles are fixed.

An inquiry is being carried on at Sainte Mondane, a village in the Canton of Carleix, concerning a series of cases of poisoning, resulting from eating unhealthy meat. One death has occurred, and several people are ill.

Dr. Berlioz, Chef of the Grenoble Sanitary Service, states that the epidemic among the soldiers garrisoned in that city is not typhoid fever, but influenza of the gastro-intestinal form.

The substitution of Seine water in the Paris supply for spring water did not last long. Spring water was supplied on September 17th to those districts deprived of it on September 11th. On September 14th the third and fourth districts were supplied with spring water.

CORRESPONDENCE.

THE PROPOSED REORGANISATION OF THE INDIAN MEDICAL SERVICE.

SIR,—The suggestions of Mr. Ernest Hart for reconstruction and reform of the Indian Medical Service are founded, not only on his personal experience while in India, but receive the support of almost every administrative medical officer serving in India. Nor should this important fact be lost sight of, that the present system of promotions in the Indian Medical Service has given rise to feelings of discontentment and injustice on the part of several medical officers of that very service, in witness of which the *Civil and Military Gazette*, published at Lahore, wrote so long ago as December 10th, 1894. The absurdity was then pointed out, and has since been repeated elsewhere, of a "purely military medical service employed on civil work," and civil institutions officered by military surgeons, as also of the anomalies in promotion. Correspondence in the *Pioneer* during August, 1894, after the celebrated occasion of the speech at Simla of Principal Medical Officer of the Indian Medical Service showed that the military branch of the Indian Medical Service was rapidly going from bad to worse, and had no reason to congratulate itself on the future outlook. In short, Mr. Hart's suggested reform would set at rest jealousy, dispel friction, and allay discord, all of which exist at present, proved by the expression of public opinion before quoted. The *BRITISH MEDICAL JOURNAL* has adverted to these matters in past issues, and the military press at home has commented in adverse terms on existing arrangements.

It is generally believed that it is only in the civil branch of the Indian Medical Service that Mr. Hart's remarks have stirred up anger, for it sees in the necessary reform and reconstruction the destruction of a monopoly and the end of advancement to administrative military billets after years and years of purely civil experience, and acquisition of a competence in the latter practice.—I am, etc.,

BRIGADE SURGEON-LIEUTENANT-COLONEL I.M.S.

A QUESTION OF CONSCIENCE.

SIR—You are properly of opinion that if views such as those of the above letter be in the air, it is better to publish them: thus whatever is sound in them may survive, and the unsound be winnowed away. You are good enough to ask for my opinion on Miss Kenealy's letter, and to ask me to publish it; although I do not pretend to choose the good and avoid the evil better than my neighbours, yet, after some hesitation, I will express my fallible judgment on the matter.

One great difficulty meets me at the outset—namely, that Miss Kenealy, of set purpose, writes in a figurative and rhetorical style, which is out of my habit and far beyond my powers. It is natural to one who has so little of the poet in him as myself to try to drag down other people to his own level. At any rate, it must be forgiven to me, especially by the accomplished authoress, that I can only plod after her in

a humdrum fashion, and with my narrow vision attempt to define her position and my own.

After reading the letter many times I have endeavoured to reduce it to my own understanding. It seems to mean something as follows:

A physician is called in to a pregnant woman in whom abortion threatens. The disturbance is found to be due to syphilis. The physician retires to another room—the description of which seems to me to be unimportant—to write a prescription. There she sees a child of the same woman which she finds to be diseased. The diagnosis, so far as it is given to us, is very hazy, which is to be regretted, as the point is of some importance. One would, moreover, be glad to know why the mother was a "wreck." The loneliness of the child and its yearning for sympathy from a stranger seem irrelevant, unless we are to suppose that maternal instincts are atrophied in the face of inherited syphilis. However, the physician, finding the child an uncomfortable object, deprives the mother of the antidote prepared for her in order that the foetus *in utero* may abort. Uninspired as I am by higher motives, this seems to me a strong proceeding. Miss Kenealy will no doubt admit that it is constructively the same thing as to procure abortion.

Lacking the aid of my "conscience" and the moral support of "Nature" in these difficult places, I should have felt it my duty to seek a consultation if I thought that abortion were the thing to bring about. A consultation was, perhaps, less necessary in Miss Kenealy's case as she has communion with an intelligent agent whom she calls "Nature." Nature had gone for abortion, and was officiously attempting the deed without waiting for Miss Kenealy. "Nature" is a being visible only to the poet, and I am therefore deprived of her services. In my blind way I can only see a series of phenomena of which these syphilitic events form as much a part as more convenient events. I remember some other poet speaks of "Nature," and says that there is no mean in Nature but Nature makes that mean. However poets, like doctors, differ.

Miss Kenealy goes on, with some inconsequence and looseness of statement, to throw doubt upon antidotes as a class—perhaps mercury after all is not an antidote! Can it be that she was beginning to feel a little uncomfortable, and wanted to reassure herself?

Here, however, Miss Kenealy does enter the walks of science, had but one time to follow her. I presume that to call the poor child a Mongolian is also scientific? The small range of my own studies does not enable me to discuss this point. We are all such specialists nowadays. Sir H. Howorth will, I trust, throw some light on the dark saying.

A point more within my own knowledge is that so far from syphilitic children "tainting the human stream in an ever-widening output," these children for the most part, like rickety children, grow up strong enough; and so far from intensifying the pest, probably convey some degrees of immunity to their descendants. One of the most syphilitic children I ever saw is now a cultivated and distinguished man, one whom his devoted parents, his friends and his country could ill spare. Personally I congratulate myself, and a large circle of society, that Miss Kenealy was not at hand in the "handsome library" when his mother bore him.

Nature is no beneficent godmother; she is cruel and wasteful enough, and our progress consists in a steady defiance of her. The physician is called in to minister, in his blind way but to the best of his powers, to the relief of suffering; and to preserve the flame of life, which he is bound to regard as sacred, even in its tiniest sparks. We are the Vestals of this fire. What are we to think of a physician who, called in to fulfil his office, destroys hope of offspring and extinguishes the child-life within the mother's womb? And this, so far as it appears, in secret: the mother is not told of the plot, nor does the physician consult even the bishop of the disease. Miss Kenealy may say that the whole story is a parable, and that she has not the smallest desire to explain her views of Nature's wishes under cross-examination in a court of law. Even the Solicitor-General might demur to the artificial abortion of a potential thief.

May I, in conclusion, advise Miss Kenealy to tread the humble path of the mediciner apart from speculative philan-

throphy and from casuistical ethics which belong to priests and philosophers. I would not for a moment appear to turn a hard face to moral sympathy or moral indignation. Miss Kenealy appears in her letter in an amiable light, however startling her rush into the most difficult and ancient of ethical problems. But it is a truth older than Hume that a "moral sentiment" contains a feeling and an opinion; moreover, that the feeling may well be right but the opinion may well be wrong. To have humane feelings is good, and happily to many persons easy; but the sense of satisfaction they give to the possessor is no measure of the fitness of their application, which depends upon an intellectual process. It is in this analysis that I think Miss Kenealy's attitude is defective. —I am, etc.,

September 16th.

T.C.A.

THE DISCUSSION ON DIPHTHERIA IN THE SECTION OF MEDICINE.

SIR,—I have read in the BRITISH MEDICAL JOURNAL of September 14th Dr. Sidney Martin's reply to my letter of August 31st. It is with considerable pleasure that I find that on the majority of points we are in complete agreement, the main issue between us being whether the fatal accumulation of the diphtheria poisons is prevented by merely local treatment or is not. It is true that the local application of germicides have not, for the most part, met with such good results as we should have desired, but of their ultimate success I am most sanguine. Only in 1884 was the bacillus diphtherie revealed by Loeffler; therefore there is only a period of eleven years since a sure foundation was laid on which we could securely commence to work. Prior to this, although germicides were successful sometimes and were failures at others, we knew not why they succeeded or why they failed. That is not the case now, and I have no hesitation in saying that the failure must be attributed to our want of an early accurate diagnosis and not to any inefficiency on the part of some at least of the germicides.

What we, the practitioners, under whose care the majority of cases of diphtheria come *ab initio*, must clamour for is the establishment of centres, under a staff of able bacteriologists, to which we may be entitled to send specimens gratis, so that, at the earliest possible moment, we may know whether we have diphtheria to deal with or not when cases of septic and membranous sore throats present themselves before us. Then shall we be in a position to test the capabilities of germicides, and to prove their efficacy in diphtheria, and I, at least, am convinced that the result will not be unfavourable to them, or, at any rate, some of them.—I am, etc.,

Shaftesbury Road, W., Sept. 16th.

BROWNLOW R. MARTIN.

THE SERUM TREATMENT OF TUBERCULOSIS.

SIR,—While not professing conviction that Professor Magagnoli's serum treatment of tuberculosis will not share the fate of Koch's tuberculin, and yet commending the enthusiastic manner in which he has published his paper abroad I should like to say a few words in reply to Mr. William Catto, and to mention a few salient points which he seems to overlook.

It has been shown, to the satisfaction of the bulk of the medical world, by Hankin, Kitasato, Behring, and many others, that a normal animal organism can produce within itself when occasion requires a garrison of defensive proteids with which to repel the attacks of bacterial toxins. That we have not in every case yet been able to isolate these defensive proteids, or whatever else it may please us to call them, by no means disproves their existence.

We all know that some animals have natural immunity from the toxins of the anthrax bacillus. To what is this immunity due if not to a defensive proteid? And does it not seem within the bounds of feasibility that this substance might be isolated and used to confer immunity on other animals?

Mr. Catto says: "Are not all animals that are suffering from the actual disease continually subjected to the extract of living bacilli? Do they become immunised? They never do." Arguing from that premise is, in my opinion, where he admits a fallacy into his reasoning. Let me put it in this way. Why do these animals have tuberculosis at all? They

are not born with it. No, in most, if not all, cases it is acquired. That is to say they are born with or may have acquired the predisposition to this particular disease, or, in other words, when attacked by the tubercle bacillus their tissues do not have the power of producing this peculiar defensive proteid which would enable them to resist the dread disease. May not that also be the reason they do not, as he states, become immunised?

It may be asked—Do we know of any analogous case in which, on account of some deficiency in the organism the therapeutics of Nature cannot be brought into play? We do, in the case of the well known hæmorrhagic diathesis, where from some as yet unknown cause Nature fails to arrest hæmorrhage owing to the absence of all the essentials to coagulation of the blood.

It seems probable that when a normal healthy animal is inoculated with a specific bacillus producing a specific toxin its tissues at once set about producing antitoxin to antagonise this toxin. The healthier the animal and the greater the number of inoculations the more antitoxin would be produced.

More wonderful things have been achieved by human science. Why should we not try to isolate this antitoxin and administer it to animals not having the power of producing it for themselves?

No need to let us go blindly with eyes bandaged with one fact or theory, but let us at least follow up our theories until they are upset by some stronger reasoning than that of the writer of the letter referred to.—I am, etc.,

Bradford, Sept. 16th.

WILLIAM MITCHELL.

PROFESSIONAL ADVERTISING.

SIR,—The BRITISH MEDICAL JOURNAL of September 14th is rather uncomfortable reading for some of us. But surely the profession is becoming too tender as to publicity for its members. We are now told that lantern lectures, ambulance lectures, and the writing of popular scientific books for the use of the unlearned, are means of committing this sin of "professional advertising." I suppose that these things will one day come under the ban of the all-powerful General Medical Council as being "infamous conduct in a professional respect."

But who so fit as a medical man to give the public scientific instruction, supposing that he possesses literary taste or the power of using language well for lecturing? And why are doctors to be the only men who may take no part in the general advance in popular science as a recreation which is going on round us to-day? It is rather hard upon the men who have such gifts, and who enjoy using them, and I maintain that every man so situated is bound to make use of his talents for the public good, just as much as a member of any other profession.

As to popular lecturing being effective as an advertisement, I can speak from some exceptional experience. For many years I have delivered lectures to working men's clubs in connection with Oxford House and other institutions, and I have as frequently given lectures to more favoured audiences in the way of wealth and social position; but I can distinctly say that my doing so has rather detracted from my success as a practitioner. I should have done better to employ my leisure hours in those social tricks and koo-toos amongst the well-to-do, which the profession strangely allow to pass as perfectly free from suspicion of "professional advertising."

If we treat the public as beneath our notice, and avoid taking them into our confidence in matters scientific; and if we refrain from publicity upon grounds of ethical sensitiveness, the public will only put us down as a set of pompous beings who hide their want of knowledge under an appearance of mystery akin to that used by the medicine men of savage tribes, and to the methods of the old-time quacks.

Perhaps the high priests of medical ethics will allow us to take part in public scientific work if each man wears a disguise of some sort, and uses an assumed name? In what way can a lantern lecture—say, upon the microscope or some other popular scientific subject—be classed as a professional advertisement? Or who is to give ambulance lectures if for a doctor to do so is "professional advertising"? Who is to write popular books upon hygiene, physical education, and

similar topics, if medical men are forbidden? The whole thing is an absurdity.—I am, etc.,

September 14th.

HERBERT.

SIR,—I read with great interest in the JOURNAL of September 14th, the report of the proceedings in the Section of Ethics at the late annual meeting, and more especially the paper read by Dr. Potter on Professional Advertising. Every medical practitioner must cordially endorse the greater portion of what was so well advanced by Dr. Potter, and also the opinion so generally expressed by members taking part in the discussion, that instruction in medical ethics should form part of a medical student's education. This system of instruction is without a doubt the proper course to pursue, but how can it be carried out when the extramural teachers, who are supposed to be our present and future leaders, are such sinners in their methods of advertising? What value can their teaching by precept possess, when they set such a bad example?

Is it not the case that the neighbourhood of all our large teaching hospitals is placarded over by bills, some printed in red, others in black, intimating that Dr. ——— is to open a class here, and Mr. ——— there, all with the very innocent purpose of being intended for, and read by medical students alone?

Is this the sole object of these advertisers? If so, why do they distribute their bills broadcast to be pasted on boards provided by all the instrument makers, and exhibited in all the druggists' windows throughout the city?

If their objects were so innocent, would it not be enough to put up their bills at the beginning of a session in those places where medical students congregate or pass, that is, within the hospital gates, and within the vestibules of the various class rooms, and where they could not be read by the general public?

I am afraid, however, that looking at the question fairly, most people would be inclined to attribute a different motive to their action. I would, therefore, heartily support the opinion expressed by several members at the meeting, that we should begin with the heads of the profession in putting down this unfair and iniquitous advertising habit, and not be constantly striking at the poor "strugglers for existence," who are practically only doing in their own way what the so-called leaders are doing in theirs, twice every year.

Until the teachers show a better example by confining their advertisements to places easily accessible to students, but shut off from the general public, it is hardly possible to expect the fringes of the profession to walk in the straight path.—I am, etc.,

Edinburgh, Sept. 16th.

MICHAEL DEWAR, M.D.

THE MIDWIVES' BILL.

SIR,—I will thank you for space for some remarks on the above. If midwives are allowed to take charge of cases whether natural or not independent of doctors, their usual modesty may be relied on to make short work of the claims and the interests of the faculty. Dr. Smyly is hardly acquainted with the state of things existing in the country, when he states that there is little or no friction in Ireland between doctors and midwives. I am sorry to be obliged to state that this is not the fact, and the Rotunda and Coombe Hospitals are responsible for this, as they never exercise any control over them once they are qualified. In order that they should be able to do this they should give conditional qualifications, and publicly withdraw them where the midwife would undertake duties beyond her sphere. I am personally aware of loss of life by their presumption. The proposal to make them subordinate to, and in the leading strings of the district health officer would be an excellent proposal, if the latter were not allowed to practise.

To sum up, I would allow no midwife to attend to any case whatever without a doctor looking in, at all events; and, too, I would enforce this by the withdrawal of her certificate, or, as they are encouraged to call it, their diploma. It is not clear to me but that there ought to be an inquest in every case of death in childbirth, as well as in every case of still-born infants. A case occurred to my knowledge where the intestines were dragged out by a clumsy practitioner, and where the case was hushed up by the midwife; and another

case where a midwife allowed the patient to die from a piece of retained placenta, hemorrhage continuing off and on for three months after the birth.—I am, etc.,
Cashel, Sept. 16th.

THOMAS LAFFAN.

ANTI-STREPTOCOCCIC SERUM.

SIR,—I have read with interest the paper by Dr. Bokenham on anti-streptococcic serum. As Dr. Ruffer is for the present incapacitated from work and as Dr. Bokenham mentions that similar work has been carried out in Continental laboratories, may I point out that Dr. Ruffer and I, as early as the beginning of this year, immunised horses against both the diphtheria bacillus and the streptococcus pyogenes, and other horses against the streptococcus erysipelas, for the production of therapeutic serum.

In fact Dr. Ruffer was, I believe, the first to publish the method of immunising horses against the streptococcus, and an abstract of his lecture appeared in the BRITISH MEDICAL JOURNAL of August 3rd, page 306.

The horses were shown to the members of the British Medical Association who visited the Institute farm at the last meeting.—I am, etc.,

WILLIAM ROBERTSON, M.R.C.V.S.,

Assistant British Institute of
Preventive Medicine.

Sudbury, Sept. 17th.

MEDICAL AID FREE! WITH A POUND OF TEA!

SIR,—Some kind friend has afforded me the opportunity of disclaiming my connection with "Bryan Bros. Medical Aid Scheme," by sending me a cutting from the BRITISH MEDICAL JOURNAL of September 14th.

Unfortunately, being one of the medical men whose names appeared on the card such as you describe, I hasten to inform you how it was I became associated with the scheme. Some time about the end of last June, I was waited upon by an agent of Bryan Bros., who pointed out to me the great advantage such a scheme would be to the poor. I accordingly accepted the appointment, and a few days after went away on my holidays.

On my return the very great mistake which I had made was explained to me, and on July 24th I sent in my resignation, copy of which I now enclose. In a few days after, the agent called to see me, and we arranged that I should refund the money paid to me in advance, deducting whatever amount I was out of pocket, and thereby cancelling my agreement at once. I have much pleasure in likewise enclosing for your perusal the receipt given me for the money which I returned.

I hope, Sir, you and your readers will be satisfied with the above explanation, and believe that I am not—and have not been since the end of last July—in any way connected with Bryan Bros.' Medical Aid Scheme.—I am, etc.,

Liverpool, Sept. 17th.

A. PAUL SWANSON, L.R.C.S.I.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL STAFF EXCHANGE.

The charge for inserting notices respecting Exchanges in the Army Medical Department is 2s. 6d., which should be forwarded in stamps or post office order with the notice. The last post on Wednesday is the latest by which these announcements can be received.

A MEDICAL OFFICER of field rank, who expects to go to India in January, desires an exchange with an officer who will have about two years or longer to remain at home. Liberal terms. Reply, stating date of arrival home, to A. M. S., care of Messrs. Holt and Co., 17, Whitehall Place, London, S.W.

A SURGEON-MAJOR serving in Bengal wishes for an exchange which would give him about three years at home. Address, stating terms, to S. L. H., care of Messrs. Holt and Co., 17, Whitehall Place, London, S.W.

A SURGEON-MAJOR, with two years to complete Indian tour, is desirous to exchange home.—Address No. 456, BRITISH MEDICAL JOURNAL Office, Strand, London.

THE NAVY.

The following appointments have been made at the Admiralty: ALFRED E. WRIGHTMAN, Surgeon, to Haslar Hospital, September 18th; FREDERICK J. LILLY, Surgeon, to the Katoomba, September 18th; WILLIAM A. WHITEHEAD, Surgeon, to the Royal Marine Division, Portsmouth, September 23rd; RICHARD F. BATE, Surgeon, to the Briton, September 25th.

THE ARMY MEDICAL STAFF.

PRINCIPAL SURGEON-LEUTENANT COLONEL R. T. BROWN officiates as Principal Medical Officer, Rawul Pindies District, vice Brigade-Surgeon-
Lieutenant Colonel C. F. Follock.

INDIAN MEDICAL SERVICE.

The promotion of Surgeon-Lieutenant Colonel C. J. W. MEADOWS, Bengal Establishment, which has been already announced in the *Barisan Medical Journal*, has received the approval of the Queen.

Surgeon-Lieutenant Colonel J. A. LANGE, M.D., Madras Establishment, has retired from the service, September 24.

Brigade-Surgeon-Lieutenant Colonel A. H. SEAMAN, Bengal Establishment, operating as Principal Medical Officer, Peshawar District, vice Brigade-Surgeon-Lieutenant Colonel R. T. BROWN, Army Medical Staff.

Brigade-Surgeon-Lieutenant Colonel A. L. HACKETT, late Madras Establishment, has been granted the extra pension of £200 per annum due to the Madras Establishment.

THE YEOMANRY AND RIFLE VOLUNTEERS.

MR. OLIVER CALVERT MAURICE is appointed extra Surgeon-Lieutenant in the Royal Welsh Yeomanry (Prince of Wales's Own Royal Regiment), September 18th.

Surgeon-Lieutenant J. S. FORREST, 2nd Northumberland (Percy) Artillery, Western Division Royal Artillery, is promoted to be Surgeon-Captain, September 18th.

MR. JAMES BLACK MILNE, M.B., is appointed Surgeon-Lieutenant to the 4th West Riding of Yorkshire Artillery (Western Division Royal Artillery), September 18th.

Surgeon-Lieutenant J. ANDERSON, M.B., 8th Volunteer Battalion the Royal Scots (Lothian Regiment), is promoted to be Surgeon-Captain, September 18th.

BANGALORE WATER SUPPLY.

EPIDEMICS OF TYPHOID FEVER.

THE notoriety that Bangalore has acquired as a very hotbed of enteric fever owing to the bad water supply for the troops (which is provided from a tank supplied by an open channel passing through a native bazaar, while forming part of the wall of the supply channel), is the main source from the same area has received recent notice through a correspondent to the *Pioneer*. He writes under date August 11th, as follows: "That a water supply is a need of the first importance for this large civil and military station cannot be gainsaid, and the dwellers in the Cantonment feel all the more impatient that the matter shall be settled, inasmuch as the Mysore durbar is fast completing its own scheme for bringing water to the Petah and the humbler of its subjects. It is impossible also not to regard this death of a good water supply as being in part responsible for the terrible amount of sickness and mortality which has this year, and especially during the past month or so, carried off so many British officers from our midst. The tank from which the majority of our troops are supplied is a natural reservoir in which weeds, duck, fish, and, worst of all, sewer drainage and catchment effluents all play their part. It is nothing less than scandalous that the very rudiments of municipal hygiene should be neglected in this way, but so it is. We have had three or four deaths among British officers since I wrote last."

We have since been informed that somewhat tardily Mr. Ernest Hart's suggestion that all such epidemics should be promptly met by boiling the drinking water under supervision has been carried out, and with the happy result of putting an end to the epidemic. We see it stated that it is in contemplation to systematically employ the Pasteur filters as in the French military stations, and we may hope that the general application of this system in India, and pending the introduction of pure water supplies which may be costly and difficult, typhoid fever, which has for the last few years been increasing in the British army in India, may be completely stamped out.

THE SUBORDINATE MEDICAL DEPARTMENT, INDIA.

THE administration of the Military Assistant Surgeon and Military Hospital Assistant branches in the Subordinate Medical Service of Madras and Bombay has been transferred from Government Presidencies to the Surgeon-General with the Government of India, with effect from October 1st, 1895. The Surgeon-General will dispose of all questions concerning recruitment, pay, pension, promotions, and disposal for duty of medical subordinates with army or local Government. Efforts will be made to detach subordinates to territorial areas from which they are drawn, but in emergency they may be employed in any part of India. This arrangement has been approved by the Secretary of State in view of improving the mobility and general efficiency of this class of public servants.

I.M.S. UNIFICATION.

THE unification of the Indian Medical Services in the three Presidencies will shortly be carried into effect. It is part and parcel of the army reorganization scheme, says the *Pioneer*, and only awaits the formal sanction of the India Office. The three services will be amalgamated, and will be worked as at present through the Surgeon-General with the Government of India.

ALCOHOLIC INSANITATION.

ALCOHOLIC insanitiation having received frequent notice in our columns, and subsequent Parliamentary questioning, it is gratifying to find a technical paper, the *Builder*, of September 7th, defending its views as follows: "The recent questions in the House of Commons as to the sanitary condition of Aldershot have elicited very unsatisfactory information from the responsible officials. It is admitted that there have been a number of cases of diphtheria, and a very large number of sore throats and cases of diphtheria and 300 cases of sore throat, the latter most probably of septic origin. All that the officials can say as to these diseases is that it is thought they have arisen from the opening of old drains for the purpose of alterations

and improvements. It is obvious (says the *Builder*) that if the opening of old drains is the cause of these attacks, that the state of the drains is a disgrace to the nation. Edifices under Government control are in a worse sanitary condition than ordinary private buildings."

THE ARMY MEDICAL SERVICE.

A.M.S. writes: The fact that there were only ten candidates for fifteen vacancies at the last competitive examination of the Army Medical Service proves that the reputation of adverse and injudicious criticism exercises a most pernicious influence. In these days of competition in which the majority of medical men find a difficulty in earning a moderate income, far more a comfortable independence, you incur a great responsibility in lending the weight of your opinion and authority against service in the Army Medical Staff as a means of livelihood. There does not exist any better field for the average medical man as regards both pay and experience. I undertake to be able to show conclusively that service in the Army Medical Staff not only compares most favourably with any other opening in private medical life but that the advantages are unequalled. I venture to predict that when young medical men realise the true facts that there will be one assured and not ten candidates for every fifteen vacancies. I may add that with ordinary care and prudence a man can live comfortably on his pay, and that his pay in India, provided he does not wish to remit money to England, is practically more than the equivalent of his promised pay on appointment at home, by which I mean that he can enjoy more comfort and indulge in more pleasures in India on his rupees (which only suffer depreciation by the exchange) than he can in England on his pay. I will with pleasure give the fullest information to anyone who may desire it either privately or through your columns.

* We print this letter verbatim because it is altogether singular in the mass of communications on the same subject that reach us. We notice some inaccuracies. We understand there were upwards of twenty candidates for the thirteen or fifteen vacancies in the late competition, but only ten obtained sufficient qualifying marks, now 50 per cent. instead of 30 formerly.

Whether our criticism on the Army Medical Service have been "adverse and injudicious" we leave to the better judgment of our readers; they have, however, always been made with the sole object of elevating the status and advancing the best interests of the officers. We are glad to find even one of the latter content with his lot; but we would ask him to consider what that lot would have been without the disinterested advocacy of the *BRITISH MEDICAL JOURNAL* and the intervention of the Parliamentary Bills Committee of the British Medical Association. Our correspondent has promised to demonstrate the "unequalled advantages" of the Medical Staff, which hitherto have never been apparent either to us or our numerous correspondents. It is not fair to accuse us of spoiling the late competition. Very little has lately appeared in these pages on the Army Medical Service, and nothing surely to cause a sudden running dry in the supply of candidates.

But from what we can learn there are not a few "pernicious influences" at work in the schools which have brought about the result, and will soon tend to bring about another crisis in the department. Among the causes which prevent candidates coming forward are the continued denial of equal rank to medical officers compared with other army officers; the social boycotting and ostracism to which they are often subjected in garrison towns, and the disgraceful blackballing in certain military clubs; the hard conditions of foreign service, by which a maximum tour in the tropics is succeeded by a minimum at home; the present of their best years to the Indian Government on a minimum rate of depreciated rupees; the continual cutting off of administrative appointments, or the reduction in prospective prizes, etc. These are among the causes which bring about a dearth of candidates and prevent them coming forward in their "hundreds," and not the "adverse and injudicious criticisms" which our correspondent blames.

MEDICO-LEGAL AND MEDICO-ETHICAL.

MEDICAL LIBEL CASE.

THE rolling Under-Sheriff for Warwickshire, Mr. H. W. Bickleton, and a jury, held an inquiry on September 14th, to assess damages in the libel case of Dr. Henry Stone, of Walsall v. Dr. S. Johnson, photographer's artist, of the same place. Mr. Parfitt, who appeared for the plaintiff, according to the report in the *Warwickshire Gazette*, explained that the libel complained of in the hearing of which defendant had refused judgment to go by default—was one calling for substantial damages. Dr. Stone attended defendant's mother until her decease. Death was due to erysipelas, but plaintiff had reason to believe that there had been an abscess, and did not feel justified in giving a certificate without the facts having first gone before the coroner. An inquest was held, and the publicity seemed to have given defendant serious annoyance, so he wrote a letter to the *Warwick Observer*. This letter contained the libel complained of, and in respect of which damages were claimed. The charges contained were of a kind likely to do a professional man serious injury. A paragraph in the original draft letter, struck out by the editor of the paper, but still seen by him and the printers, was as follows: "The only conclusion I can come to is, firstly, that she was in a medical aid society, and I suppose the doctor was discredited with the amount they pay to him; and secondly, the inquest fee of £1 is proved too great a temptation for him when he thought there was the least

* *Full Parliamentary Report, Times, August 20th, 1895.*

possible chance to obtain an inquest." That paragraph was crossed through, and the following words substituted: "Such inquests are brought about for the sake of the inquest fees. The doctor, I believe, receives a guinea." The plaintiff then gave evidence, asserting that he told defendant that if he, Dr. Shore, gave a certificate, he would have to put down as the cause of death "erysipelas, caused by an accident," and that would be sufficient to refer the matter to the Coroner. There was no foundation for the suggestion that he wanted to bring about an inquest in order to get the guinea fee. It was the modern idea that where erysipelas prevailed there must have been abrasion beforehand.—Defendant expressed the desire to put in the depositions taken at the Coroner's inquest.—Mr. Parry: If Mr. Johnson would take my advice, he would try to prove that Dr. Shore has not suffered much damage.—In answer to defendant, plaintiff said his father paid him a weekly salary. This allowance had not been reduced or his practice stopped.—The Under-Sheriff said it was not necessary to prove any specific damage; it was sufficient to assume that a professional man must suffer damage from statements like those defendant had made of the plaintiff.—Defendant said that an apology had been offered, and that the statement concerning the guinea had not appeared in the paper. The statements there appearing were correct, and he was prepared to stand or fall by them.—The Under-Sheriff said that defendant, having chosen not to avail himself of his right to defend the action brought against him, must be taken to have admitted all the statements in the plaintiff's claim. The jury should give a sufficient sum to vindicate the plaintiff's character. He was bound to say that the defendant, by still persisting in the truth of this libel, had made matters considerably more serious.—The jury assessed the damages at £100.—The Under-Sheriff (to defendant): I think you are a very lucky man.

MEDICAL ETIQUETTE IN QUEENSLAND.

TOWNSVILLE, QUEENSLAND.—Assuming, as we do, that Dr. H. F.'s statements in relation to Mr. E. H. and Mrs. J. and N. convey a fairly just version of the respective facts, and that personally he has given no cause therefore, we would observe with reference to the alleged procedure of Mr. E. H. that, if it be as represented, such conduct was exceptionally unethical and indefensible; and the same condemnatory remark also applies more or less to the action of Dr. N. At the same time, we are of opinion that Dr. H. F. erred in not asserting his position and retaining the patients.

With regard to Dr. J., the case as related indicates a regrettable lack of professional courtesy, and of a due sense of his moral obligation to do unto others as he himself would wish to be done by, and leads us to infer that an extended knowledge and practice of the principles laid down in the *Code of Medical Ethics* are highly desirable in the locality in question.

We deem it well to add that willingly as we would otherwise give insertion to our Antipodean correspondent's communications, their undue length render it impracticable in view of the unavoidable limited space accorded to medico-ethical questions.

PROFESSIONAL ADVERTISING.

W. E. R. writes: I enclose herewith two cuttings from to-day's (September 15th) *Telegraph*. When Members of the College of Physicians are reduced to paying guineas for advertisements of this sort, we can scarcely be surprised at the cheap dispensary touts. Surely the College of Physicians ought to be able to control its members.

"Dr. Mortimer Granville, who has been paying some visits to Cornwall, has returned to 14, Manover Square."

"All Society and Fashionable Paragraphs inserted in *The Daily Telegraph*, except those relating to official incidents, will be charged at a minimum rate of one guinea for two lines, each succeeding line 10s. 6d. additional."

"* We have received a number of other letters by the same post calling attention to this advertisement, and denouncing it."

ANOTHER correspondent sends us the following extract from the *St. Pancras Gazette* of September 14th:

"Dr. Richard P. Long has returned to his residence, 69, Queen's Crescent, Haverstock Hill, N.W., after a five weeks' holiday in Switzerland. The many friends and patients of the popular and esteemed physician, who, by the way, is one of our most assiduous vestrymen, will learn with pleasure that he has derived great benefit from his well-earned rest in the charming region of Lausanne."

HOSPITAL APPOINTMENTS.

M.A. M.B.—Our correspondent's statement is not sufficiently exact to enable us to offer other than a contingent solution of the difficulty referred to. He has omitted to furnish us with two important factors in the case, namely, as to the rule which governs the appointment of honorary physicians to the local infirmary, and the respective degrees of A. and B. Assuming, however, that B. the senior surgeon to the out-patient department, is legally qualified to hold the appointment, we are distinctly of opinion that, *cedens paribus*, B.'s claim to the vacant office is superior to that of A., who has never in any way been associated with the institution.

OUTDOOR ASSISTANTS AND HOLIDAYS.

MAC.—A correspondent asks what length of holidays an assistant is entitled to without loss of salary. Strictly speaking, it could hardly be argued that he was entitled as of right to any, but most practitioners allow an assistant who has been with them a year or more a week or a fortnight, provided of course it is the intention of the latter to stay with his principal at least another year. No one would be expected to allow an assistant who was going to leave him in a few months a holiday however long he might have been with him.

PHYSICIAN AND SURGEON.

ZED.—In reply to a correspondent we would refer him to an editorial article on the subject which will appear shortly in the *BRITISH MEDICAL JOURNAL*.

UNQUALIFIED PRACTICE AND COVERING.

ASSERION.—The proper course for dealing with medical practitioners who cover unqualified men is to bring their conduct before the General Medical Council. To prove practice by unqualified men there should be evidence of visiting and prescribing, and not merely visiting and dispensing.

ASSISTANTS AND THE "COURTESY CALL."

B. A. G. will find in the *Ethical Code*, under the heading of Intraprofessional Etiquette, chap. iv, rule 2, the following appended note: "N.B.—It may be prudent to note, in passing, that practitioners in the position of 'assistants' are, as a rule, exempt from making or receiving the call, and in either case it should be omitted."

Z. Y. X.—We cannot answer the question without full copy of the agreement referred to being sent to us.

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF DURHAM.

FIRST EXAMINATION FOR THE DEGREE OF BACHELOR IN MEDICINE.—The following candidates have satisfied the Examiners:

Elementary Anatomy and Physiology, Chemistry with Chemical Physics, and Botany with Medical Botany.—A. A. Bolton, College of Medicine, Newcastle-upon-Tyne; J. W. H. Boyd, College of Medicine, Newcastle-upon-Tyne; J. Scott, Middlesex Hospital; R. F. Richardson, Westminster Hospital.

Chemistry with Chemical Physics.—E. G. E. Arnold, M.R.C.S., L.R.C.P., St. Thomas's Hospital; E. C. Bailey, King's College Hospital; T. Streetfield, M.R.C.S., L.R.C.P., University College Hospital, London.

Chemistry with Chemical Physics, and Botany with Medical Botany.—J. H. Martin, College of Medicine, Newcastle-upon-Tyne.

FIRST EXAMINATION FOR THE DEGREE OF BACHELOR IN MEDICINE (NEW REGULATIONS).—The following candidates have satisfied the Examiners.

Elementary Anatomy and Biology, Chemistry and Physics.—Honours, First Class: J. Milligan, College of Medicine, Newcastle-upon-Tyne. Honours, Second Class: E. Giffon, College of Medicine, Newcastle-upon-Tyne; J. Muirhead, College of Medicine, Newcastle-upon-Tyne; N. C. Bates, College of Medicine, Newcastle-upon-Tyne; N. Roberts, College of Medicine, Newcastle-upon-Tyne; H. B. Fawcett, College of Medicine, Newcastle-upon-Tyne; W. Siam, Mason College, Birmingham; J. T. Johnson, College of Medicine, Newcastle-upon-Tyne. Pass List: G. O. M. Dickenson, College of Medicine, Newcastle-upon-Tyne; R. H. Garbutt, College of Medicine, Newcastle-upon-Tyne; W. J. Harrison, College of Medicine, Newcastle-upon-Tyne; C. T. Holmes, College of Medicine, Newcastle-upon-Tyne; W. J. Symes, Sheffield School of Medicine.

Elementary Anatomy and Biology.—L. J. Blandford, College of Medicine, Newcastle-upon-Tyne; C. H. Brookes, College of Medicine, Newcastle-upon-Tyne; E. H. Cooke, St. Thomas's Hospital; J. J. French, College of Medicine, Newcastle-upon-Tyne; A. Hines, College of Medicine, Newcastle-upon-Tyne; E. Swainston, College of Medicine, Newcastle-upon-Tyne; T. B. Watson, College of Medicine, Newcastle-upon-Tyne.

Chemistry and Physics.—J. H. Halliday, London Hospital; E. Inman, College of Medicine, Newcastle-upon-Tyne; R. A. R. Lankester, University College, London; J. Macfadyen, College of Medicine, Newcastle-upon-Tyne; R. F. Moorhead, Bristol Medical School; A. C. Ney, College of Medicine, Newcastle-upon-Tyne; G. B. Pictou, College of Medicine, Newcastle-upon-Tyne; J. E. Sidgwick, College of Medicine, Newcastle-upon-Tyne; D. H. Weir, College of Medicine, Newcastle-upon-Tyne.

Physics.—A. M. G. Walker, College of Medicine, Newcastle-upon-Tyne. *Elementary Anatomy, Chemistry, and Physics*.—K. H. Vincent, St. Bartholomew's Hospital.

REGULATIONS OF THE UNIVERSITY OF BRUSSELS.

DR. WALTER REEVE (28, Victoria Street, Westminster) writes with regard to the regulations of the University of Brussels, that materia medica and pharmacology are now taken in the 1st Doctorate. These subjects were presumably before included under the head of General Therapeutics. He states, also, that ophthalmology has been removed from the 2nd and been placed in the 3rd Doctorate. Another alteration appears to be that rejected candidates must present themselves for re-examination within the academical year, or otherwise they will be required to pay the matriculation fee over again. Dr. Reeve will supply copies of the regulations and answer the inquiries of intending candidates in this country.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next examination for the certificate of competence in nursing and the attendance on the insane granted by this Association will be held on Monday, November 4th. Candidates can obtain from the Registrar, Dr. Spence, Burntwood Asylum, near Lichfield, a schedule, which must be filled up, signed, and returned to the Registrar not later than Monday, October 5th.

OBITUARY.

LOUIS RALSTON HUXTABLE, M.B., C.M. EDIN.

THE death is reported of Dr. L. Ralston Huxtable, of Sydney, New South Wales. The deceased, who took the degrees of M.B. and C.M. Edin. in 1881, was honorary physician to the Sydney Hospital, the Sick Children's Hospital, and the Walker Convalescent Hospital, and also held the appointment of Visitor of Asylums for the insane. He had been for the last three years Honorary Secretary to the New South Wales Branch of the British Medical Association. The death of Dr. Huxtable at the early age of 39 has caused wide regret throughout the profession and the extensive circle of his acquaintance. The cause of death was pneumonia consequent on diphtheria. The funeral was very largely attended by the members of the medical profession, the general public, and the personal friends of the deceased.

JOHN M. FOX, M.R.C.S. ENG.

THE death is reported of Mr. John M. Fox, of Lymm, at the age of 64. Mr. Fox, who obtained the diplomas of M.R.C.S. Eng. and L.S.A. in 1864, was Medical Officer of Health for the Mid-Cheshire Combined District. Prior to receiving this appointment he was Medical Officer of Health for the Cuckermouth Combined Sanitary District. Latterly the deceased had been in failing health and had been unable to attend to his professional duties. He seemed to derive but little benefit from a recent stay at the seaside, and, despite medical skill, he gradually grew weaker and died on September 12th, the cause of death being pneumonia.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 8,156 births and 3,917 deaths were registered during the week ending Saturday, September 14th. The annual rate of mortality in these towns, which had been 19.9 per 1,000 in each of the three preceding weeks, declined again to 19.3 last week. The rates in the several towns ranged from 11.7 in Plymouth, 13.1 in Norwich, and 13.6 in Croydon and in Nottingham to 32.7 in Blackburn, 33.5 in Burnley, and 37.5 in Sunderland. In the thirty-two provincial towns the mean death-rate was 22.0 per 1,000, and was 6.8 above the rate recorded in London, which was only 15.4 per 1,000. The zymotic death rate in the thirty-three towns averaged 4.9 per 1,000; in London the rate was equal to 2.6 per 1,000, while it averaged 6.3 in the thirty-two provincial towns, and was highest in Blackburn, Hull, and Sunderland. Measles caused a death rate of 2.0 in Blackburn; whooping-cough of 1.3 in Bradford and 1.8 in Bolton; "fever" of 4.1 in Sunderland; and diarrhoea of 7.0 in Bolton and in Manchester, 7.4 in Blackburn, 8.4 in Burnley, 11.4 in Sunderland, and 13.0 in Hull. The mortality from scarlet fever showed no marked excess in any of the large towns. The 75 deaths from diphtheria in the thirty-three towns included 35 in London, 5 in West Ham, 2 in Birmingham, and 2 in Burnley. Two fatal cases of small-pox were registered in London, and 1 in Manchester, but not one in any other of the thirty-three towns. There were 397 cases of small-pox under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital on Saturday, September 14th, against 342, 319, and 329 at the end of the three preceding weeks; 42 new cases were admitted during the week, against 65, 36, and 36 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 2,567, 2,567, and 2,600 at the end of the three preceding weeks, had further increased to 2,674 on Saturday last, the 14th inst.; 563 new cases were admitted during the week, against 386, 384, and 336 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

DURING the week ending Saturday, September 14th, 321 births and 450 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had increased from 18.2 to 19.1 per 1,000 in the three preceding weeks, declined to 18.8 last week, and was 1.4 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death rates ranged from 13.7 in Perth to 30.9 in Paisley. The zymotic death rate in these towns averaged 3.1 per 1,000. The highest rates being recorded in Paisley and Greenock. The 233 deaths in Glasgow included 26 from diarrhoea, 8 from whooping-cough, 8 from "fever," and 5 from diphtheria. Two fatal cases of diphtheria were also recorded in Edinburgh.

LEGAL NOTIFICATION.

There is a view of the Notification of Diseases Act which is far too much registered at the present time. The tendency is to throw the responsibility of notification upon the doctor and entirely overlook the fact that

it lies equally upon the householder. The medical profession is in fact looked upon as an easy-going beast of burden on whom all such matters may be thrown, while the householder, being a slippery fish, who will always plead ignorance and from whom "costs" and with a perfectly extracted, is allowed to go scot free. We are pleased therefore to be able to record that at the last meeting of the Droxfield District Council it was resolved that public notices should be posted in Sheffield stating that people neglecting to notify infectious diseases would be prosecuted.

CARLISLE WORKHOUSE INFIRMARY.

THE medical inspector, Dr. Fuller, whilst praising the work done by the nurses in the hospital, condemns in no measured terms the accommodation provided in the hospital. The sum and substance of what he says is that the structure is antiquated, the wards admitting of no classification; there is no maternity department, no wards for children; the pressure on the space is in excess of requirements for ventilation or management; the nurses' quarters are insufficient; the nursing administration is defective. After reading this we are glad to see that the question of the extension of the hospital is under the consideration of the Board, and we hope that this will result in a new building and not in another example of patching, so cheap in the present, so costly in the near future.

NIGHT-NURSING AT THE COVENTRY WORKHOUSE.

WE fail to understand the motives that influenced the action of the ten members who voted against the motion to appoint a night-nurse in the above workhouse; the resolution as moved by Mr. Stevens was emphasised by the report of a case of ill-usage by an inmate in charge of the ward, and by the fact that many deaths occurred in the infirmary during the winter, a large proportion at night. The discussion was very warm, the stock phrases—no complaints of neglect; why make a change? only infirm and chronic patients to wait on, and the like—being freely thrown about. Ten men—for we note with pleasure that none of the lady guardians supported the inhuman vote—carried their way against eight who were in favour of this necessary addition to the nursing staff.

THE BELFAST CORONER'S JURY ON THE TREATMENT OF EPILEPTICS.

AT an inquest held on the death of an epileptic in the above workhouse the jury appended to their verdict the rider "that in their opinion epileptic patients should be treated apart from lunatics, and that the association of epileptics with lunatics not only retarded their progress but accelerated their death; and further said that in their opinion lunatics in workhouses should be sent to properly equipped lunatic asylums." The treatment, or rather absence of treatment, of these unfortunate in the Irish workhouses is a matter which demands immediate attention on the part of the central authority, and we trust that every means will be taken by the press and the medical profession to draw public attention to the misery of these unhappy lunatics all over the country.

THE BISHOP AUCKLAND BOARD OF GUARDIANS.

WE noted in the BRITISH MEDICAL JOURNAL of September 14th, page 650, the fact that this Board had declined to act upon the report of its own Committee, which recommended an increase of salary to the medical officer, on the ground that his work and responsibility had enormously increased and that the office was considerably underpaid. We see by the *Newcastle Leader* that Dr. Wardie, the medical officer in question, has written to the guardians, expressing his astonishment that the Board declined to accept the recommendation of the Committee. Dr. Wardie stated as a fact that his remuneration was on a scale of two-thirds only of that paid to the barber for occasionally shaving the patients, and he found it impossible to believe that any true guardian of the poor could deliberately wish such a system to be continued. The decision of the Board seems to point to this not being altered for six months at least, unless the Local Government Board take the matter completely out of the hands of the guardians, and this we hope to see done. It is very evident that this Board must be influenced by some higher authority, as other matters which they are supposed to control appear to require immediate attention. The placing of 30 inmates in quarters only adapted for a smaller number—namely, 18—is a matter which can no longer be permitted when once this fact is before the public.

THE STATUS OF MEDICAL OFFICERS OF HEALTH.

MR. ELLIOT DAUNT, D.P.H., advocating the exclusion of medical officers of health from private practice, writes:

Of course this would entail a considerable increase in the money spent by local authorities in giving adequate remuneration to the officers in question, and doubtless I shall be met by the remark that in these days of heavy taxation, the local rates could not stand such an increase. But, is it on any grounds whatsoever fair or equitable, that any local authority should have to bear the burden of the expense attending this branch of the profession, which, while it doubtless confers great benefits on their district, is doing a work which, nevertheless, confers a service, not second in importance on the country at large? I think not—and it is not at all true—that the whole work and expenses attending it should be contracted and paid for by the State? I have little doubt that it is because public authorities take their views that they give the medical officer of health's claim down to a mere pittance, and allow him to court and engage in private practice.

Something further is necessary on the part of the Legislature to place the efficient working of such essential duties as the medical officer of health has to perform on such a sound footing that the country as a whole shall have the full benefit of this highly important work, and I must strongly advocate that all duties connected with public health should be under the direct and supreme control of the Medical Department of the Local Government Board, and that all professional men engaged in such work should belong to a staff attached to that department, and paid by the Imperial Exchequer. Were this

no, all appointments to the various districts, whether rural or urban, would be made by them and without the interference from any of the existing sanitary authorities. The duties of the medical officer of health would be defined as now, by the Public Health Acts and by the by-laws in force in the several districts; and while the authority under whose control the medical officer of health would work would be the Local Government Board only, he would, of course, work in union with the various sanitary authorities. It is by such a system alone that the work of public health reform can ever be thoroughly accomplished, and the extra burden on the Exchequer would be money well spent. Of course, to bring about this change an Act of Parliament would be necessary, but there is ample time to get it done during the session of 1896. I shall be pleased to go further into details of the scheme with any of your numerous readers.

CRITICISM OF NOTIFICATION CERTIFICATE.

OFFICER OF HEALTH writes: A is a legally-qualified practitioner, and was called to see some children, when he found they were suffering from scarlet fever. He then reported the cases to the officer of health for the district in which the cases existed. It is a medical man, and is also a member of the district council whose officer had received the notification, and at one of their meetings stated he had seen the cases reported by A., and that he found they were not scarlet fever, and that A. had only reported for the sake of the 2s. 6d. fee. Will you say whether the statement is not inconsistent with his duties as a councillor—although he may have been acting according to his belief—and whether such a statement is not libellous and therefore actionable at law? Is it not settled that the notification as sent by a medical man must be accepted by the officer of health, and he himself must take it as certified?

. Whether the words used were actionable or not under the circumstances we cannot undertake to say, but there seems to be no room for doubt that they were unwarranted, and the occasion chosen for their utterance does not lessen the offence. A notification is an expression of professional opinion not to be lightly controverted, and only under exceptional conditions would even the medical officer of health to whom it is sent be justified in questioning it. These conditions do not extend to members of public bodies as such, medical or otherwise, and a public attack on the part of one medical man upon the good faith of another is a matter which calls for earnest protest.

CLUB PATIENTS AND NOTIFICATION FEES.

MEMBER wishes to know what is the fee payable for notification of infectious disease in the case of club patients.

. This is one of the many points which the Notification Act fails to make clear. In the absence of any authoritative decision, club patients may be assumed to rank in this respect as private patients, in which case the notification would carry the full half crown fee.

NOTIFICATION OF INFECTIVE DISEASE.

ENQUIRER asks for replies to the following questions:

1. Is transmission of the disease certificate by post a sufficient fulfilment of the provision that notice be given to the medical officer of health "forthwith"? (This in a town of over 50,000 population, with several deaths daily.)

2. Can the medical officer of health insist on the certificate being sent by special messenger immediately. If so, who should bear the expense, the sanitary authorities, the doctor notifying, or the householder?

3. Is the fee of 2s. 6d. paid for "early information" or is it meant to cover expense of special messenger or of postage, or is it simply the remuneration due to the doctor notifying for his written expressions of opinion that the disease is what he certifies it to be?

4. Where can a copy of the Act relating to infectious disease and its notification be obtained or consulted?

. 1. Yes.

2. No.

3. For the written expression of opinion, with the further conditions that it is to be given to the medical officer of health, and "forthwith." The post is regarded as a sufficiently speedy mode of communication, and the trifling cost of postage may reasonably be paid by the notifier who elects to make use of it.

4. The Infectious Disease (Notification) Act may be obtained at a cost of a few pence from any Parliamentary bookseller; but some few towns derive their notification powers from local Acts. There would probably be no difficulty in obtaining full information either at the health office or from the Town Clerk.

THE BERTILLON SYSTEM IN ACTION.—At the trial of a burglar at the City of London Sessions this week the Bertillon anthropometric system came into action for the first time in this country. The prisoner after conviction denied his identity with a burglar who had been convicted four times before. The measurements, however, and the thumb and finger marks, taken in July last when he had been discharged on a ticket of leave, corresponded exactly, leaving no doubt of the burglar's identity.

INDIA AND THE COLONIES.

INDIA.

It has been decided, says the *Times of India*, that the Boards of Survey on largest expenditure, roads, water, etc., are to be composed of medical officers, but when the number of medical officers present at a station will not admit of this being done, the Board may, at the discretion of the officer commanding the station, be composed of military and medical officers, with a medical officer as president, or solely of military officers with a medical officer in attendance.

NURSING IN THE NATIVE HOSPITALS OF BOMBAY.—A fund has been started for nursing the native hospitals of Bombay, and certain influential persons have subscribed. As yet, says the *Times of India*, no Hindu or Mussulman gentlemen have done so, but as the members of these communities most largely benefit by the hospitals, it is expected that there will be no difficulty in getting them to give to the fund. Lord Sandhurst has kindly promised his assistance to the matter, and most probably a meeting will be held later with the object of advancing the scheme, at which he will preside.

ANKYLOSTOMIASIS IN CEYLON.—In a paper on ankylostoma duodenale, read at the Indian Medical Congress, 1894, Dr. H. Thornhill supplies some very interesting information concerning the prevalence and importance as a disease factor of that parasite in Ceylon. So prevalent is ankylostomiasis in this island, that he regards it as second only to malarial fever as a destroyer of life and labour, and he advocates the institution of vigorous measures for restricting its ravages. He supplies some excellent hints on prevention and treatment. His remarks on the mode of administration and the dangers of thymol should be borne in mind by everyone who essays to use this useful, but when incautiously used most dangerous, drug. He says: "I would wish to add a word of caution regarding the administration of thymol in spirituous solutions, and as to the giving of brandy or spirits shortly after its administration. One of the fatal cases was a man who had received 30 grains of thymol suspended in water at 7 A.M. He experienced no special symptoms after it, and at 4 P.M. the nurse gave him the second dose of 30 grains. As this man was supplied with arrack as an extra, and as in such cases a portion of the arrack was usually given at 9 A.M., the nurse gave it to him just after giving the second dose of thymol. The result was that intense collapse set in almost at once, and notwithstanding all efforts the man died within twenty-four hours, the collapse manifestly being due to the arrack dissolving the thymol, which was thus absorbed." Some time ago we reviewed in these columns a work on African diseases, in which the author actually recommended the administration of this drug in spirituous solution. It is to be hoped that his recommendation has not been acted on. Dr. Thornhill seems to prefer male fern to thymol. Of the former he says: "Male fern is certainly a most disagreeable medicine, but my experience is that it is less objected to than thymol, and that the giddiness, fainting, vomiting, and collapse which it produces are milder and far less frequently produced by it than by thymol." He mentions oil of pepper, kerosene oil, and carbonate of guaiacol as possibly effective, less dangerous, and more agreeable substitutes for thymol or male fern.

WESTERN AUSTRALIA.

THE CUE HOSPITAL.—We have received a voluminous correspondence in regard to the management of the Cue Hospital. Without entering in detail into the numerous changes which have been made, we may say that although traces of personal animus are not difficult to discover, it is clear that there have been defects and irregularities both in the administrative and the professional departments. It is to be hoped that the exhaustive report of the inquiry into the management of this hospital, which has been made by Dr. Giles, Royal Commissioner, and was laid on the table of the House of Representatives on August 2nd, will have the effect of introducing into its administration much-needed reforms.

SANITATION OF CALCUTTA.—Dr. Simpson, the medical officer, in a recent report to the Calcutta Municipality, bitterly complains that Mr. Baldwin Latham's recommendations as to the sewerage have been neglected. It seems that the outfall is obstructed by tidal influence, and there is serious pollution of the soil, owing to leakage. The result is that the death-rate is leaping up alarmingly. It is certainly of little use to secure the advice of an expert like Mr. Latham, and then to neglect to follow it. At Bombay the medical officer also addresses a plaint to the Municipal Council as to their sloth in carrying out reforms. He demands immediate attention to such details as disposal of refuse, the connection of buildings with sewers that have been built years ago, surface drainage, prevention of waste of water, and the abatement of overcrowding. The drainage engineer finds the greatest difficulty in keeping the sewers clear, owing to the want of water for flushing purposes, while all the time the soil is being converted into swamps, owing to waste. There is no doubt about it—the municipalities of our great Eastern empire requires a good deal of stirring up.

DR. JOHN SYER BRISTOWE. Consulting Physician to St. Thomas's Hospital, who died on August 20th last, has left personal estate valued at £15,734 2s. 3d. He appointed as sole executrix his wife, Mrs. Miriam Isabella Bristowe, and left to her all his real and personal estate absolutely.

MEDICAL NEWS.

THE DISTRIBUTION OF PRIZES AND THE PRESENTATION OF THE HANBURY GOLD MEDAL BY THE PRESIDENT OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN will take place on October 2nd, at 3 p.m., and Professor F. T. Roberts, M.D., F.R.C.P., will deliver the inaugural sessional address.

PENSION TO A POOR-LAW OFFICER.—At the meeting of the Camberwell Board of Guardians, held on September 4th, Dr. Partridge moved: "That Dr. Herbert Chabot, medical officer of the infirmary, having resigned his appointment on account of permanent infirmity of body, after twenty-one years' service, a superannuation allowance be awarded him, and that three years be added to his period of service, such superannuation allowance to be £200 16s. per annum, subject to the approval of the Local Government Board." The motion was carried by 17 against 1.

RETREATS FOR INEBRIATES IN AUSTRIA.—The Austrian Government has prepared a Bill for the treatment of habitual drunkards. The measure proposes to empower the authorities of the State, the provinces, the districts, and of the various towns or communes severally to open retreats for inebriates. Those who enter voluntarily will not be able to leave at will, but are to be treated exactly like the compulsory inmates. The term of detention will be generally for two years, but the inebriate may be released on leave after one year, but he should be confined again in case the trust reposed in him should prove to have been ill-placed. After the two years' term he must be released, but if he should afterwards come under the provisions of the measure he may be sentenced again and again for fresh terms of two years, and eventually given over to a lunatic asylum or to a hospital, as the case may require.

MILLIONAIRES' CHARITIES.—Mr. Barnato has just devoted £2,000 to the endowment of two cots in the children's ward of the Kimberley Hospital; £3,000 have been put in trust for the endowment of three annual scholarships of £50 each for boys connected with any school in the Diamond Fields. Johannesburg owes to Mr. Barnato the public school intended for the children of the poor, to which he has devoted £10,000 to be expended in building and providing an efficient staff of teachers. All such generous gifts are, however, belittled by the unprecedented donation of 2,000,000 dollars by Mr. J. D. Rockefeller to the Chicago University. Mr. Rockefeller's fortune is said to have reached the enormous figure of 150,000,000 dollars, namely £30,000,000. One of his daughters is married to Mr. Charles Strong, Professor of Psychology in the Chicago University, hence his interest in this, the youngest of America's universities. Never has mind more successfully influenced money.

OPERATIONS ON WILD ANIMALS.—To the existing list of operations on wild animals in menageries must now be added one on a lion. Many years ago Mr. White Cooper couched the white bear for cataract, and Mr. Ernest Hart removed the eyeball of the emu in the Zoological Gardens in London. From Chicago now comes the story of an inflamed molar being extracted from the jaw of the lion known as "Major" in the Lincoln Park Menagerie. The legs of the lion were secured by ropes, a stout stick was thrust into his mouth, and his jaws held open by strong cords. Veterinary Surgeon Burns poured chloroform down his throat till the lion lay quiet, and with an immense pair of forceps, said to be 2 feet long, the inflamed molar was successfully extracted.

THE CHOLERA.—According to a telegram from Odessa, Asiatic cholera is spreading so seriously in the South-Western Provinces, that the Government has opened additional cholera barracks near the railway stations at Petchanokva, Krivin, Edolbounovo, and Dunbo. Several doctors and nurses have been ordered to those places. The regiments now stationed in the parts worst affected have been ordered to Jitomir. In the Province of Volhynia there were 2,497 cases of cholera and 941 deaths from August 18th to August 34th, and 3,353 cases and 1,190 deaths from August 26th to August 31st. In the Province of Podolia 34 cases and 20 deaths occurred from August 21st to August 24th, and 67

cases and 25 deaths from August 25th to August 31st. Cholera has broken out among the natives at Honolulu. Forty cases and 31 deaths occurred between August 18th and September 4th. Eight fresh cases of cholera and 6 deaths were reported at Tangier on September 11th. Six fresh cases of cholera and 9 deaths were registered at Tangier on September 17th.

CENTENARIANS.—Mrs. Margaret Anne Neve, a resident in Guernsey, who has just celebrated her 103rd birthday, has always led an active, busy life, and even now she works in her garden every day for an hour and a-half, and reads for some time. She is an accomplished linguist, and understands French, German, Italian, Spanish, and Greek. In earlier life she was a great traveller, and when 92 years of age she went on a journey to Cracow in Poland, to see Kosciusko's monument, accompanied only by her sister, who was 89. In Cabul there is said to be an old woman 140 years of age. Her age is computed by the number of Ameers she has known. This old lady is a favourite with the present Ameer, and she often goes to Court to amuse the King with stories of his ancestors. She has double cataract, and the Ameer was anxious that Miss Hamilton, M.D., should operate on her before she came to England in the suite of the Shahzada, but the matter was wisely deferred.

MEDICAL VACANCIES.

The following vacancies are announced:

- BELGRAVE HOSPITAL FOR CHILDREN.** 77 and 79, Gloucester Street, S.W.—House-Surgeon. Board, fuel, and lights provided. Applications, endorsed "House-Surgeon," to the Honorary Secretary at the Hospital by September 28th.
- BETHLEM HOSPITAL.**—Two Resident Clinical Assistants; doubly qualified; appointment for six months. Apartments, ration, washing, and attendance provided. Applications, endorsed "Clinical Assistantship," to the Treasurer at Bethlem Hospital before October 1st.
- BIRMINGHAM AND MIDLAND EYE HOSPITAL.**—Assistant House-Surgeon. Salary, £50 per annum, with apartments and board. Applications to the Chairman of the Medical Board by September 30th.
- BRIGHTON THROAT AND EAR HOSPITAL.** 23, Queen's Road, Brighton.—Non-resident House Surgeon. Salary at the rate of £85 per annum. Applications to the Secretary by September 30th.
- CARMARTHENSHIRE INFIRMARY.**—Resident Medical Officer, unmarried. Salary, £100, with board, lodging, and washing. Knowledge of Welsh desirable. Applications to B. Spivoy, Secretary, Barns Row, Carmarthen, by September 28th.
- CARNARVON JOINT SANITARY DISTRICT.**—Medical Officer of Health, must be between 25 and 40 years of age, doubly qualified. Must devote his whole time to the duties, and have a knowledge of the Welsh language. Appointment for five years. Salary, £204 per annum, inclusive of all expenses, except those incurred for such books, stationery, and apparatus required in the performance of the duties. Applications, endorsed "Application for Office of M. O. Health," to J. H. Thomas, Clerk, to the Joint Committee, 14, Market Street, Carnarvon, by October 15th.
- CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.**—Junior House-Surgeon, registered and unmarried. Honorarium, £60 per annum, with board, lodging, and washing. Applications, with not more than three recent testimonials to the Honorary Secretary, Clayton Hospital, Wakefield, by September 28th.
- COUNTY OF BRECON.**—County Analyst. Retaining fee, £48 10s., and a fee of 10s. 6d. for the analysis of every sample. Applications to H. Edgar Thomas, Clerk to the County Council, County Hall, Brecon, by October 2nd.
- DURHAM COUNTY ASYLUM.**—Junior Medical Officer. Salary, £100 per annum, with board and lodging. Applications, with not more than three recent testimonials, to the Superintendent, Durham County Asylum, Winterton, Ferryhill, by September 28th.
- DURHAM COUNTY HOSPITAL.**—House Surgeon; doubly qualified; appointment for two years, but eligible for re-election. Salary, £200 per annum, with board and lodging. Applications to V. K. Cooper, Honorary Secretary, 16, South Bailey, Durham, by September 27th.
- ESSEX AND COLCHESTER HOSPITAL.**—House-Surgeon, doubly qualified. Salary, £100 per annum, with board and lodging in the Hospital. Applications to the Committee by October 15th.
- GENERAL HOSPITAL, Birmingham.**—Two Assistant House-Surgeons, must possess a surgical qualification. Appointment for six months. No salary, but residence, board, and washing provided. Applications to Howard J. Collins, House Governor, by September 25th.
- GLASGOW MATERNITY HOSPITAL.**—Obstetric Physician and Assistant Obstetric Physician. Applications to Arthur Forbes, Secretary, 164, Buchanan Street, Glasgow, by November 8th.
- JAFFRAY MEMORIAL BRANCH OF THE GENERAL HOSPITAL, Gravelly Hill, near Birmingham.**—Resident Medical Officer, doubly qualified. Salary, £250 per annum, with board, residence, and washing. Applications to Howard J. Collins, House Governor, General Hospital, Birmingham, by September 25th.
- LONDON FEVER HOSPITAL, Liverpool Road, Islington, N.**—Assistant Resident Medical Officer. Salary, £100 per annum. Applications to the Secretary by October 1st.

LONDON HOSPITAL, Whitechapel, E.—Medical Electrician, must be qualified and registered under the Medical Act. Applications to G. Q. Roberts, House-Governor, by October 15th.

NORFOLK AND NORWICH HOSPITAL.—Dispenser; must be registered Pharmacist. Salary, £100. Applications to the Secretary by October 1st.

PARISH OF BURNES, Sutherlandshire.—Medical Officer. Guaranteed salary, £150 per annum, with practice, free house, and garden. Applications to Robert Sutherland, Inspector of Poor, Burnes, by October 10th.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone Road, N.W.—Resident Medical Officer. Appointment for four months. Salary at the rate of £60 per annum, with board and residence. Applications to the Secretary by September 23rd.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Doubly qualified, and registered. No salary, board, lodging, and washing. Applications and testimonials to the House-Surgeon by October 1st.

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke Road, Brighton.—House Surgeon; doubly qualified. Salary, £80 per annum, with board, lodging, and washing; no stimulants. Applications to the Chairman of the Medical Committee by October 6th.

SAMARITAN HOSPITAL FOR WOMEN, Nottingham.—Junior Surgeon. Applications to the Honorary Secretary, J. A. Simpson, Solicitor, South Parade, Nottingham, by October 1st.

SUSSEX COUNTY HOSPITAL, Brighton.—Assistant House-Surgeon, doubly qualified, unmarried, and when elected under 30 years of age. Salary not exceeding £90 per annum, with board, washing, and residence in the hospital. Applications to the Secretary by October 2nd.

THORNTON URBAN DISTRICT COUNCIL.—Medical Officer of Health. Salary, £87 per annum. Applications to Raywood M. Stansfeld, Clerk to the Council, by September 23rd.

WEST LONDON HOSPITAL, Hammersmith Road, W.—House-Surgeon. Appointment for six months. Board and lodging provided. Applications to R. J. Gilbert, Secretary-Superintendent, by September 23rd.

MEDICAL APPOINTMENTS.

ADAMS, Dr. J., reappointed Medical Officer of Health to the Runcorn Rural District Council.

ADDENBROOKE, E. H., M.R.C.S.Eng., reappointed Medical Officer of Health to the Kidderminster Rural District.

BATTIE, E. Wharmby, M.R.C.S.Eng., L.R.C.P.Lond., appointed House-Surgeon to the Manchester Royal Infirmary.

BURTON, C. Kelly, M.B., M.C. Edin., appointed Senior House-Surgeon to the Cumberland Infirmary, Carlisle.

CHARPENTIER, A. E. L., M.D. Durh., L.R.C.P.Lond., appointed Medical Officer for the Uxbridge District of the Uxbridge Union, *vice* W. Rayner, M.R.C.S.Eng., deceased.

CLARKE, Dr., appointed Medical Officer for the Aston District of the Rotherham Union.

GRAN, R. D., M.R.C.S.Eng., L.R.C.P.Lond., appointed House-Surgeon to the Manchester Royal Infirmary.

DAWSON, W. E., L.R.C.P.L., L.M., L.R.A., appointed Admiralty Surgeon for Walton-on-the-Naze and Handford Waters.

DOUGNEY, William, L.R.C.P., L.R.C.S.Eng., appointed Medical Officer for the No. 7 District of the Kingsbridge Union, *vice* O. Eaton, L.R.C.P.Lond., M.R.C.S.Eng., resigned.

EVANS, William O., L.R.C.P., L.R.C.S.Eng., appointed Medical Officer for the No. 1 District of the Hawarden Union, *vice* A. L. Evans, L.R.C.P.Lond., M.R.C.S., deceased.

FITCH, Frederick, M.D. & Ind., M.R.C.S.Eng., reappointed Medical Officer of Health to the Kidderminster Rural District.

GREENHALGH, John, L.R.C.P.L., L.M., appointed Medical Officer for the Fylinglades District of the Whitby Union, *vice* G. H. Carrington, M.R.C.S.Eng., resigned.

HALL, J. P., M.B., Ch.B. Vict., M.R.C.S.Eng., L.R.C.P.Lond., appointed House-Surgeon to the Manchester Royal Infirmary.

HARCOURT, G. R., M.R.C.S., L.R.C.P.Lond., appointed Assistant Medical Officer at the Lambeth Union Infirmary.

HASWELL, N. Richard, M.R.C.S.Eng., L.S.A., reappointed Medical Officer of Health to the Helston Rural District Council.

HILLIER, R. J., M.R.C.S., L.R.C.P.Lond., appointed Senior House-Surgeon to the West Ham Hospital, *vice* S. R. Blake, L.R.C.P., L.R.C.S.Eng., resigned.

KENNY, J. D., M.D. & U.L., M.Ch., appointed Medical Officer for the Treton District of the Rotherham Union.

LINDS, Theodor, M.D. Edin., appointed Medical Officer for the No. 5 District of the Westbury-on-Severn Union, *vice* N. F. Searanoke, L.R.C.P. Edin., M.R.C.S.Eng.

MCDUGALL, Alexander H., M.R.C.S., L.R.C.P.Lond., appointed Medical Officer of the Birmingham Parish Workhouse.

MYNTER, Leonard J., M.D. Brux., M.R.C.S., appointed Medical Officer to the Uxbridge Union Workhouse, *vice* W. Rayner, M.R.C.S.Eng., deceased.

MOORE, F. C., M.Sc., M.B., Ch.B. Vict., appointed House-Surgeon to the Manchester Royal Infirmary.

MORSE, Edward, L.R.C.P., L.R.C.S.Eng., reappointed Medical Officer of Health to the Torrington Town Council.

NUNNS, Herbert FitzStephen, M.R.C.S., L.R.C.P.Lond., appointed Medical Officer of the Clun District of the Clun Union.

PARTRIDGE, Samuel, M.R.C.S.Eng., L.S.A., reappointed Medical Officer of Health to the Darlaston District Council.

FRANCE, John P., M.R.C.S., reappointed Medical Officer of Health to the Lowest Town Council.

PICKERING, Dr. George W., appointed Medical Officer for the No. 9 District of the Hexham Union.

PINNINGTON, Walter Augustus, M.R.C.S., L.R.C.P.Lond., appointed Medical Officer for the No. 6 District of the Brighton, Hove, and Preston Provident Dispensary, *vice* J. H. Humphreys, M.D. Lond., resigned.

REYNOLDS, H. D., L.R.C.P. Edin., M.R.C.S.Eng., reappointed Medical Officer of Health to the Penrith Rural District Council.

ROBERTS, Edward H., L.R.C.P., L.R.C.S.Eng., appointed Medical Officer for the No. 1A District of the Hawarden Union, *vice* A. L. Evans, L.R.C.P.Lond., M.R.C.S., deceased.

ROUSE, E., L.R.C.P. Edin., M.R.C.S.Eng., reappointed Medical Officer of Health to the Bideford Rural District Council.

SANDFORD, H. V., L.R.C.P.Lond., L.F.P.S. Glasg., reappointed Medical Officer of Health for Horncroftshire.

SHARMAN, Mark, M.B. Glasg., M.R.C.S.Eng., appointed Divisional Surgeon to the Herts County Constabulary.

SKINNER, E. W., M.D. Edin., reappointed Medical Officer of Health to the Rye Rural District Council.

SPURHILL, Charles, F.R.C.S. Edin., L.R.C.P.Lond., appointed Medical Superintendent to the Poplar and Stepney District Sick Asylum, *vice* W. H. Pearce.

STEEN, R. H., M.B. Lond., appointed House-Physician to St. Mary's Hospital, W.

SWAINSON, J. A., M.R.Cantab., L.R.C.P., L.R.C.S., L.M. Edin., L.F.P.S. Glasg., appointed House-Surgeon to the Hulme Dispensary, Manchester.

SYLVESTER, Kirwan F., L.R.C.P. Edin., M.R.C.S.Eng., appointed Medical Officer of the Melksham Union Workhouse, *vice* G. M. Sylvester, M.R.C.S.Eng.

TAGGART, J. Scott, M.B., Ch.B. Vict., appointed House-Physician to the Manchester Royal Infirmary.

THOMSON, Dr., reappointed Medical Officer for the Buckland Brewer District of the Bideford Union.

TUXFORD, James E., L.R.C.P., L.R.C.S.Eng., appointed Medical Officer of Health to the Boston Town Council, *vice* Walter Clegg, M.R.C.S., resigned.

YOUNG, Chambre C., M.B., B.C. Camb., appointed Medical Officer for the No. 5 District of the St. Columb Major Union, *vice* N. A. Norway, M.R.C.S.Eng., L.R.C.P.Lond., resigned.

WASHINGTON, R. J., M.R.C.S.Eng., L.R.C.P.Lond., appointed House-Physician to the Manchester Royal Infirmary.

WEDDER, H. W., M.D., M.S. Lond., M.R.C.S.Eng., appointed Second Medical Officer to the Provident Department of the Plymouth Public Dispensary.

WILKINS, Dr., appointed Medical Officer for the Third Liskeard District of the Liskeard Union.

WILKINSON, J., M.B., C.M. Edin., appointed Medical Officer of Health to the Boston Rural District Council, *vice* Walter Clegg, M.R.C.S., resigned.

WOOLRIGHT, A. Philip, L.S.A. Lond., appointed Junior House-Surgeon to the West Ham Hospital.

YOUNG, A. G., M.B., appointed Medical Officer for the Rillington District of the Norton (Out-Relief) Union.

DIARY FOR NEXT WEEK.

TUESDAY.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 3 P.M. Lecture at 4.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

BENJAMIN.—On September 17th, at The Old Hall, Dorrington, near Shrewsbury, the wife of J. K. Kinsman Benjamin, M.R.C.S.Eng., L.R.C.P.Lond., of a daughter.

HILL.—On August 2nd, at the Church Mission Hospital, Pak-Hoi, South China, the wife of Leopold G. Hill, M.R.C.S.Eng., L.R.C.P.Lond., of a daughter.

MARRIAGES.

HARRIS—HOWE.—On September 11th, at St. John's Church, Monkstown, by the Rev. S. W. Howe, brother of the bride, assisted by the Rev. H. Hawkins, William James Harris, M.B., M.A., F.R.C.S., of Shaftesbury, Dorset, to Kathleen Emily, eldest daughter of the late Lieutenant-Colonel Wm. Howe, of Monkstown, co. Cork.

EMPTON—HALLEY.—At Broomhall, Broughty Ferry, N.B., on September 12th, by the Rev. Lewis A. Muirhead, St. Luke's, Broughty Ferry, assisted by the Rev. W. Lewis Robertson, M.A., St. Thomas Free Church, Greenock, Surgeon-Major R. J. S. Simpson, Army Medical Staff, to Jane Mary, elder daughter of George Halley, Merchant, Dundee.

THOMSON—BENNETT.—On September 12th, at St. Clement's, Bourne-mouth, Mulville Thomson, Manvers House, Bradford-on-Avon, Wilts, to Mary, eldest daughter of the late Edward J. S. Bennett, Esq., J.F., of Cobham, Surrey, and Inglestone, Hants.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 49, Strand, W.C., London; those concerning business matters, non delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 49, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 49, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

TRICRY, M.D., would be glad to know the best way to improve and strengthen the growth of hair in young healthy children.

REKORAT would like to know if it is possible to obtain on hire and terms a battery such as recommended in Dr. Geo. Herschell's work on *Intoxication*.

M.B. LOND. would be glad of a list of the most suitable works to read for the "Mental Physiology" examination of the London M.D. He has plenty of time and does not wish to "cram" the subject.

HOMER FLESH asks to be recommended a book on the more common defects in horses, not one to do away with the services of the veterinary surgeon, but to enable one to pick out a horse that would be worth going before a veterinary surgeon.

MR. JAMES H. DAWK, M.B. (Westcott) asks whether there is any institution in Bath where a lady patient with limited means suffering from chronic rheumatism and who is quite incapable of walking could be received for a course of baths at a payment of about 30s. to 50s. a week inclusive.

STORAGE OF RAIN WATER.

DR. J. H. POTTER (Forlock) writes: Should rain water stored in tanks for drinking be exposed to the air or covered in? Is galvanised iron and cement suitable for such storage? What is the least expensive and efficient filter for separating as it flows from tank any soot or sand that may be in suspension? Lastly, where can the apparatus be procured which prevents the first rain washings of the roof from entering the tank?

INDURATED SCAR AFTER BURN.

SAR asks for advice in the treatment of the following case: Four months since I was sent for to a child who had fallen into the fire and burnt the anterior portion of his right thigh. I treated him with canthar oil, and subsequently ung. zinc, and he made a good recovery. Yesterday I was called in to see him, and found the greater portion of the scar (some 4 by 5 inches) raised some 1/2 inch from the surface of the skin, red and glazed, very hard to the touch, but no indication of suppuration though somewhat hot. The only information I could get was that the child had been rubbing the place, which had been in this state for some weeks. I ordered cold water dressings to be applied, and should be glad of any further advice.

ANSWERS.

G. W.—It is illegal to practise as a dentist unless registered as a dentist by the General Medical Council. A dental qualification is now necessary before registration is possible. A duly qualified medical man can practise as a dentist upon the strength of his medical registration.

DR. M. D. O'CONNELL.—The discussion on which Dr. O'Connell desires to enter would be better deferred until Surgeon-Colonel Lawrie's views are authentically published. If Dr. O'Connell could personally communicate with Dr. Patrick Manson (21, Queen Anne Street, W.) he would probably be convinced in five minutes, from actual preparations from malarial blood, that the body under discussion is a genuine parasite, and has nothing to do with white blood corpuscles or their nuclei.

THE COCKADE.

COCKADE.—All commissioned officers of Her Majesty's forces are entitled to put a cockade on their cockade's hat; therefore a surgeon-major is certainly entitled to do so.

BOOKS ON OPHTHALMOLOGY.

IN answer to K. Y., who wishes to study the eye, he should read, as an introduction on the optics, some elementary treatise like Dero's

Elements of Optics. This should be followed by Landolt's work on the *Eye*, and then *Practical Optics* by the late Prof. Dr. H. von Helmholtz. For a treatise like Dero's *Handbuch der Optik* is too large. For a treatise on the best of the smaller books are Swanwick and Nettleship's and of the larger ones Dero's and the translation of Fuchs's textbook are very good.

DISSEMINATING CHAMBER.

MR. BETHELL (Medical Officer of Health for the Borough of Bridgworth) writes to us that he has lately had a disseminating chamber erected at a cost of something under £70, and that he will be pleased to give "Z. X. T." any details he may require.

RESIDENCE IN PARIS.

DR. F. W. LYLE (Castle Hill, W.) writes: The admirable project of re-constituting the Ecole College in Paris has never been carried out; under these circumstances M.B. Lyle will find it best to live in the 14th Quarter in the Rue des Ecoles or some of the streets in the neighbourhood of the saint Michel university, in all of which he will find numerous *appartements garnis* to choose from. The Secretary of the Association des Etudiants in the Rue des Ecoles will doubtless be glad to give him all particulars as to classes, clinics, etc.

RESIDENCE IN SOUTH AFRICA.

MR. R. STEVENSON, M.B. (Prince Albert, Cape Colony) writes: In reply to "Q.S." in the BRITISH MEDICAL JOURNAL of July 27th, I may state that the following towns in Cape Colony are large enough to have banks, and, being in the "Karoo," are therefore the best places in South Africa for phthical cases: Beaufort West, Victoria West, Richmond, Willowmore, Murraysburgh, Oudshoorn, Cradock, in the Eastern Province, is also an excellent place, and so is Bloemfontein in the Orange Free State.

HYPODERMIC TREATMENT OF SYPHILIS.

SURGEON-CAPTAIN W. S. FRIDMORE, I.M.S. (2nd Burma Battalion, Mandalay) writes: In the BRITISH MEDICAL JOURNAL of June 30th, under "Queries," "C. I. K." asks for information relating to hypodermic medication in syphilis. He will find a paper referring to the subject in the Army Medical Department Report for 1893. Surgeon-Major Love, M.D., A.M.S., Station Hospital, Darjeeling, in 1894 gave the treatment a fair trial with great success. He says: "I am satisfied that this method of administering mercury is followed by better results than any other method." The prescription he used was as follows: R Hydragr. 5j; lanolin, 3ij; ol. oliv. 5ij. The olive oil should be sterilised by heat, allowed to cool, and then the three ingredients should be rubbed up in a mortar for from two to four hours. Surgeon-Major Love's method is to inject six of this paste the first time, and also the second if the disease is recent and of a virulent type; afterwards to inject every week till the disease has disappeared or the gums become spongy. The needle should be inserted to the full into the muscles of the hip. I hope shortly to communicate the results of my own experience. At present I have not treated a sufficient number of cases to enable me to come to a conclusion.

NOTES, LETTERS, ETC.

ERRATA.—In Dr. J. G. Robertson's letter headed "An Obscure Case of Hematuria," which was published in the BRITISH MEDICAL JOURNAL of September 14th p. 691, for "hematuria," in the fourth line, read "hematuria."—In Dr. George Oliver's paper on "The Therapeutic Employment of the Suprarenal Glands," in the BRITISH MEDICAL JOURNAL of September 14th, on page 691, column 2, 2 lines from top, read "muscular tenacity" for "muscular tension," and on page 691, column 2, second line from foot, read "disturbing effects" instead of "distracting effects."

A BEGGING LETTER IMPOSTOR.

DR. D. B. LONG (York) writes: May I state through your columns that it has come to my knowledge that a certain individual, unknown to me, has been sending begging letters signed with my name to various medical men, stating that I have been suffering from nephritis and albuminuria, and am in straitened circumstances, and asking that money should be sent to me at Great North, Essex? The whole story is a fabrication, and I hope no one has been taken in by it.

DIPHTHERIA STATISTICS.

W. M. H. writes: In Dr. Dixey's most valuable paper in the BRITISH MEDICAL JOURNAL of August 31st, page 531, should not the average diphtheria deaths for the first 26 weeks of 1895 be compared with those of a corresponding period in former years—namely, 1891, 20.6; 1892, 24.3; 1893, 31.2; 1894, 31.9; 1895, 31.9—and not with 26 weeks?

"W. M. H." We have referred this letter to Dr. Dixey, who writes as follows: "W. M. H." is undoubtedly right in suggesting that the average weekly number of deaths for the first half of any year is more properly compared with the average for a corresponding period of other years than with that for the whole 52 weeks. But my object in the passage to which he refers was to summarise as briefly as possible the general facts of diphtheria mortality since the beginning of 1891. For this purpose it seemed best to give the complete weekly average for each of the four available years, 1891 to 1894, the average for 1895 being added so far as the figures were attainable at the time when my paper was finally put into shape—namely, early in July. Further and more minute comparisons might have been introduced, but would have tended to somewhat unduly lengthen the paper; they can, moreover, be easily supplied from the materials given in the tables. It is, of course, highly probable that the weekly average for the whole of 1895, when we are in a position to record it, will exceed that of the first 26 weeks.

BACTERIOLOGY AND CHEESE.

PROFESSOR CONN'S bacillus No 41 is being applied very extensively in America, and, from all accounts, with great success. At the Biological Laboratory at Long Island, New York, it is being cultivated with the view of supplying it to the dairies and butter factories of the neighbourhood. Its application to butter-making has been attended with great improvement in the industry, and, according to an American contemporary, is revolutionising the business, its introduction into the cream giving it a finer flavour and keeping properties. This is, indeed, practical bacteriology, and, unless our American cousins are very careful, they will run very grave risks of earning the approval of the "anti" party for putting the science to useful ends.

POSTURE IN CYCLING.

AN M.L.C.S., TWENTY-FIVE YEARS CYCLIST gives some useful rules as to the details of relative position of seat, handles, and pedals on the safety bicycle. With the laudable intention of gaining an upright posture many riders raise the handle until they are above the level of the seat, or even of the hips, whilst the seat is placed so low that the knees are never extended. This is a most inefficient and uncomfortable posture, all control is lost over the machine, and no pulling power obtained for the arms. The arms must be straight and the handles so placed that pulling with the arms shall aid the thrust of the leg without disarranging the steering or shifting the rider on the seat. The seat must be far enough back to maintain a steady hold of the driving (fixed) wheel on the road and to place little weight on the front wheel.

The following rules apply to all normal individuals: The seat should be placed over a point about half way between the hub and front rim of the hind wheel. The height of the seat should be such that the point at its lowest point can be easily reached with the ball of the foot, the foot being horizontal: this means full ankle play. The handles should be as far back as a line passing through the main axis of the driving cog (bottom bracket), the hand bar must be wide enough to clear the thighs freely and to carry the arms clear of the sides. The handle bars should be at the level of the seat, or at least in such a position that the arms shall be straight downwards and only slightly in advance of the body. The point of the handle should reach about half way up the thigh when the pedal is at its highest point, but wide enough to avoid forcing the thighs into steering. The only alteration needed to any normal safety cycle in order to secure these positions is that the handle bar should be some inches longer than the general make. The weight of the body should fall exactly upon the tuberosities of the ischia on to the centre of the pads of the seat (Burgess's or similar seat), the thigh not falling to a perpendicular position at the lowest point of the stroke, so that there may be no tendency to slip off the seat forwards: the pads of the seat should be well cupped and not tightly latched.

Long experience shows that these points constitute the most efficient, comfortable, and healthy posture in ordinary road cycling. To the racing man or the "road scorchers" no advice is offered.

THE MEDICAL DIRECTORY.

DR. W. ALLEN STURGEON (Nice) writes: I think it well that attention should be drawn to a new departure on the part of the publishers of the *Medical Directory*. Appended to the customary circular issued to "Practitioners resident abroad," is a note this year to the effect that no particulars other than the name and diplomas will be given of any practitioner who does not become an annual subscriber to the directory. The meaning of this is that anything more than the bare name and diploma will in future be charged for as an advertisement. This is a change of such importance in the management of this valuable directory that I have thought it right to protest by withholding a subscription for the coming year that I was about to make.

"I OUGHT TO HAVE BEEN SENT FOR BEFORE."

A MODERN COUNTRY G.P. writes: I was much amused to see in the *BRITISH MEDICAL JOURNAL* of September 14th the amusing story of Mr. James Gould's, "Why was I not called in before, etc.," and regret to tell you that it is my own cry weekly, if not daily, now in the year 1895, and I expect of a great many general practitioners also. I was not qualified in 1862, but only in the last ten years, and introduced every modern advantage and dressing and remedy into my practice. The average countryman either tries to cure himself by all the quick remedies he largely advertised or procures something from the local chemist, and puts off calling in the doctor until the last minute, often losing valuable time in acute and inflammatory cases, and why? because of the supposed expense. I should like to know if this is the experience of others, and whether instead of being a good joke it is not really a serious calamity.

AN EASY METHOD OF GIVING AN ENEMA.

DR. R. NHALE (South Hampstead, N.W.) writes: At page 608 of the *BRITISH MEDICAL JOURNAL* is the description of a holdfast enema syringe, and certainly it is a very ingenious plan. An easy method, however, of administering enemata is not generally known. If the fluid to be injected be poured into a small decanter with a lipped orifice this can be held between the two fingers of the left hand and the thumb keeping the lower tube of the enema apparatus in place, and all can be easily carried to the bedside or to the closet as wished.

LETTERS, COMMUNICATIONS, Etc., have been received from:

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

Eight lines and under	20	6	0
Each additional line	0	6	6
A whole column	1	17	6
A page	5	5	0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Poste Remise* addressed either in initials or numbers.

SIXTY-THIRD ANNUAL MEETING
OF THE
BRITISH MEDICAL ASSOCIATION.

Held in LONDON July 30th, 31st, and August 1st, 2nd, 1906.

PROCEEDINGS OF SECTIONS.

SECTION OF PSYCHOLOGY.

W. JULIUS MICKLE, M.D., F.R.C.P.Lond., President.

WEDNESDAY, JULY 31st.

THE PRESIDENT'S ADDRESS.

By W. JULIUS MICKLE, M.D., F.R.C.P.Lond.

ABNORMAL FORMS AND ARRANGEMENT OF BRAIN
CONVOLUTIONS.

I.—THE THEME.

I SPEAK of a few points in brain architecture, as manifest in the conformation and relations of folds and fissures of the brain cortex; and they are taken in reference to mental states, and particularly to the stigmata of hereditary mental degeneracy.

Though long pursued, my studies on this subject have been irregular and intermittent, partly because, at necropsies, attention was more potently occupied with the pathological and histological conditions of the brain and of the whole frame; and partly because other work pressed, and the limitations of time were rigid.

The accepted standards of gyral conformation having been meditated on at first, my subsequent studies on the subject were largely independent of the results of other observers; and thus the mind was purposely kept free from prejudice and preconception. For this abstention there were two reasons: First, one's dissatisfaction with some details of the then-accepted standards of convolutional form (to this subject I will recur); and, secondly, and later on, the appearance of a certain doctrine on the brain in relation to criminal anthropology, involving a special ascription of particular deviations from type as being distinctive of criminals; a doctrine which, at the time, appeared to be incorrect as gauged by what I had seen in brains of the insane; a doctrine which has been partially or fully abandoned, since then, by those or most of those who held it in that sense, or were inclined to do so.

II.—ANALYSIS OF NECROPSIES.

The general impressions received in the course of my investigation into convolutional brain architecture having been, in some respects, corroborated, in others modified, by a recent minute analysis of the results of many necropsies—some of them made far back in time—I will touch lightly, and in a brief and summary way, on one or two out of the many points on which this investigation has been instructive to myself, has been a gathering in of new knowledge, a modification of old.

III.—UNSATISFACTORY STANDARDS OF NORMAL BRAIN FORM.

We may take it for granted, and need not tarry to prove, that a different normal standard of brain form obtains in different stages of individual life, in different races of mankind, and, as a logical inference, must obtain also in different ages of the world and epochs of time; for what practically concerns us at the moment is the normal set of standards for modern British brains. The standards of the normal, hitherto chiefly in use and with which I began, were unsatisfactory, defective, incomplete, insufficient in range and even misleading. For their unsatisfactoriness there are several reasons. One is that some of them have been diagrammatic or schematic, thus unduly accentuating some features and minimising or omitting others. Another is that the brains

from which certain figures and descriptions are drawn have been taken from dissecting-room subjects or from patients—most of them "incapables" of various kinds, dying in rate-supported or State-supported institutions—of whose life-history little or nothing is known in many instances; who often are failures in life—waifs and strays—broken fragments of the wreckage of civilisation, the indication of degeneracy and breakdown. And such failures, waifs, and wreckage are they very often—most often, indeed—because of their mental defect or perverted aberrant type of mind, which not infrequently has as its accompaniment sometimes pathological brain change, but sometimes also, or solely, has an abnormal brain development and aberrant gyral conformation. Indeed, knew we their ancestral and life-history fully we would search such subjects for some of the most interesting forms of convolutional deviation from type. And still more would this be the case if, especially in the past and in some countries, dissecting-room subjects have been largely recruited from the criminals dying in prisons and the mentally decayed and defective dying in asylums. Therefore it is not surprising to find that sometimes the brains taken from the sources previously referred to and published as typical, are what I do not hesitate to declare and describe as being brains of deranged or of defective development and utterly misleading if taken as normal. If the blind lead the blind they shall both fall into the ditch; and the ditch to which I refer is not an ancient and musty moat; it is well filled with modern mud. Let us see to it that we be not swamped therein.

And therefore at an early date I had to modify in details what I had learned from the standards in use as representations of normal conformation of brain.

IV.—THEIR FULL SIGNIFICANCE TO BE ASSIGNED TO
OTHER COEXISTING CONDITIONS.

At the threshold we are met by the question how far we may rightly attribute any significance to these deviations of brain architecture in elucidation of the subject of mental defect and disorder. And, if we decide that they do possess a meaning in this relation, we next encounter the inquiry what precisely their significance is. In reference to this there are many fallacies into which we may wander, many pitfalls into which we may stray. To dwell even lightly upon these would occupy the whole of the time available for this address. Therefore, one must be content with bare mention of some of the most important of them, and thus at least take the precaution of guarding against misconception as to the purport, scope, and implications of what will presently be stated.

To begin with, there is a number of conditions to which due weight must be given and their full importance and significance assigned. Such, for example, are: The pathological, brain changes found, both macroscopic and microscopic; the diseases of parts and organs other than the brain; disorders of blood and lymph circulation, with all their possible local and general states and effects; alteration of the blood constitution in itself; addition to the blood of morbid deleterious materials in, of, or derived from food, drink, drugs, and pathogenic microbes; either transitory or diathetic autotoxic states, of abundant multiplicity of form and origin; practical starvation of brain or, again, its perverted nutrition, however brought about; the strain and stress of life, social, affective, occupational; the physiological evolutionary and involuntional crises and changes of the organism. There are also such considerations as the relative size of the brain to the whole body or to standard weight of race and age; the relative proportion of grey and white in the brain; the richness of the grey, its depth—actual as well as relative—its natural minute structure, in a word, the mere important part of the finer architecture of the brain; and finally, the outcomes other than those mentioned in this address of a comparative evolutionary elaboration or evolutionary simplicity of a brain, as the case may be.

Giving due place to all the considerations just mentioned, I conclude that there still remains over a body of evidence as to the existence of particular conditions and details of brain architecture which are indications and marks of low type of brain and mental organisation; of defective and deviating types of brain development, correspondent to de-

fective aberrant types of mental action and of outward conduct.

Within a certain definite range, I find an agreement between brain conformation and clinical psychiatry. I refer to my observations on the brains examined in an institution for the insane. Of these observations a large number were recently subjected to detailed analysis and comparison; namely, those concerning between 200 and 300 cerebral hemispheres. Numerous conditions of mental disease and defect were represented in the persons of the original owners of these brains.

V.—NEW POINTS OF INFERIORITY, OR DEVIATION OF TYPE OF CONVOLUTIONS AND SULCI.

I will now briefly consider some more or less new points of defective or aberrant development of gyres and fissures which I observed; which were new at the very least in the sense that they were not known to me as being noted by others. Recently, searching for prior observations (if any), in publications not previously seen, I found that certain of these points had place in some detailed description or figure of an individual brain, but, like other unheeded details, had not been the subject of special attention.

Of the special points learned from my observations I place in the front rank (1) those with greater claim to anomalous characters; in the second rank (2) those with lesser claim. (1) To begin with the former: (a) In the first place I have found anomalies of the cortical architectural conformation decidedly more frequent in the right than in the left cerebral hemisphere, even after making allowance for the fact that at least according to my observation the normal standards of right and of left cerebral hemispheres differ somewhat between themselves in Man. (b) Another of the points of more general kind expresses itself in irregularity of gyri, and much irregular division and subdivision of them by the unusual aberrant course, depth, length, forking, or reduplication of ordinary sulci or the existence of unusual ones. It is, perhaps, more characteristically marked in the parietal lobe than elsewhere, and especially so in certain forms of mental disease. It is essentially dissimilar not only on the one hand from an inferior type marked by few and simple gyri and sulci, but also on the other from a normal type of highly-endowed brain, rich in folds and anfractuosités.

Coming to the more local points, they are as follows:

The formation of what I have termed a *præcuneolus*. It consists in the superficial insulation or peninsulation of a portion of the quadrate lobule, usually its upper posterior area, triangular or squarish in shape, or its posterior strip: either on the one hand, and as usually occurs, by a forking or by a reduplication of the inner limb of the parieto-occipital fissure, or on the other, as occasionally is the case, by a fissure, chiefly a displaced transverse parietal, cutting through from the upper to the mesial hemispherical surface.

This condition has important relations to the annectent gyres, and the island or peninsula is (usually at least) apparently formed by a depressed and unbending mesially-directed anterior continuation fold of the first external parieto-occipital annectent gyrus.

More or less connected or associated with this quadrate anomaly are some of several aberrant states of both limbs of the parieto-occipital fissure and of the neighbouring annectent gyri, whether superficial or sunken.

The next condition to mention is the close proximity in their somewhat parallel course of the transverse occipital sulcus to the external limb of the parieto-occipital fissure, so that these are only separated from each other by a narrow ridge or very slender fold.

Another is a "reversed occipital operculum," as I term it, in which the simian opercular type is reversed and the occipital lobe takes on somewhat or slightly the aspect of a buttress, a sort of curved abutment, under the beetling brow and backward crest of the parietal. Of course a tendency to a conformation somewhat resembling that of the simian occipital operculum is a deviation from type long ago observed.

Next is an abnormal variant of the normal issue of the deep temporo-parietal annectent gyri and deep temporal fissure from the first temporal gyre; so that the external surface substance of the latter, or a large portion of it, turns from forming part of the lateral aspect of the temporal lobe,

twists sharply, plunges into, and entirely disappears in the Sylvian fissure, and therewith the parallel fissure apparently becomes continuous with the deep temporal fissure, and loses its way in the Sylvian gutter. In such case a variety of aberrant conditions may concern the isolated representative of the true posterior continuation of the parallel fissure, which restarts immediately behind an interrupting, bridging, anastomotic, gyrus fold.

Next are furrows from the Sylvian fissure, ploughed vertically part (occasionally two-fifths) of the way up the middle of the external surface of the central gyri (more often of the posterior one). In some examples these may, perhaps, mark an unusual extent, and somewhat aberrant or less favourite position or duplication of the insulae of the parietal and frontal opercula. (I am less inclined to think they ever may represent duplication of post-central or pre-central fissure.)

(2) Those of less anomalous character are:

The tendency to an irregular, complete (or almost complete) circle of fissures girdling the temporal, parietal, and occipital regions, from temporo-sphenoidal tip back again to the same (parallel; interparietal, or not; external and internal limbs of parieto-occipital; the "stem"; lingual; and collateral fissures).

And I am inclined to attribute some significance to what I term the formation of a *cuneolus*, inasmuch as I find it associated with an aberrant, defective, and inferior type of conformation of adjacent and other parts. It consists of an unusual form of the now sunken superior internal parieto-occipital annectent gyrus, and of the cleft bordering it posteriorly, which last now drives deeply into the cuneus, ploughing off the upper anterior triangular area of its surface. In some examples, indeed, there is what practically amounts to a forking of the internal parieto-occipital fissure. In transition cases between this and the more usual and normal arrangement, the triangular cortical area (*cuneolus*) between the forks is somewhat sunken, lying below, that is to say, externally and laterally to the general mesial surface plane.

And, again, an upper and posterior and irregularly triangular part of the cuneus may be cut off by a transverse occipital fissure, or other and unusually developed fissure, incising the cuneus to the calcarine fissure, or almost so.

The validity, here, of the following, relating to temporal gyri and fissures, is not assured, and judgment on it is reserved; but in brains with marks of inferiority I occasionally found the first temporal gyrus partly divided by fissurets running upward and backward, the first temporal fissure being in segments so disposed, or giving off branches in that direction; and much more often the second temporal gyrus, partly divided by fissurets directed downward and backward, such practically representing the second temporal fissure, or part of it, in a segmented form. Thus the sections of the latter gyrus and fissure are in a direction at about a right angle to those of the former.

Then there are anomalies of the quadrate lobule, other than that already described above; as, for example, its invasion by extra up curves or branches of the calloso-marginal fissure, or it may be much split by vertical or oblique fissures, or may be the area of conjunction of rami of calloso-marginal and parieto-occipital, or of calloso-marginal and transverse parietal sulci. Extraordinary irregularity may mark the quadrate's fissures, which, as well as the parts of the calloso-marginal anterior thereto, may take the most bizarre arrangement. (In one case, with defective history, a subparietal fissure, very low down, completely isolated the fornicatus from the *præcuneus*, until, after being joined by the transverse parietal, it sank into the sinus of the corpus callosum, very near to the posterior border of the *præcuneus*.) The mesial surface above the fissura calloso-marginalis may present an unusual appearance of two distinct tiers of convolutions, and there are other abnormalities relating to that fissure, to the fornicatus, etc., which have hitherto received but little notice.

Again, the parietal gyres, especially the lower tier, may be much and irregularly split and divided by bi- and trifurcation, or by an unusual branching, or by unusual and prolonged extension of fissures, of the first temporal especially; also by irregularity and zigzag state of interparietal fissure, and of unusual fissures, as, for example, a far-descending and

perhaps forking external limb of parieto-occipital fissure, or sulcus intermedius of Jensen, or even transverse parietal or other fissure from the great longitudinal interhemispherical cleft. Important, here, is the first temporal fissure with its abnormally zig-zagging extensive course branchings and spurs, also its numerous anastomoses with many sulci.

Similarly the upper parietal tier may be affected, and one, two, three, or four fissures may partly divide the superior parietal lobe into several gyres running obliquely backward and inward to the hemispherical edge, and thence over the cliff, and often descending more or less on the mesial quadrilateral surface in the abyss of the great longitudinal chasm.

The frontal gyres, particularly the third frontal, may be channelled by fissures, not only by the vertical limb of the Sylvian and by the inferior precentral fissure, but also by an unusual fissure, or more than one, between those two. These occasionally may ascend high up, even to the first frontal fissure or to the great longitudinal. They may send off a backward spur. Occasionally there is a fissure in front of and parallel with an upper precentral fissure; or, again, a far extension of an upward and forward line of the trunk of an inferior precentral sulcus.

The second and third frontal gyri (and partially the first) are sometimes unusually twisted in their forward course so as to trend forward, upward, and inward, taking a diagonal direction as if the two former sought the frontal tip, the last the mesial aspect; a deviant line of direction and oblique thrust of the frontal gyri. Thereafter the frontal convolutions may more than usually be ploughed or subdivided by short fissures directed forward, upward, and inward.

An islet of cerebral cortex is occasionally formed by unusual aberrant forking of principal fissures, the spurs fully reuniting after encircling an islet of cortex; for example, by the central, interparietal, or parallel fissure.

But, besides this, and as previously described by others, large islands of cortex may be insulated by communications of sulci, chiefly of primary ones, that is to say, the shores of the irregular islands are formed by conjunction of several different sulci, of which some may be either supernumerary or unusually developed secondary fissures.

And, besides as in this last, I would redirect attention to several points which have been published by others; as, for example, a false appearance as of two or of three fissures of Rolando, owing to extremely bold definition either of the precentral or of the postcentral fissure or of both. Or, again, for example, the fact that the supero-lateral frontal surface may be divided more or less into four tiers of convolutions. A division into four tiers was one of the departures from type which my early microscopical investigations taught me. But it was published by Benedikt at an earlier date. Inferring from him, I found the division into four tiers to be rather common due to division of the second than of the first frontal gyrus. Some anatomists, indeed, admit a sulcus of the second frontal gyrus, and an abnormal development of this would give rise to the appearance referred to. Benedikt, who deals skillfully and acutely with the subject of fissural anomalies, seems to lose sight of this in his strong support of the relatively predominant importance here of the division of the first frontal gyrus. And I have observed several examples of more or less marked division of this frontal surface into five tiers of convolutions.

VI.—DEVIATIONS FROM TYPE PUBLISHED BY SEVERAL OBSERVERS.

Other observers have found a number of deviations occurring in brains of a low order, as, for example, those of certain kinds of criminals, those of some persons of weak intellect or insane. Of these deviations I found reason to accept some as being significant, to reject others, and to accept still others in a partial manner only; only partially accepting those inasmuch as they are valid only when in conjunction with other specific conditions, dispensed from which they cease to have the same significance; in some cases, indeed, bear an entirely different meaning. Like words in a sentence, their meaning varies with their context.

Comparing the deviations adopted from other observers with the new ones already described, the material is provided for standards or criteria of various forms of defective or

aberrant brain development. Therefore, the standard to which I shall presently advert has material derived from two factors, the one being what has been accepted from other observers, the other being what I have found for myself as anomalous; the standard is directly drawn from certain brains.

But it is in relation to one great group of mental diseases that these peculiarities of brain architecture are especially valid and enlightening. I refer to the great group of mental diseases which are essentially based in hereditary mental degeneracy, that group in which there are more or less the recognised signs of degeneracy of mind and body, in the family or collaterals, in the individual or in the stock from which he springs.

These factors of heredity and of degeneracy, of course, do not play an equally important part in all of such forms of mental disease as are subsumed here.

VII.—REFERENCE TO A STANDARD OF ABERRANT CONFORMATIONS OF GYRES AND FISSURES FRAMED AS A TEST, AND CONSTITUTING A SIGMA, OF HEREDITARY MENTAL DEGENERACY.

Throughout the above large group of mental diseases the somatic and psychic stigmata of degeneracy obtain more or less, but their form and grade differ much in the different members of it. In points of detail this subject is one of contention; but as to the broad general fact of the existence of such signs or indications of hereditary mental degeneracy, I do not entertain the slightest doubt. And I have formed a composite and sufficiently elastic standard of abnormal superficial brain architecture—that is to say, of configuration of gyres and fissures—to use as the test and criterion both of the existence and of the degree of the degenerate, defective, and aberrant developmental peculiarities found in the brain in the several forms of predominantly hereditary mental diseases.

It is not drawn from profound idiocy with its prevailing record of pathological disaster, or of gross teratological malformation; for there are weighty reasons why such a standard not seldom would be defectively applicable, and even misleading. But it is drawn from cases in which, with more or less of the somatic and psychic signs of hereditary mental degeneracy, there are innately defective and weak mental powers, with mental peculiarities or mental perversions (degrees and forms of imbecility and original paranoia and allied states).

Broadly and summarily viewed it amounts to a somatic indication, a sign-group or stigma of the insane neuropathic diathesis or of hereditary mental degeneracy. As such it is valid when applied to the other forms of mental disease constituting the large group already mentioned, inasmuch as each of them (speaking in general and in summary) is found to present a brain configuration differing from this standard one approximately about as much as the form of mental affection itself differs clinically and nosologically from the cases yielding the standard conformation of brain. And, indeed, while confirming the general accuracy of my classification, the application of this standard has solved or confirmed doubts on one or two points on which judgment had previously been held in suspense.

From other of these forms of mental defect and disease a standard might have been taken and used with various degrees of success: the one I have selected I believe to be far the best and most useful. The standard is one of mobile applicability and not of cast-iron rigidity, and affords due room for differences in detail. Not every brain of a given psychosis of the group concerned presents the same features or the same combination of them; just as, clinically, not every case of a given disease presents the same set of symptoms, or every symptom, typically present and full-blown. Precisely as with other somatic stigmata, such as the deviations from normal manifest in teeth, palate, or skull; so here the deviation is far from being always one and the same; and, moreover, certain combinations of deviations have stigmatic value.

There is not time to pursue this part of the subject further. For the present, it suffices to announce the framing of the standard. Full description of the standard and of the results of its application is reserved for future communication to the profession.

A DISCUSSION ON THE TREATMENT OF MELANCHOLIA.

Introduced by HENRY RAYNER, M.D.

Lecturer on Psychological Medicine St. Thomas's Hospital; Editor of the *Journal of Mental Science*.

THE treatment of disease is the primary object of medicine, and this objective I believe will be approached by a separate consideration of those states in which abnormal mental depression or melancholia is a common factor.

The argument may be advanced that these states do not constitute a pathological entity; that they are associated with widely differing forms of disease and of causative conditions. Melancholic states, however, have so much in common in relation to their treatment, and even in other respects, that by grouping them together from a therapeutic aspect, no risk need necessarily arise of adopting erroneous pathological views or of ignoring the varying associated phenomena.

I desire not to raise any pathological question, but I cannot avoid allusion to the intimate connection which must exist in the cortical physical substrata of abnormal mental states, even when presenting widely differentiated emotional and volitional symptoms; a view long since held by Dr. Sankey, who insisted on the pathological unity of insane states.

Clinically this is demonstrated by transitions from mania to melancholia or stupor, by sudden alternations of these states, by their occasional and partial coexistence in the same case, and in many other ways. Pathologically, owing to the recent advances in the histology of the cerebral cortex, due to Golgi, Ramon y Cajal, Bevan Lewis, Hodge, Batty Tuke, Andriessen, and others, the close relationship of these conditions has become still more obvious.

The suggestion may be made that the emotional differences and variations may possibly be due to the reaction of the organism as a whole on the local abnormal condition. This may be neural or vasomotor, or a combination of these. On so complex a subject I have no intention to enter.

Emotion has been shown by Sollier and others to be closely related to the general peripheral sensibility, especially to the visceral æsthesia or coenæsthesia; and it has been asserted by Dumas that a lowered coenæsthesia is the invariable antecedent in melancholic states, whether of somatic or mental origin, and this view is of interest in considering the mutual reactions of brain and body.

Local peripheral irritation has been frequently found to develop marked emotional changes, which have instantly ceased on the removal of the irritation. Emotions centrally originated, even in health, markedly affect all the bodily processes, and in disease these results are still more strikingly manifested.

In melancholic states this reaction of the body on the cerebral function and of the cerebral condition on the body establishes a vicious cycle of nutrition, which should never be lost sight of in their treatment.

The defect of assimilative power in melancholics is another marked characteristic. Hereditarily predisposed melancholics manifest a want of balance between assimilation and function not merely in deficiency of fat but by the slowness of their osseous development, and probably also by the smallness of their chylipoietic viscera and of their organs of circulation. The nutritional inadequacy is manifested functionally by nervous irritability and rapid exhaustion throughout life. Acquired predisposition often adds to defective assimilation defect of excretory power, manifested by a special susceptibility to all toxic conditions, and characterised by the habitually low specific gravity of the urine. Depressed emotional disorder exaggerates such defects when present, and hence in treating these conditions, whatever the associated disease, the defective assimilation and the defective elimination have also to be kept prominently in view.

Prophylaxis is the most important point of treatment. Unfortunately it is, as regards these disorders, a social rather than a medical question. Holding as I do the view that insanity should be ranked amongst the list of preventable diseases, I could wish that the State should take an active share in prevention. Legislative interference

with the marriage of neurotic persons is certainly not within the sphere of practical State medicine. The only method open to our profession, therefore, is the spreading amongst society of correct views on this and allied subjects—a very difficult matter, since harm as well as good may thus be done.

The public is fairly fully impressed with the danger of inheritance of insanity—is, indeed, inclined to over-exaggerate it, classing all degrees of heredity on a level; but it is not alive to the danger of intensifying a slight neurotic predisposition by intermarriage—for example, with phthisically predisposed persons or with those having a tendency to degenerative diseases. The danger of immature marriage in neurotic persons is also probably unknown, and is certainly disregarded amongst the lower classes, whilst the influence of rapidly-recurring gestation to the same end is ignored by the whole community.

The prophylaxis of melancholia, as far as the physician is concerned, practically begins with the management of inherently predisposed children, and his first duty is to avoid the causation of undue anxiety in regard to the family predisposition. The fear of heredity is frequently exaggerated in melancholic families, and may even become an exciting cause of the latent tendency.

The improvement of the defective assimilation powers and the avoidance of excessive centric nerve function are the two chief factors in the physical management of such children. The assimilative functions may be greatly improved by a preponderance of muscular over mental work.

The muscular development may well be aided in early childhood by systematic massage, and later by the approximately passive exercise of riding, both of which may be made to combat the tendency to constipation so often present. The essential training however should be of a monotonous unexciting kind, gymnastics, swimming, and games of skill from which competitive excitement should be excluded. The object should be the cultivation of regular habits of exercise and of the power of endurance, avoiding sudden spurts of energy or exhaustion at any time.

The development of respiratory power should be a special object of muscular training, and this can be greatly aided by the systematic practice of deep respiration. The circulatory power should also receive special attention, not only during special activity but by the use of those gymnastic exercises devised for this end by Schott and others.

Assimilation should also be aided by the sedulous cultivation of the power of developing heat. This is aided by out-of-door life, by the habitual use of light clothing except over the viscera, by the exposure of the extremities, and by the use of cold water in baths or swimming. Thoroughness of assimilation should be cultivated by regularity of meals, but especially by the intervals between these being of sufficient duration for the complete rest of the digestive cells. The food should be plentiful and digestible, rich in fats and in vegetable salts. Meat, except in the form of meat juice, etc., should not be given before the second dentition. Alcohol, tea, coffee, and tobacco should be avoided.

Mental training should be directed to the development of the powers of complete attention, memory, and observation; to completeness and thoroughness of mental function, avoiding the excitements of competition and emulation. Stimulation of the imagination should not be permitted, and the reasoning powers should be developed by suitable studies. The religious and moral training should avoid as far as possible excessive emotionalism.

Altruistic feelings should be kept well within bounds, while social habits should be cultivated as the best means of counteracting the hypersensitiveness and egoistic tendencies so often present. Timidity both moral and physical has to be guarded against and combativeness encouraged. Self-reliance often needs to be cultivated, while the love of approbation, which is apt to be in excess, requires to be checked. I believe greatly in education of the hands in definite mechanical employments in which the habit is developed of carrying a piece of work to completion. Habits of thought control should also be inculcated, and the evils of day dreaming or desultory thought should be taught. Dr. Clouston also insists on the necessity of watching over the order of development of the mental functions.

Sleep habits should receive the most careful consideration, and the hours of sleep, not the mere number of hours spent in bed, should be as prolonged as possible. Regularity is of primary importance, and attention to all details of sleep promotion. My experience inclines me to consider these children sleep best in milder atmospheres than in higher and drier air; but idiosyncrasy has to be observed even in this. Such persons should be directed to occupations which are free from sudden or periodic stress, and which are regular or unexciting. Sedentariness should be avoided. A mere lucid life is not always to be recommended. The mental power being often great, danger arises from the cravings of unsatisfied activity.

Great care should be exercised at the approach of puberty against the premature development of sexual ideas or habits of masturbation. These dangers are best guarded against, I believe, by definite instruction and warning. On this point, however, differences of opinions exist. Full occupation of time in mental and physical employment is the best safeguard. In women excess of brain work at this period is especially contraindicated.

Marriage in women should be delayed until the full development of the twenty-fifth year, for the sake both of mother and offspring; and the puerperal condition should be carefully guarded from unfavourable influences.

Melancholic states when established are remarkable for the complexity of their causation. In the same case may be found hereditary predisposition, ill habits of living, peripheral irritations, organic disorders, with toxic conditions and mental causes; and to these are sometimes added the complications of drug treatment.

In early stages the removal of one or more of these contributory conditions will advantageously affect or even completely arrest the progress of the case. Later, when the disorder has become fully established, the vicious cycle of action and reaction of the bodily conditions on the cerebral, and *vice versa*, will carry on the disorder in spite of the removal of causes which exercised a great share in its development. This view emphasises the value and importance of early treatment, especially in the pre-asylum stage, and is one in which I hope to be supported by the observations of others.

The primary step in treatment, then, is an exhaustive investigation of the patient's history, habits, and environments; a thorough examination of every bodily organ, together with the adoption of the best means for the removal or relief of any abnormality. This for the most part falls within the scope of general medicine, and requires no comment. I would specially insist, however, on the necessity of discovering and removing peripheral irritations in the early stages of disorder.

In treating the conditions directly related to melancholia those connected with functions have practically to be considered before the theoretically primary processes of nutrition. Motor activity constitutes so important a form of expenditure of energy as to need separate consideration. Within due limits it is the most potent auxiliary in the restoration of health, promoting assimilation and excretion while affording the greatest amount of diversion of mental attention with the least expenditure of cortical energy.

Muscular exertion, on the contrary, when carried to excess, may exhaust nerve centres, not easily repaired, under the existing conditions of nutrition, and which may be further embarrassed by the toxic products of waste. The old practice of walking a patient about until utterly exhausted to produce sleep was, I believe, harmful in this way. Abstinence from exercise by rest is an equally potent factor for good under certain conditions. Rest, however, does harm when wrongly used just as exercise does.

The question, therefore, that I wish you to consider is not the goodness or harmfulness of rest and exercise, but the conditions under which they are beneficial, and should be respectively employed.

Dr. Batty Tuke in a recent debate on rest and exercise advocated rest in bed as advisable in a large proportion of melancholics, and gave some very striking statistics of the result of such treatment.

The melancholic state being essentially one of nervous exhaustion and malnutrition, this mode of treatment would

commend itself as being rational; but we have to remember that although the muscles may be at rest, the mind may still be painfully active, and that therefore rest of body does not include rest of mind which these states specially need. Rest in bed and isolation as in the Weir Mitchell treatment has been found distinctly harmful in melancholic neurasthenies, but I have certainly seen such cases advantaged by rest, without isolation, accompanied by carefully arranged means of diverting the mental attention. The conditions of the rest in bed have therefore also to be considered.

My observation inclines me to the opinion that it is wisest to decide the question of rest or exercise on the merits of the individual case rather than by any fixed rule relating to the class or form of disorder. I have always used rest in bed freely, and have considered it to be necessary in cases of great physical weakness and in cases in which there was great trophic disorder where the patients emaciated rapidly. In complete insomnia, in agoraphobia, or in acutely suicidal cases I have always found it advantageous.

In all conditions, in fact, in which there appears marked depression of the innervation of the organic functions I consider rest in bed to be indicated. Sleeplessness, refusal of food, and acute suicidal impulse in my experience all subside more rapidly under this than under any other conditions. The loss of muscular activity should be met by massage, which should be made as protracted as possible so as to afford diversion of attention to the sensory impressions. The attention should also be diverted and the skin action improved by baths and hydrotherapeutic applications. Mental diversion should be furnished also by reading aloud, music, games, and every means which the mental state tastes of the patient and the circumstances admit. Supervision and companionship should be constant, and little of the day should be left without some attempts at diversion of the attention. The diet requires careful consideration; an excessive diet is commonly indicated, but in some cases even a milk diet is necessary. I have seen great harm result from excessive feeding when combined with rest.

Rest in bed with isolation is indicated in cases of extreme sensory irritability. It is specially contraindicated in erotic cases and in cases having sensory hallucinations or illusions. The return to activity must be gauged by the subsidence of the special symptoms for which it was adopted, by improvement in sleep, nutrition, and especially by improved vascular tone. In resuming activities the results of the earliest efforts must be keenly observed, and short periods of activity should be sandwiched with periods of rest. Relapses constantly occur from too great haste, and nothing taxes the judgment of the physician more than in advancing the patient to that Mecca of the melancholic—a full day in the open air.

The limitation of cerebral function, that is of cortically developed nervous energy, is the next question for consideration. The mind is more or less active in all conscious states; absolute mental rest is only possible, healthily in sleep, abnormally in stupor and similar conditions. To those engaged in the most complex mental work a change of subject, even to one equally arduous, in health may be a pleasure. A change to a less complex or more familiar subject may be an absolute rest. So that to highly developed minds engaged in complex affairs a change to mathematics or classic translation is a rest and refreshment, while still greater rest results from occupations which are more and more automatic or amusements involving mere sensory attention.

The power of persistence of function varies remarkably in individuals, so that both in quality and quantity of function we find that what is hard work for one man is idleness for another. Regulation of functional output from their point of view is therefore very difficult, and no general rule for guidance can be given.

In pure melancholic states the painfulness of all mental exertion, with other causes, tends more and more to the limitation of intellect and the consequent concentration of attention. In the extreme this is absolutely fixed in the basal most organic emotion—fear, often expressed in one idea, from which no external impression, however forcible, can for a moment divert the mind. I would suggest that the degree in which the power of attention is affected offers a good basis for guidance in our efforts to limit and direct functional expenditure.

It is also a good measure of the intensity of the disorder and a good test of progress. By the diversion of attention—where this is possible—to lower forms of mental action the functional expenditure can be definitely and systematically lessened, and this diversion probably implies comparative rest in those cerebral structures whose nutrition is specially affected.

The relation of the emotions in melancholia to their lowest form of expression must be remembered, and the painfulness of premature attempts at reviving the higher forms should be avoided. The greater the fixation of the attention the lower the scale of mental effort must we descend in our attempts to divert it. Where no voluntary attention is possible our efforts are limited to mere sensory diversion. The appeals to sensory attention may be effected in common sensation, by effluage, massage, etc., by cutaneous irradiation or Franklinisation, and by hydrotherapy, in which, by variations of warmth and force of jet, pressure and temperature sensations are added to those of touch. The hot air and vapour bath, the wet pack, and similar means act also in the same direction.

Monotonous sounds, too, were recommended by Burton, such as the sound of falling water. The diversion of attention by these means, though incomplete, is sometimes demonstrated by their producing sleep. A more powerful means of diversion is found in passive sensory impressions involving the lower forms of emotional feeling, for example, of familiarity or novelty, as in viewing new or familiar scenes, listening to music, etc. In this way even the surroundings of an asylum are often beneficial.

Volitional diversions of attention or occupation must also be employed whenever practicable, and in using these we should ascend from those that are merely motor and almost automatic to those demanding sensory attention in addition; next to those involving intellectual, sensory, and motor effort; and, lastly, to purely intellectual work. By thus arranging occupations in our minds in the order of the functional expenditure involved the estimation of their value is more easily made, as well as the extent to which they should be employed.

In order of use they should advance from the most simple and automatic to the most complex, from pulling a roller to the highest intellectual operations. In cultivating the higher forms of volitional occupation patients should be taught and encouraged to break off at the first feeling of imperfect attention, resuming after a few moments of brisk muscular exercise sufficient to stimulate the circulation: in this way the duration of attention may be gradually developed from a few minutes to hours. The greatest efforts, too, should be made in the earlier part of the day. After the last meal the attention should be diverted by the most automatic occupation or by mere sensory diversions.

The attention in melancholia is often directed to some special area of consciousness, to the entoperiphery, the epi-periphery, to the mental operations, or even to volitional side, and I would suggest that benefit is obtained by diverting attention from the affected to the comparatively unaffected activities. Thus where the attention is entoperipheral, as in the hypochondroid and hypochondriac, its diversion should be specially attempted through motor and intellectual appeals. Where the attention is concentrated on the environment appeals to the motor side are especially indicated. The hallucinated insane are amongst the most industrious of our patients, often seeming to obtain relief in the most incessant occupation.

Where introspection predominates appeals to sensory attention and motor activity are, I believe, specially indicated, such cases being specially benefited by change of scene and variety of surroundings. I believe I have found valuable guidance in the management of developing and convalescent cases from these considerations. We shall all agree, I believe, that the whole of the patient's time, as far as practicable, should be occupied by attempts at diversion of the attention, by occupation, amusement, and means of treatment. Melancholics left to their own thoughts are assuredly deepening the mill round of their disorder.

Environmental changes, with the passive influence they exert in directing attention and otherwise affecting health, demand a separate consideration.

The stereotyped statement that all melancholics should be removed from home must not be too readily accepted. Like every other means of treatment, it should only be adopted on good and sufficient reasons. Unless these are present, in the early stages, cases can often be treated to advantage at home until they are sufficiently improved to leave without suffering from the disadvantages which such a change commonly entails. Where the relations are the drawback to home treatment it is always a question whether they or the patient should leave.

These questions of change from home, travelling, asylum treatment, etc., turn on the means, the habits and experiences of the patient, the condition of bodily health, the mental state, and the prognosis—questions so complex that each decision must be arrived at on its own merits.

Those patients in whom attention can still be controlled can therefore be at times treated without removal from home surroundings (when other means of treatment are also practicable) by the revival of accustomed or even novel occupations. Usually, however, change of scene and of social surroundings is indicated both for reasons of bodily and mental health.

When attention is more engrossed by troubles, worries, etc., in the environment, change from home, family, and friends, under careful supervision becomes absolutely necessary. The effects of a simple change of locality should as a rule be tried before venturing on the complex changes of travelling or committing the patient to prolonged unalterable conditions on board ship. The danger of sending patients travelling without preliminary trial of the effect of change is very great. We must be assured that noisy hotels, irregularity of sleeping, unaccustomed or unsuitable food, and the worries of travelling, will not affect our patient unfavourably. However able the travelling companion, it is difficult to save the patient from some of these and from questions of decision of action which are often trying. Inapience and convalescence are the special stages for this remedial measure.

The social change may be limited to the companionship of a carefully selected person, medical or lay, to the society of a single household, or to the larger society of a boarding-house, hotel, hydropathic, or spa. Usually the social surroundings may be advantageously increased in this order, frequency of change of place being regulated by results. Amongst the poor little can be done in this direction, and resort to more stringent means of supervision is consequently often necessary even in this state.

When the attention is volitionally directed to the self-feeling, where there is uncontrolled expression of the predominant feeling, delusive idea, or impulse, constant supervision and control becomes necessary, either in an asylum or suitably arranged home, with a much greater monotony of environment. The form of supervision is of course mainly dependent on means, but that method is always to be preferred which brings to bear on the patient the greatest amount of individuality of skilful attention. The influence of the discipline and routine of a large asylum is undoubtedly beneficial in later conditions, but in the early stages individual attention and consideration is all important. On the care and skill brought to bear on the early stages of the condition much of the result of the case depends. Attendants and companions therefore should be chosen with very great judgment, and changed without delay if found unsuitable. As a rule the more intelligent the companion the better, but the physician has no nicer duty than the selection of the individual best fitted to deal with a given case.

Defective assimilation is always present in melancholic states—I believe it to be the fundamental defect. To inherent assimilative deficiency are commonly added bad teeth, bad mastication, bad habits of food taking, and improper or insufficient food. Such patients, from the fear of indigestion or from injudicious advice, have often limited their diet in quantity and quality until starvation has resulted. This is one of those conditions the removal of which will often produce a rest in the early stage.

Mouth disinfection is the first step in treatment. The swallowing of the salivary secretion, often retarded and even deprived of its digestive power, is a most serious matter. The next step is the relieving, if present, of any condition of

retention of food in the stomach by lavage; in hyperacidity with disinfectants and alkalies; in fermentative conditions by disinfectants followed by acids.

The quantity of food must often be, not only in excess of appetite, but in excess of actual nutritional requirements. In the young this latter limit may be largely exceeded with impunity, but later in life, with defective eliminative power, the quantity of meat food and alcohol has to be carefully regulated. Apart from the toxic reabsorption in the intestines from undigested and decomposing meat food, the assimilation of a large quantity of meat extractives may introduce an additional toxic element. Alcohol, too, useful in many forms in early life—yet always to be used sparingly—in later life must be avoided or used only for its stimulant effect at the commencement of digestion. In the later stages it impedes this function. Digestion is not only weakened in power, but slowed in process, so that provision has to be made that the food is specially assimilable, and is taken at such intervals that the stomach is not kept continually loaded.

With milk or artificially digested food, feeding may be very frequent, but with returning strength intervals of three and a-half hours or more should be aimed at. The Kneipp cure is not without its lessons in this respect. In digestibility the food must range from milk or peptonised pancreatised food, to the most *recherché* productions of the cuisine. In quality the food should be rich in fats from milk, cream, butter, and eggs. Albuminous food should be limited in elderly persons, and in this quaint old Burton's prescription may be followed. He advises "mountain birds, partridges, pheasants, quails, hens, capon, mutton, kid, and rabbit, with fish that live in gravelly waters, as pike, perch, trout, and also sea fish, solid and white, with plentiful supplies of vegetables and fruit, eaten sparingly, and not over-much of one dish."

The mode of origin of the abeyance of appetite is, I think, worthy of consideration. Does it arise, for example, from peripheral anaesthesia from lowered nutrition, from defective transmission of impressions from the periphery, from neural defect, or from toxic conditions affecting the pneumogastric centre, or from combination of these conditions?

Fear, the basal emotion in extreme melancholia, not only reduces excretion, but has been credited with producing toxic results by the arrest of metabolism. Eliminative treatment should on this view form the basis of treatment, and is I believe often effective.

The appetite is rarely in excess; toxic conditions and states of arrested digestion are probably the most frequent source of this anomaly; I should like to hear the views of the meeting on this point. The abeyance of the food appetite and the consequent avoidance or absolute refusal of food is one of the most important facts common to all states of melancholia. The basis of the objection to food must in all cases be carefully inquired into in order to exclude such causes as the unaccustomed quality of food or physical conditions of the mouth, throat, or stomach.

When the refusal is undoubtedly of psychic origin, I trust you will agree with me that we should not admit even tacitly the truth of the delusive idea by allowing patients to steal their food or to take food prepared for others, etc.; these procedures may save some trouble at the outset, but are, I believe, bad for the patient and productive of greater trouble in the end. When there is not complete control of the patient such devices may of course be temporarily adopted.

In the minor degrees of refusal much of the success in administering food turns on the skill of the administrator. Some nurses constantly fail, whilst others are almost invariably successful; the result depends, I believe, on the fact that the successful skilful feeder divides the patient's attention by appealing simultaneously to sight, hearing, and common sensation as well as to emotion by sympathetic kindness of manner or facial expression, and to the intellect by kindly talk. Such procedure with a very moderate amount of force and insistence will generally prove successful. At times a few drops poured through the nose will be effective.

Every alienist should practice feeding as he is able to instruct attendants and to prove in each case the necessity of forcible feeding. The physician should not rely merely on the statement of an attendant, but should verify the condition by observation.

With rest in bed and skilful insistence in feeding actual forcible feeding by the nasal or oesophageal tube may be often avoided. Some observers have insisted that feeding by these means need never be resorted to. In my own practice I largely avoided its use, but in reviewing the question I believe that I undoubtedly erred on the wrong side. I therefore strongly advise that it is better to err on the side of feeding too early and too often rather than in the opposite direction. Absolute refusal therefore should be met by prompt resort to forcible feeding. This is now pretty evenly divided between the nasal and oesophageal tubes. The stomach pump is now almost universally superseded by the chalice.

At a recent discussion on this subject opinions were very equally divided and each method found strenuous advocates. The advantages claimed for the oesophageal tube are the greater rapidity of administration, the power of giving a greater variety of nutriment in a less watery form, and the absence of risk of passing the tube into the larynx. On the other hand the nasal tube has the advantage in cases where there is very determined resistance.

The danger of cultivating the habit of refusal by directing the patient's attention to it is one to be strongly insisted on; the oppositeness and tendency to concentration of attention in melancholia makes this a real danger. To avoid this preparations for feeding should not be made in the patient's sight; active resistance should be overcome by such an amount of force that no struggling or delay can occur, and as little importance as possible should be given to the fact by those engaged in it. The patient's eyes should be closed during the process, which should be conducted with as little talking as possible. The frequency of feeding should be at intervals of not less than three hours and a-half, and from two to five times in the day.

It is scarcely necessary to insist on the advantage of adding lime, lemon, orange juice, or pulped green vegetables, or on the advantages of peptonising and pancreatising the food, or to direct attention to the danger of too great excess of meat extractives. Pounded meat is always preferable to beef-tea. A due proportion of the various elements of food should be aimed at. The position in which the feeding is administered and the precautions to be observed in passing the tubes are too well known to need special comment. Rectal alimentation is the last resort when feeding by the mouth becomes impracticable from exhaustion or other causes. Defermented blood has been found of special value in this respect.

The treatment of sleeplessness in melancholia is a point on which considerable divergence of opinion exists, and to which I would ask special attention. Narcotics, hypnotics, or sedatives are vaunted as important curative agents by some observers, but are utterly condemned by others. The history of these remedies is against them. Every year, almost every month, some new drug is brought out, with loud asseverations of its harmlessness, only to fall into desuetude on the appearance of a newer and more fashionable rival.

The nervous and mental disorders resulting from the protracted use of these drugs, where we have known them sufficiently long, are generally recognised, these disorders too being almost invariably accompanied by grave defect of bodily nutrition. Their most enthusiastic admirers will not claim that their beneficial action results from improvement of the general health.

The experiments of Binz, of Bonn, seem to indicate that the action of many narcotics is directly on the brain cells, not on the vessels, and this action is certainly not in the direction of improving nutrition, but corresponds rather to a pathological change.

The question may fairly be asked, In what way do these drugs affect the cerebral nutrition so as not only to avoid producing the ill effects which result from their continued use, but even to relieve abnormal conditions often of long standing? The inquiry may also be made whether the state of insensibility produced by them is identical with normal sleep. In the latter nutritive repair and active reabsorption take place. Do the same changes occur in insensibility from drugs? The experiments of Hodge make it possible to hope that this question will soon be answered on the physical side, and the investigations of Kraepelin in regard to their

effects on mental reactions will probably give a solution from the mental aspect. In the meantime we must be content to rest on observation and experience. The phenomena involved are so complex and little understood that the briefest presentation of them would occupy all the time at my disposal. I would ask, therefore, for expressions of experience and observation rather than for discussion of theory of action. In the past many eminent men have expressed opinions in favour of the curative influence of these drugs. The balance of opinion, however, has I think steadily shifted, and of those who still believe the belief is limited to some one drug or to some special limited form of disorder. The opinion, not of inutility merely, but of their harmfulness and deleterious effects is, I believe, also growing.

My personal observation has led me to the conviction that narcotics and sedatives are often pernicious in melancholia: that they almost invariably protract and intensify the disorder, and their systematic use is to be avoided by every means in our power. Only under conditions in the environment of the patient which preclude other means of treatment do I consider them even temporarily admissible. They are dangerous, not only by exaggerating the condition, but by leading the physician to neglect the more legitimate means of combating sleeplessness and disorder. They are dangerous also to the public, who too readily obtain them under cover of the physician's prescription in their belief of the harmlessness which attaches to the latest novelty.

My opinion is based on results in cases treated by myself, in the great improvement following on omitting their use even where other conditions remain unchanged, on the expressions of those who have been subjected to their influence and on the symptoms of mental confusion and stupor sometimes introduced into otherwise simple cases.

Sleeplessness due to peripheral irritation, as, for instance, in the presence of undigested food in the stomach, must be met by removal or avoidance of these conditions. On this I need not dwell.

The sleeplessness of melancholia is probably due in most cases to the arterial supply not being sufficiently inhibited to reduce it to the level which obtains in normal sleep. Occasionally, however, the sleeplessness appears to be due to excessive inhibition or anemia. In the majority of cases, therefore, the object must be to divert blood from the cerebral area to other areas of the body, especially, of course, to the abdominal; or where this is for any reason undesirable, to the limb areas. Primarily we should remember that the condition of defective vasomotor inhibition is probably due to the cry of the ill-nourished cerebral cells for nutriment. The first sleep in insomnia usually follows on the taking of food: in slight degrees this occurs directly on the ingestion of nutriment by the mere diversion of blood, but in more severe cases sleep follows later when it is probably due in part to the added supply of nutriment. The return of sleep at the accustomed hour should be promoted by making this correspond with the completion of the digestion of the last meal; this should not give any cause of peripheral irritation, but should be as nutritious and digestible as possible. The brain should also have rest by the avoidance of intellectual effort or emotional excitement during the latter hours of the day.

The diversion of the blood to the abdominal area may be affected by hot fluid food, hot fluids, or a small amount of stomacheic stimulation. The general diversion may be accomplished by stimulation of the cutaneous surface by warm baths, the warm pack, abdominal compresses, etc. Stimulating applications of mustard in various ways may also be used. Cold to the feet followed by brisk rubbings is at times efficacious.

No trifle in the environment is too minute to be taken into consideration in the struggle for sleep. The temperature of the air, clothing, exclusion of light and sound, and many minutiae must receive thoughtful attention. In toxic conditions free action of the skin by the warm pack, etc., is specially successful. Where anemia is suspected, stimulation of the circulation by a hot bath of short duration or by stimulants is sometimes successful. I have found ergot succeed in some cases of this kind. Digitalis has been advocated by Dr. Batty Tuke in the ordinary conditions. Absolute rest in bed is indicated in extreme cases, but the

best narcotic in our pharmacopoeia is a day spent in the open air with exercise short of actual fatigue.

Sleeplessness dependent on associated conditions of disease must be met by appropriate treatment. The suicidal tendency common to most melancholic states has to be met by the familiar methods of removing means and avoiding opportunities. The danger of directing the patient's attention and exciting opposition is here also to be feared. *Ars est celare artem*: the patient should be as little conscious as possible that supervision is being exercised, and this, as far as practicable, should be ascribed to other reasons. Rest in bed, or in restless cases in a padded room, is necessary in the most acute stage, but life in the open air is the condition to be aimed at. The actual manual control by an attendant or attendants is always to be avoided; the constraint of a padded room under continuous observation or the freedom of a meadow are always preferable. The relaxation of supervision is a question which must be decided on the merits of each case.

In the moral treatment of melancholia the first step is to gain the confidence of the patient. The most careful and exhaustive inquiry into the feelings and ideas of the sufferer is absolutely necessary. Until we have discovered the fundamental melancholic idea complete confidence is not gained, and the physician's personal influence for good is greatly weakened. In the earlier stages of disorder I consider this influence of the utmost importance. With the complete confidence of the patient reason and volition may often be actively enlisted, and the suggestions of the physician under these conditions have a great influence on the progress of the case. Hypnotic suggestion can rarely be employed in melancholia, and I consider that it should be avoided, since by it volition is weakened rather than strengthened. The confidence of the patient must be retained by absolute truthfulness, by sympathy and firmness. Persistent hopefulness, too, is not without its effect on these patients, however strongly they may deny its influence.

Arrest or recovery in melancholia sometimes follows physical or mental shock, or the excitations of strong emotions. Thus sympathy for friends in sickness and trouble, or the pressure of a real anxiety, will sometimes result in cure. Emotional influences can rarely be brought into play therapeutically. Religious emotion has been tried, but in my experience it is a dangerous means of treatment. Fear also is a double-edged instrument, although at times successful.

Against established delusions all direct reasoning is hopeless, harmful, and to be avoided; those founded on illusion and hallucination may however be excepted. In the stage of doubt, whether in the inception or retrocession of delusion, reasoning and kindly ridicule, especially when indirect, are not without their effect. Fears and obsessions in the early stages may be combated by systematic volitional efforts made at the suggestion of the physician.

Treatment aiming at directly affecting cerebral nutrition is of great importance. Massage of the head, specially with a view of emptying the veins of the head, is of great service; the downstroke of the hands over the head and neck should be accompanied by deep respiration, which more thoroughly empties the veins and probably also the lymphatics. The patients readily learn to do this and should, where possible, practise it frequently during the day. The practice of deep respiration alone, I am assured by a competent observer, has been found of marked benefit in some cases.

Hydrotherapy is of great service. The most beneficial results are, I believe, obtained from alternations of heat and cold by showers, douches, or even cans of water over the head. The alternations should be as extreme as can be borne, to obtain the most marked effect. In women with whom the wetting of the hair is a difficulty, a stream or jet of water directed over the cervical sympathetic may be used. In the young, cold shower baths are of the greatest use; in less robust persons, cold showers to the head may be given with a warm bath. This is of a special use also in some toxic conditions.

Electrotherapy offers, I believe, much scope for aiding the restoration of local nutritional disorder. Especially should this result from galvanism of the sympathetic since the cerebral circulation can be most markedly affected by this

means. With a positive pole in the auriculo-maxillary fossa and the negative on the chest, determination of blood to the head is effected; with the poles reversed, pallor, feeling of emptiness of the head, and vertigo result.

The alternations of these actions, by increasing the cerebral vasomotor activity, might favourably influence nutrition. At present however no conclusive results of treatment are on record.

Galvanism of the brain is of much more difficult application and of much less definite results. It has been specially recommended in conditions of restlessness and excitement.

Faradisation and Franklinisation are chiefly of use, I believe, in directing sensory attention to the cutaneous surface. They should be prolonged in use and varied in locality. Benedikt, Arndt, and others credit peripheral Faradisation with a reflex action on the nervous centres. Counter-irritation is much out of fashion, but I have often found it of advantage in cases verging on stupor, when uncomplicated with toxic conditions. The counter-irritation should not as a rule cover more than the area of a florin, and should be repeated every few days in a fresh locality. Derivation by setons, etc., I have rarely tried, but it is quite possible that they might be found useful adjuncts to treatment in toxic conditions.

Intercurrent febrile conditions have often been observed to restore mental health in the more stationary conditions of melancholia, and in the thyroid extract we appear to have a means of inducing artificially a controllable febrile condition which may imitate these results. The effects of this treatment in the hands of Dr. Clouston appear to have been very striking, but time and further observations are needed to formulate conclusions, both as to results and mode of action.

General treatment must be directed to the promotion of elimination by the skin, kidneys, and bowels. On the best means of effecting these objects I need not dwell. I would, however, insist on the vast importance of making all melancholics ingest large quantities of water or watery fluids, not necessarily with meals, when they often cannot be digested. The habitual use of the hot air and vapour baths is also an important means of treatment especially indicated when there is a toxic condition or suspicion of defective elimination. The warm pack, too, is very beneficial under similar conditions.

Medicinal treatment in uncomplicated cases should be tonic from the outset. Stomachic vegetable bitters and stimulants, such as cardamum and capsicum, are useful. *Nuxvomica*, cascara, and other intestinal tonics are indicated to aid in overcoming constipation. Constipation must be relieved by the usual dietetic and regiminal means, avoiding the use of purges. Iron, where it can be borne, is usually required, administered in small doses largely diluted in effervescent water. Various spas may be visited for this, but the most important point for the assimilation of iron is the taking it largely diluted before food on first rising. Preparations of phosphorus are also useful, but from most of the so called nervine stimulants I have obtained little advantage.

Increase of weight is usually a safe guide in progress in the treatment of melancholia, and in the prophylaxis of relapse stringent watch should be kept on any decrease in this respect or any return of sleeplessness. In other respects the rules for prevention may be applied in the prophylaxis of relapse.

This brief and imperfect summary has necessarily involved allusion to many facts which are so familiar as not to have needed any repetition to such an audience. I trust, however, I have touched on some points which may lead to interesting and useful discussion, and I beg to thank you for the patient attention you have accorded me.

The President thought that the overfeeding of melancholics was too universal, and that in some cases of melancholia the stuffing method of feeding was not good treatment, the object required being to get introduced just as much for nutrition as can be assimilated, as, for example, in cases with renal disease and cardio-vascular degeneration.

Dr. FIELDING BLANDFORD said it was impossible to go

through the treatment of melancholia in ten minutes, but he wished to touch on one or two points chiefly concerning patients in the early stage. The question arises, Shall the patient be treated at home or away? If away, where shall he go? He was of opinion that to recommend a sea voyage was bad advice; it was monotonous, there is always the danger of suicide, and there is little to distract the thoughts. Change of scene with appropriate companions was useful, and the majority had to go, but here and there we find a man, whose business is unexciting, who benefits by remaining at his regular occupation. He thought great improvement followed the use of hypnotics in the early stages where six or seven hours' sleep might be substituted for two or three.

Professor VON BENEDIKT (Vienna) touched on the etiology of some special forms of melancholia. The first, he said, was what we might name the "female conjugal melancholia" which is caused by the absence of *libido sexualis* in time of conception, gravidity, and birth. One must guess the reason, as patients will not speak of it, and are not conscious of the reason of their state. The second form he called the "melancholia of the fiancée," which arises from the fear of not being a pure virgin. This usually occurs in the most innocent girls. He then went on to say a few words about electrotherapy in melancholia. He considered Faradisation and the Franklin douche most useful in producing sleep where patients are not degenerated by the use of narcotics. He thought that by the continued use of narcotics cases were often aggravated and prolonged, but their occasional use was sometimes beneficial. In cataleptics, he said, the application of galvanic currents with voltaic alternatives along the spine often had the desired effect. He often gets good results from the use of cocaine (3 or 4 milligrammes daily) in melancholia.

Dr. LIONEL WEATHERLY (Bath) thought that Dr. Rayner's paper had been so exhaustive that but little remained for one to say, but there were a few points of practical value which could not be too strongly or too often accentuated. First, he thought the question of gaining the confidence of your patient a most important one, and also that of getting our attendants to do the same; moreover, we should insist that the attendants never attempt to get the patient to obey their wishes by false promises or any process of deception. With regard to rest and exercise, his old friend, Dr. Milner Fothergill, used to insist that there was a fatigue point varying in each individual and at different times, and that beyond this point, whether in rest or exercise, we must not go. He did not think Dr. Rayner made quite enough reference to those cases of melancholia caused by some peripheral irritation, such as hemorrhoids, papillomatous growths of the rectum, etc. It was most important that these causes should be discovered as early as possible, and by early treatment hopeless hypochondriacal melancholia be prevented.

Dr. NORMAN KERR (London) called attention to the considerable part played by alcohol in the etiology of melancholia as probably due to alcoholic disturbance and perversion of the digestive process. He had often found that restoration of the digestive function had removed the disease. He quoted a case, however, of an abstainer, aged 85, who was cured for a time, after all other remedies had failed, within a fortnight. Dr. Kerr had often found the hot and cold pack useful in procuring sleep, and amongst drugs phenacetin, without any injurious effects. He thought a long sea voyage risky, but a tour with sea and land alternating he had frequently seen most beneficial.

Dr. CLOUVERON (Edinburgh) asked what is the immediate cause of the painful consciousness that is the essence of the melancholic? To obtain this we have to ask its physiological correlation—namely, What is the source of pleasure? He replied unhesitatingly the performance of function is the great source of pleasure; and, in the typical melancholic, the performance of function causes pain, not pleasure. The mechanism through which pleasure arises must, he said, be referred to the sensory cells and the mental sensory cells in the cortex. He believed that in melancholia it was the katabolic process of this cell that had gone wrong, and that it had become too sensitive and too affectively explosive. Were that cell in a normal static condition, no mental pain would result from the toxic poisonings or the reflex irritations that

stand as causes of melancholia. He believed most strongly that the vessels and lymphatics, the neuroglia and the membranes, were the servants, and not the masters, of the cortical cell. He quoted the case of a man who had periodic attacks of sane melancholy, which was always cured by $\frac{1}{2}$ grain of morphine. He thought this sudden cure due to the morphine increasing the static, and diminishing the hypersensitive and explosive condition of the cell. As hypnotics he believes morphine the least applicable, and mentioned paraldehyde, sulphonal, antipyrin, and chloralamid as being of immense value. He believed exercise to be more beneficial than rest, but that both measures were applicable at different stages and in different cases. He thought that by far the best thing we could do was to fatten the patient by every means in our power.

Dr. BATTY TUBE (Edinburgh) agreed with Dr. Clouston that the vessels were the servants of the brain, but thought that the latter might go wrong, and that the morbid state of the nerve cell was not necessarily primary but might be secondary to a disordered vascular system. He had long laid down that it was not work but worry that was the more important factor in the production of melancholia. He believed in the efficacy of rest in bed in the treatment of this disease.

Dr. NICOLSON (Broadmoor) also thought that the circulation should not absolutely be left out of the question of causation. Indeed, Dr. Clouston's case of the gentleman whose melancholia was repeatedly cured by one hypodermic injection of $\frac{1}{2}$ grain of morphine, it appeared to Dr. Nicolson either the case was not one of melancholia, or else the cell structure could not have been very seriously deranged. Dr. Nicolson's experience as to melancholias whose melancholia came to a climax in the commission of a homicidal act, pointed to a number of cases where the act being of the nature of an explosion the mind settled down with remarkable quickness, and the patients described it as being like a cloud passing away. In some, however, this is not the case, and lasts longer. As to the treatment of melancholias at Broadmoor, the greatest and most potent curative influence was that exerted by convalescent and improving patients, who were at great pains to help the new arrivals in the hospital in every way in their power.

Dr. ELIZA WALKER DUNBAR (Bristol) remarked that the early stages of melancholia came before the family doctor, who meets with many special difficulties in treatment. First, the public are ignorant of nerve physiology, and cannot understand that nerve tissue requires rest, time, and favourable conditions to recover; and, secondly, the patients themselves, who do not rightly appreciate the causes of their depression, and fail sometimes to mention them. As regards prophylaxis she thought the appointment of doctors to watch over the pupils at schools might have some good effect.

In reply, Dr. RAYNER agreed with Dr. Blandford in reference to the sea voyage, and with Dr. Weatherly, in that the attendants should aim at gaining the confidence of their patients. Hypnotics, when continually used he believed harmful, and agreed that the removal of peripheral irritation was most important. In reply to Dr. Clouston he thought the nerve cell rather defied, and that we must take into consideration the blood and lymph supply.

MENTAL SYMPTOMS IN RELATION TO EXOPHTHALMIC GOITRE.

By A. MAUDE, L.R.C.P.

MR. A. MAUDE read a paper on this subject in which he contended that there was a very definite form of mental change, only lacking in one of his 20 cases, characterised by extreme motor restlessness, extreme insomnia, and occasional sensorial illusions of sight or hearing, but it is doubtful whether some cases of auditory illusions are not dependent on Eustachian catarrh, which Mr. Maude has found common in Graves's disease. He found that the more peculiarly psychical changes were irritability, incapacity for mental application, loss of memory, and untruthfulness, and Sir J. Russell Reynolds has described a condition quite common as "chorea of idea." Another common condition is a morbid sense of duty akin to

religious melancholia, but not accompanied by definite melancholia. If definite alienation, which occurred in only one case of the author's 20, does take place, the commonest form is melancholia; delusions of persecution are also frequently seen. Mania occurring in the course of exophthalmic goitre is of bad augury.

MENTAL SYMPTOMS OCCURRING IN BODILY DISEASES.

By ERNEST SEPTIMUS REYNOLDS, M.D. Lond., M.R.C.P.,
Senior Physician to the Ancoats Hospital, Manchester; Physician to the
Manchester Workhouse Infirmary and Lunatic Ward.

It would be impossible in a single paper to adequately treat of the mental symptoms occurring in bodily diseases, so this communication will only include the results of personal experience during four years' residence in the Manchester Royal Infirmary and five years' work as visiting physician to the Manchester Workhouse Infirmary, which contains over 600 medical beds.

Mental symptoms occurring in bodily diseases may be at the outset divided into those slight mental changes in the feelings and emotions not amounting to actual certifiable insanity, and secondly actual insanity occurring in bodily diseases.

The slight mental states may be roughly subdivided into pleasurable feelings, depressed feelings, conditions of mental dulness, abnormal irritability of temper, and feelings of terror.

Pleasurable feelings, as might be expected, are uncommon, but are seen in some cases of phthisis (spes phthisical), in the early stages of certain poisons (alcohol, chloroform, cannabis indica, and opium), and occasionally in the dying, especially where there is a deep religious feeling.

Mental depression is by far the commonest slight emotional state met with, and may be a natural feeling caused by pain or actual personal inconvenience, or it may be an entirely unnatural depression quite incommensurate with surrounding circumstances. It is found proverbially in abdominal diseases, excepting, curiously enough, in splenic disorders; for the old expression "fits of the spleen" for lowness of spirits and irritability of temper does not seem to be borne out by clinical observation. Contrary to the usual statements, mental depression and more or less hypochondriasis are very common in phthisis, especially as it is observed in the wards of a workhouse infirmary. Intense depression accompanies, and sometimes follows, various fevers, such as rheumatism and influenza. In the interparoxysmal periods of epilepsy depression and hypochondriasis are often marked features, and the after-effects of poisons, such as cannabis indica, opium, alcohol, and carbon bisulphide, are those of depression. Alcoholic paralysis is accompanied by great depression, especially in women, more often by exaltation in men. Vague dragging abdominal pains and hypochondriasis in women should always lead one to examine for movable kidney. The presence of hair on the face in women causes great depression, which may lead on to true melancholia and even suicide.

Mental dulness (which must, of course, be distinguished from unconsciousness) is found in cerebral tumour, in intense headache, in phthisis, in cyanotic states, in disorders of the liver such as cirrhosis and cancer, in cancer of the stomach, and especially in myxœdema.

Irritability of temper, common enough in sick children, is especially common in two diseases of adults, namely, phthisis and diabetes; it is also seen in the gouty, in various forms of dyspepsia, and may accompany painful conditions such as toothache or sciatica. Feelings of terror occur in hydrophobia, delirium tremens, and possibly in chorea and Graves's disease.

Actual insanity occurring in bodily diseases should not include the insanities connected with mental bodily changes such as those of puberty, childbirth, and the climacteric and senile periods. Insanity may occur in any of the following classes of disease: (1) Organic disease of the nervous system, whether cerebral or spinal (including Graves's disease); (2) disease of the heart; (3) disease of the lungs (excluding phthisis); (4) disease of the digestive organs; (5) disease of the urinary and generative organs; (6) certain general

diseases, such as gout, diabetes, and myxœdema; (7) diseases caused by æcma, including tuberculosis and rheumatic fever; (8) vegetable and mineral poisons; (9) traumata, including surgical operations. A few remarks only will be made on some of these subdivisions.

Insanity may be found in cerebral hemorrhage or softening, and may take the form of acute mania, with incoherent and noisy raving and dirty habits; there may be melancholia or mere simple-mindedness, lapsing into complete dementia; some of the early acute maniacal cases recover after a few days or weeks. In the majority of chronic hemiplegies the mental symptoms may only consist of slight emotional changes, slowness of comprehension and judgment, and slight loss of memory; but beyond this there is often but slight mental change. An examination of the testamentary capacity of about eighty hemiplegics showed that those with left-sided hemiplegia were almost all capable of making a will, and it was only amongst those with right-sided hemiplegia that I found any large proportion who were not mentally fit to do so; a result which might have been imagined *a priori* from the presence of the speech centres in the left hemispheres. I have on several occasions known patients suffering from sensory aphasia (word blindness or word deafness) sent to asylums as insane, because of their apparently irrelevant answers to questions, or because of their loss of memory of names, but a careful distinction must be drawn between this condition and actual insanity, and, as a rule, these patients are not proper subjects to be detained in asylums.

In cerebral tumours mental symptoms as a rule come on late, and may be those of steadily progressing dementia, of melancholia, or of hallucinations, with maniacal excitement.

Insanity associated with Graves's disease is in my experience very rare. I have only seen one case in an asylum (acute mania), and another case with mental depression with slight delusions of suspicion. Insanity secondary to organic spinal disease is not common. It may occur as a melancholia or a dementia in disseminated sclerosis (but only when the brain is also affected) and also in locomotor ataxia which very rarely passes on to general paralysis of the insane. I have at present under my care two cases of pure locomotor ataxia who have had delusions of persecution and hallucinations of hearing, the mental disturbance having, however, recovered in about three months.

Occasionally one meets with insanity in valvular disease of the heart. It is sometimes impulsive in nature, as in two acute cases who both suddenly committed suicide by jumping from heights. More frequently it takes the form of delusions of suspicion and persecution, and a similar condition may be seen in lung affections associated with dyspnoea and cyanosis, the symptoms generally beginning or being chiefly present at night. Very rarely ideas of grandeur are seen in heart disease, but from numerous cases seen in the last twelve years I have been unable to differentiate various forms of insanity as peculiar to various forms of heart disease.

In the terminal stage of gouty kidney, there may appear a wild delirium, or more commonly a noisy acute mania with possibly homicidal impulses and delusions of persecution and poisoning, the immediate friends being often the subjects of attack.

Amongst the diseases caused by germs we find a comparatively large amount of mental disease. Very rarely pneumonia is accompanied by true acute delirious mania (to be distinguished from delirium tremens, so commonly seen in the pneumonias of alcoholics). After pneumonia and typhoid fever a stuporose demented condition, or a melancholia with delusions of suspicion and poisoning, may occur, these cases almost invariably recovering in a few days or weeks. Influenza may set in with very acute mania, with great excitement, delusions, and hallucinations, recovery occurring as a rule; or there may be suicidal attempts in the early stage; after influenza melancholia may set in; less frequently, mania.

The question of so-called phthisical insanity, as judged from the general hospital and not from the asylum point of view, leads me to the opinion that a very small proportion of the phthisical become actually insane; certainly not more than $\frac{1}{2}$ to 1 per cent. The mental symptoms generally pre-

sent themselves as delusions of suspicion and poisoning occasionally with suicidal attempts, but the type of insanity has appeared to me to be in no wise different (except in the prognosis) from the insanity occurring after pneumonia or typhoid fever. My experience, then, does not lead me to believe that there is a type of insanity peculiar to phthisis, or that phthisis predisposes to insanity in any more marked degree than the other fevers.

I have never seen actual insanity in acute rheumatic fever, but quite recently had a case of gonorrhœal rheumatism who developed very acute mania which recovered within a month.

The ordinary insanities due to alcohol are well known, but in alcoholic paralysis there is very often a peculiar loss of memory of time, and the whole of the mental symptoms seem often to depend on this one factor. In other cases of alcoholic paralysis we occasionally see a peculiar delusion, that the patient has a child abed; and this idea is found, not only in women, but sometimes in men.

Within the past few years a process has been used in making macintosh garments for taking away the adhesiveness of india-rubber, and in this process large quantities of carbon bisulphide vapour were inhaled by the workers. (The work-rooms are now much better ventilated than they were formerly.) Under the influence of the gas the workmen became very talkative and incoherent, they had vivid hallucinations, became very excited, and performed curious antics, such as turning somersaults, etc. After a few minutes in the open air the mental symptoms gradually passed off. In several cases, however, the mania was lasting and the patients had to be sent to an asylum as they were quite insane, sometimes permanently so.

Although many cases of lead poisoning are seen in a large industrial population, I can only recall three cases of insanity associated with it—one case of acute mania with delusions of suspicion, and two others with symptoms very like those of general paralysis of the insane (tremors, slurring speech, and partial dementia), but with depression instead of exaltation.

As regards mental symptoms following closely after injuries or operations, I should like to corroborate the opinion of Mr. Clinton Dent that true delirium tremens is more often diagnosed than seen. In the majority of such cases which I have seen in surgical wards the mental condition present was one of acute mania, often very noisy in character and associated with very vivid hallucinations of hearing and sight. Usually the excitement is of a pleasant character, sometimes, however, being accompanied by depression.

As a summary of these very discursive remarks, my own experience leads me to conclude as follows: 1. It is a comparatively rare occurrence for actual insanity to develop during the course of bodily disease. 2. In general hospitals mental disease most commonly occurs after fevers, poisons, injuries and operations, and heart disease (in about this order of frequency). 3. In the early stages of fevers and after injuries and operations mania is the common form of insanity, but in other conditions depression is more common; but the commonest form is an insanity with marked delusions of persecution (often associated with hallucinations of hearing), such as one sees in phthisis and heart disease and after typhoid fever. 4. There is no special form of insanity connected with special bodily disease, so that it is impossible to diagnose the bodily disease from the mental symptoms present (except the peculiar mental state of alcoholic paralysis). 5. Insanity occurs with unusual frequency in bodily diseases associated with peripheral neuritis, as in poisoning by alcohol, carbon bisulphide, and lead; pellagra, typhoid, typhus, scarlet, and rheumatic fevers, influenza, pneumonia, phthisis, syphilis, septicæmia, rheumatism, gout, and diabetes. Is it possible that in these conditions the factor which causes the changes in the peripheral nerves causes also some similar changes in the multitudinous internuncial fibres in the brain, and so produces disturbances in the normal cerebral reactions which go to make up a healthy mind? 6. Where the cause is not continuous—such as the poisons, the fevers, and the traumata—the mental symptoms in the great majority of cases disappear; in heart disease and phthisis they may disappear and reappear from time to time; but in some cases, such as the insanity connected with gouty kidney, they only disappear with death.

Dr. URQUHART said it was a treat to hear the work done by others not so intimately connected with mental work, and it was fortunate to have men struggling with the lesser forms of mental disease. He briefly alluded to a few points in Dr. Reynolds's paper.

The PRESIDENT thought that mental symptoms were often associated with spinal disease.

Dr. CLOUSTON quoted some figures proving that there most certainly was a phthisical insanity.

SOME MENTAL STATES ASSOCIATED WITH VISCERAL DISEASE IN THE SANE.

By HENRY HEAD, M.A., M.D.

POWELL These mental changes which accompany disturbances may be classified under two groups, as follows: (a) Those changes which accompany the disease directly, and are associated with the presence of some abnormal product or tissue change produced directly by the disease (for example, myxodema). These may be called the direct mental effects of visceral disease, and will be neglected in this communication. (b) Certain mental changes which are only present in those cases where the visceral disturbance causes what is known as referred pain associated with tenderness of the superficial structure of the body and scalp. Now this pain and tenderness are due to changes in some part of the central sympathetic system caused by disturbance of the internal organ to which sensory sympathetic nerves are supplied. Thus the mental changes of this group may be said to be indirect, for they are associated with visceral disturbances through the mediation of the sympathetic system.

II. In this communication only the sensory and emotional changes of this group are considered, and the marked changes which may be present in attention and memory are reserved for the fuller communications in a future number of *Brain*.

1. The first change to which I wish to draw attention is a melancholia coming on with extreme rapidity, and lasting a variable time (from a few minutes to several hours). These attacks are completely causeless and may occur with such suddenness as to interrupt a conversation. Under such circumstances the patient leaves the circle with all the appearance of a person leaving the room to vomit. He sits in some room apart weeping uncontrollably, without any idea of the cause of his sorrow. He may be sitting quietly and controlling himself with difficulty when a kind word from a passer-by will set him crying with even greater ease than a sharp speech. Music is intensely disagreeable, and such people will shun any ward or place where singing or playing is going on. During these attacks the patient has an intense feeling that something ill is going to happen, but is unable to say definitely to whom or what the nature of the ill may be. It is a vague but intense feeling of impending ill which makes him write home to know if anything has happened, or leave the hospital and go home. In one case a man with phthisis was so certain something was going to happen that he wrote his name and address on a card and pinned it into his coat before leaving the workshop. All patients in this condition sit apart in some unfrequented part of the wards, and if spoken to give a short answer and then get up and go away. At the time of the attack it is exceedingly difficult to get any information from them, and one is forced to wait till the attack has passed off or is lessening to obtain an account of their feelings. Those patients who can visualise strongly are haunted throughout their attacks by a constantly recurring picture of their home, "dark and miserable, as if in a fog." All colours have disappeared from the room and become grey or black. There is no fire in the grate, no lamp on the table, no sunshine coming in at the window; everything is dark, dull, and dreary. But not only are the colours absent, but everything in the picture of home appears out of place; the tables and chairs are in disorder or upside down. One man described it as "just as if the brokers had been in." This condition of mind may be accompanied by a distinct impulse to suicide, but the impulse is diffuse and not specialised. The reason apparently that it is so seldom acted on is the rapidity with which the emotional disturbance disappears, and the curious fact that the locomotion

necessary to carry out the impulse to self-destruction tends to abolish the desire for suicide.

Compare with this what may be called causal melancholia as it occurs in the sane, especially in certain cases of phthisis. The patient perhaps begins the day not feeling quite well, and he begins to think of his wife and family and the possibility he may not work again. His cough is a little worse and he thinks he is losing weight. He becomes increasingly miserable until someone rouses him to take part in conversation or some game, or perhaps he visits a theatre or concert hall. He then loses his misery. This is a totally different condition from the paroxysmal causeless melancholia described above, with its sudden onset, feeling of indefinite impending ill, distaste for the society of friends, hatred of music, and causeless weeping.

2. *Hallucinations*.—These may be of sight, hearing, or smell. Probably hallucinations of taste occur, but the month is usually in such a condition that it is impossible to be certain that the taste experienced has not an objective basis. All the hallucinations are of a low type. Those of vision consist of a figure or head, either black or white, but never markedly coloured. The figure is draped and not clothed. Intelligent patients of the lower classes have difficulty in explaining this difference, and more than one has volunteered the statement, "They are draped like statues, not dressed in proper clothes." The faces are black, white, or frequently the head is draped "in a sheet," as the women patients usually say. The figures occasionally have long dark hair, and yet the patient is always in doubt about the sex. Sometimes the figure appears at a distance and approaches; at others it flits across the room and out by the opposite wall. In no case are the limbs evident, except only in those rare cases where the hallucination takes the form of a hand appearing through some opening. The figure never speaks, but occasionally seems to grimace.

Of 16 hallucinations of vision in sane patients suffering from visceral disease, 13 were figures wrapped in a sheet or draped. (Of these, 9 were "dark" or "black," 4 "light" or "white." In 7 the face was expressly stated to be "covered." One was said to have a black face, and 1 a very pale face.) Two hallucinations consisted of a face at the bottom of the bed. One took the form of a black hand coming round the half-opened door.

Hallucinations of hearing are not articulate voices. Rarely they take the form of inarticulate voices speaking together or singing "all together and out of tune," but no words are heard, and these patients never think they are spoken to, as is usual amongst the insane. Sometimes the hallucination takes the form of a bell or bells, which grow fainter, and then return, to again grow fainter. Sometimes a noise of knocking is distinctly heard, and the patient will get up three or four times to open the door, so certain is he of the knock in spite of the protests of bystanders. One man sent his wife down in the middle of the night to see why they were mending the road. Taps are heard on the outside of top storey windows. Of 17 hallucinations of hearing, 7 took the form of a bell or bells, 7 knocking or tapping, 2 the sound of a whistle, and 1 of loud breathing under the bed.

Hallucinations of smell are much more difficult to investigate, but seem to occur with considerable frequency. They are uniformly offensive drains, rotten fish, "deathly smells," burning rags or oil, escape of gas are some of the forms assumed by these hallucinations. Now, it is obvious that these are all closely akin to objective smells which may occur in a hospital, and I have therefore exercised a most rigid censorship in all cases of supposed hallucinations of smell. No hallucination has been counted unless the possibility of an external cause could be excluded, and unless the nose had been examined at the time. These hallucinations differ from smells depending on an objective cause in that they are almost always associated with nausea, and occasionally followed by vomiting. A patient may be in the middle of a meal when the hallucination occurs, and the meal is then at an end, and he is obliged to leave the table. I have seen a patient put the remainder of the supposed stinking food aside, certain from previous experience that she would be able to eat it when the smell passed off.

3. The next mental change to which I wish to call attention is a form of delusion of suspicion.¹ These patients fancy that their friends are against them, and when they see

¹ Physical exaltation also occurs, but I must leave the consideration of this form of delusion to the complete paper, as it is too complicated to treat in a short communication.

two people talking together they imagine that these people are talking about them. They always deny that they actually hear what is said, but they are certain all the same that they are being talked about. Just as we found that the hallucinations were of a low type, so here the delusion is broad and ill formed. They believe their friends "want to get rid of them," that "their fellow workmen want to get them sent away," that the master or mistress or superior officer think them "lazy and idle." If they think people are talking about them, it is always that they are lazy, idle, good for nothing, ought to be got rid of. Under no circumstances do they ever imagine a definite charge of fraud, impiety, or immorality, but only of laziness, idleness, physical incompetence. So vivid is this delusion, that these patients frequently accuse their friends, fellow workmen, or employers of desiring to get rid of them; but though impelled to make the charge, they have a sort of feeling that it is not true, and are ready to accept a simple denial.

4. The changes in attention, memory, and temper which occur in these patients will be treated in the full paper, as the conditions under which they occur are much more complicated than those necessary for the production of the changes mentioned above.

III. These changes are associated with the presence of referred pain.

Disturbance of the various organs of the thorax and abdomen may cause pain which is what is called referred as opposed to local. This pain, if sufficiently intense and of sufficient duration, will be accompanied by tenderness of the superficial structures of the body.* Whenever any of the areas on the neck, chest, or upper abdomen are present (third cervical to subumbilical inclusive), they tend, if sufficiently intense, to be accompanied by tenderness of the scalp, as I showed in my second paper†. In most cases the presence of body tenderness without scalp tenderness shows that the disturbance is not very profound, and thus the presence of scalp tenderness, with any disturbance of the thoracic or abdominal viscera, assures us that the disturbance in the nervous system is well marked.

1. On classifying 169 cases of visceral disease of which I have complete and careful notes, we find that 87 cases suffered at one time or another from referred pain associated with superficial tenderness. Of these 87 cases 60 showed the typical depression I have described above, 31 had hallucinations during their stay in the hospital, 19 gave a history of hallucinations before admission, and 32 showed the delusion of suspicion. Of the 82 cases without referred pain or tenderness, none showed the depression, and none had hallucinations during their stay in hospital; 3 gave a history of hallucinations before admission; none showed the delusion of suspicion.

2. The mental disturbance seems to stand in direct relation to the intensity of the pain and tenderness; for if from the first group (87) we subtract 17 cases in which the scalp tenderness only occurred once during their stay in hospital and 8 in whom tenderness was present on the body, only 62 cases remain in which the disturbance of sensation was well marked. Of these 62 cases 59 showed the typical depression and 3 were doubtful; 31 had hallucinations in hospital and 15 gave a history of hallucinations before admission; 32 showed the delusion of suspicion, and 3 were doubtful. On the other hand, of the 17 cases who only showed scalp tenderness once during their stay in hospital, 1 showed the depression, none had hallucinations, 3 gave a history of hallucinations, and none showed the delusion of suspicion. Of the 8 who exhibited tenderness of the body only, none showed the depression, none had hallucinations, 1 gave a history of hallucinations, and none showed the delusion of suspicion.

3. Local pain, whether associated with deep tenderness or not, is not associated with these mental changes. Eight cases of pleural pain showed none of the above-mentioned mental changes. One case passed through a pleurisy without mental change, but some weeks after developed the typical mental changes in association with definite referred pain—not local, like the pleural pain—accompanied by superficial tenderness—not deep tenderness, as with the pleurisy—

* BEAN, 1895.
† BEAN, 1896.

* In my two first papers I treated these areas of tenderness mainly from the territorial aspect, giving only such cases as threw light upon the topography or connections of the different areas. The consideration of the clinical significance and value of large groups of areas, together with a full discussion of the part played by anaesthesia, etc., in their production, will form the subject of the third of the series.

caused by the implication of the lung itself by the tuberculous disease. In the same way the local pain of peritonitis causes none of the mental changes I have described above.

4. The depression seems to be associated mainly with the presence of areas over the lower part of the chest and over the abdomen. The hallucinations are only present where scalp tenderness is a marked feature of the sensory disturbance.

5. The clinical conditions which lead to the development of the referred pain and tenderness in phthisis, cardiac disease, anaemia, etc., and why one case suffers from referred pain and mental changes from which another case remains free were hastily treated before the Section, but can only be described in the full paper.

IV. The method of work was then described. Each case was either in the Victoria Park Hospital for Diseases of the Chest or under my own constant supervision for a considerable time (six weeks or more). An elaborate system of notes was adopted, including a careful present state of the nervous system and special senses. All the notes were taken by myself, and the diagnosis of the physical condition assured by the valuable aid of my colleagues, to whom I wish to return my sincere thanks. Charts of the sensory changes were repeatedly taken. The occurrence of any fresh mental change was the basis of a careful present state, whilst the special senses were re-examined with every hallucination.

I wish to return my sincere thanks to the medical staff of the Victoria Park Hospital for the extreme liberality with which they permitted me to use their cases not only during my period of office as house physician, but also after my official connection with the hospital had ceased. My especial thanks are due to Dr. Sainsbury, Dr. Chaplin, and Dr. Colbeck for the infinite pains they took to assure the correctness of the description of the physical condition in different cases.

A DISCUSSION ON INSANITY IN RELATION TO CRIMINAL RESPONSIBILITY.

Introduced by HENRY MAUDSLEY, M.D., F.R.C.P.,
Consulting Physician, West London Hospital.

In opening a discussion on insanity in relation to criminal responsibility, I cannot help feeling that the task which I have undertaken is as likely to be as barren of profit as of novelty. There is little, if anything, to be said that has not been said over and over again, and will not have to be said over and over again. For, in spite of its proved unscientific basis and its condemnation from time to time by eminent judges, the legal criterion of responsibility is still in full vigour.

There are few, if any, medical men having practical knowledge of the insane who would assent to the proposition, understood in its natural sense, that an insane person is fully responsible for what he does when he knows the nature of his act, and that it is a wrong act. The saddest cases of melancholic anguish to be seen are those in which the sufferer is tormented with a horrible impulse to do, and perhaps does, what he knows and loathes as wrong; the driving impulse in him so strange and contrary to his true nature and desire, so repugnant yet so compulsive, that in olden times it seemed explicable only as a positive possession by the devil or other evil spirit. As I have said of it elsewhere, the basis on which the legal criterion rests is simple enough—that a man in convulsions is a strong man, and is culpable if, being conscious of them, he does not stop them. Consciousness of is assumed to mean power to control, the mad impulses of a deranged mind: a will insensible to the influence of legal sanction to be the same thing as a will capable of being influenced by it. The theory would have exacted from the man who knew himself possessed by the devil, and thus dispossessed of himself, that he should possess himself all the same and master the devil in him, or else suffer punishment for the devil's doings. A rather unequal contest that: the man against the devil, with the devil in possession of the citadel of the man's being. Put the word disease in place of the word devil, and you have the exact situation of the modern madman in relation to the legal test.

The test has its foundations, however, only they are laid in wrong observation and bad psychology. The observation

is self-observation by sane minds, and its natural result is the fixing of a sane standard of feeling and action as the measure of insane feeling and action. Could anything be more absurd? Surely the right method would be self-observation in abnormal, not in normal, mental states—in dreams, in hypnotism, in allied disintegrated states; their mental disintegrations furnish the proper standard of comparison for the vagaries of insane thought and feeling. Now I venture to say that no one who reflects sincerely on his own experience in dreams, remembering how strangely he thinks and feels in them, and how entirely he loses possession of himself, can believe that a madman is responsible for what he feels and does in the waking nightmare which madness sometimes is.

Then again the psychology of the legal test is at fault. It assumes, at any rate its defenders sometimes assume, that reason is the motive force of human action—that is to say, for example, that people fall in love from reason, and, when in love, embrace from reason, and after due embraces, proceed further in the business from reason. Is not that again a pretty absurdity? How many times has feeling its reasons which reason cannot fathom. The driving impulse by which men are moved to act comes from feeling, not reason; disordered feeling, therefore, is quite capable of actuating the most disordered action without consent of, perhaps directly against, reason. Had mankind been moved by reason in their travel through the ages, they would not have been where they are now. For it is in the heart, not in the head, that their deepest faiths are rooted; and he does an ill service to religious faiths who strives to base them on the feeble apprehensions of human reason. A psychology which finds the motive power of action in knowledge might be likened to a science which should find the cause of the tidal movements not in the moon but in the moon-shine.

But it may be contended that reason, though it supply not the motive force of action, can still control and guide it. That is so no doubt within measure. Let reason and feeling be wed in fit harmony, if possible, since they are the two elements of will, and cannot do without one another, reason without feeling being impotent to act and feeling without reason being tyrannical in act. It is not true, however, that reason can always control the desire when it knows its good or bad quality and can appreciate the right or wrong of it. A mad desire is sometimes mad enough to have its convulsive way in defiance of reason. Nevertheless, though that is what experience says plainly, legal theory will not have it so; it maintains that when reason fails to check a mad desire it is not sound reason really, knows not then truly what it seems to know and thinks it knows; the person had not actually the unanted consciousness of right and wrong in the particular case on the particular occasion. His act fell short of being a full crime, not because reason did not consent, but because reason was so infected itself without knowing it as not to dissent effectually. To save a beloved theory we are asked to give a large and liberal interpretation to the word "know," to make it mean what, on the face of it, it does not mean, and to read into a person's consciousness a violation of which there is no evidence—to say, as the late Sir James Stephen would have us say, that if a man cannot control himself he does not properly know the nature of his act. So far as this somewhat strained subtlety of interpretation serves to prevent a madman from being punished for a crime which not he but his madness has done, it deserves praise; but when it operates to get him punished for what his madness does, to get him hanged perhaps for being mad, it is not so praiseworthy. The test is too metaphysical for use, even if it were true.

No person, however acute, can dive into the depths of another person's mind and know, what he does not know himself, how far his consciousness of right and wrong is vitiated on a particular occasion; and it is certain that when a common jury is asked to make the delicate appreciation they are not likely to trouble themselves with a subtle metaphysical interpretation. They will understand it in rough-and-ready fashion to mean that if he knew what he was doing, not the quality of what he was doing, he was responsible.

Why, then, maintain a test so hard to understand and so easy to misunderstand, so false in science and so uncertain

in application, so often interpreted in different ways by different judges, and not always interpreted twice in the same way by the same judge? Why wrongly bias the judgment of the jury by an express prejudgment of facts which ought to be left impartially to them to weigh and judge? Such a prejudgment is essentially prejudice and the legal reverence which it receives no better than superstition.

Moreover, it is a procedure of doubtful legality. For what right in law has the judge to lay down a particular test of disabling mental disease? Is not that a usurpation on his part, an abuse of law? Are not all the symptoms of mental disease and all the tests of its existence and of its degree of existence in a particular case properly facts for the jury? If so, the express imposition of a special test is an interference with the province of the jury, and, as Mr. Justice Maule foresaw when he dissented in the famous conclave of the judges, prejudicial to a fair trial. What the judge does by imposing his test is to instruct the jury wrongly on a matter of fact which it is their function, not his, to judge; by an allegation of fact which is not fact, he gives false evidence as a witness without submitting himself to cross-examination. A particular test of disabling insanity is no more a matter of law than the test of a particular poison; it is rightly a matter to be proved in evidence in the particular case, like other relevant facts.

So far from being a help to the jury in a difficult inquiry then, the judicial dictum confounds and misleads them. Were the court sincerely minded to help, it might do it in a better way than by a difficult and dubious test of disabling mental disease. It might take means to inform the jury fully and truly concerning the nature of the particular form of mental disorder in question and the extent of its damaging effects on the mind, either by providing them with impartial and competent scientific evidence, called by the court itself, or by appointing a competent scientific authority to assess the value of the scientific evidence given. To a body of men who understand not even the terms used, the opinions of opposing experts which a competent assessor would easily estimate at their proper value, are equally valuable or valueless. What an absurdity it would seem, had not custom made it seem natural, as custom will make anything natural, to expect a judge and jury, ignorant of the very elements of chemistry and electricity, to be so adequately instructed by what they hear during the course of a trial as to decide rightly a difficult question of chemical or electrical science. If it be a question of navigation when two vessels have come into collision, about which every jurymen who has been in a boat might be expected to know something, the services of a skilled assessor are called in; but if it be a question of complex science, of which the jurymen know absolutely nothing, it is left to the intuition of ignorance to give understanding. What is the result? That the issue would be decided quite as justly, perhaps more justly on the whole, by the toss up of a penny, without the tedious solemnity of wasted talk and time.

Of the judicial test of responsibility in particular, and of the method of legal procedure in general, we may justly say that they are very ill-fitted to find out the truth, very well-fitted not to find it out. In summary, the charges against them are these:—

1. The court has no more right in law to set up a special test of responsibility in a case of mental disease than to set up a particular chemical test in a case of poisoning.
2. To do that is really to give important evidence to the jury without permitting the evidence to be cross-examined or contradicted.
3. The evidence so given is bad, for the test is wrong in fact, and based on unsound psychology.
4. It can be made decently workable only by construing it in a non-natural sense, and ordaining that words which say one thing clearly shall mean another thing obscurely.
5. The court makes no provision to obtain impartial scientific evidence, but requires or allows the parties in the case to ransack the medical highways and byways in order to obtain contradictory evidence with which to confound a jury ignorant of its meaning.

This condemnation of the present system of procedure may claim the assent not of medical men only, but of the common sense and conscience of the community, which, after all,

is actually in a sort of tacit rebellion against it. For what happens now when a person about whose mental state there is some doubt is condemned to death? Why, that the competent medical knowledge is summoned to give the impartial help which ought to have been given at the trial—perhaps to undo quietly in private the wrong which has been done with all the pomp of justice in public. Nay, more; I notice from time to time nowadays that an insane person accused of crime is not put on his trial at all, but that someone in authority has, or usurps the right to have, him examined medically and sent to an asylum. Thus is the Englishman robbed of what he cherishes as his blessed privilege—the right to be tried by a jury when he is charged with crime. On mere medical evidence that he is mad he is shut up for life because of an offence for which he can never get himself tried.

So much by way of criticism from the medical standpoint. Now let me try to look at the matter from the legal standpoint. Lawyers think that medical men are too ready to discover insanity when crime has been done and to claim irresponsibility for everybody who suffers from any sort and degree of insanity—in fact, to make all crime insanity, not entirely without excuse. They judge by what they see in courts of justice; and what they see is that there is no case, however weak and indefensible, that does not, for some reason or other, obtain medical support. They put down, therefore, to unsound medical theory what is really unsound medical evidence—which, obtained, perhaps, by hook or crook under the present fashion of procedure, any competent medical authority would assess and reject as worthless. They hear the opinion of him who presses forwards to give it; they do not hear the opinions of those who, having been urgently asked, refused to give it. Naturally therefore they conclude one of two things: either that there is no such thing as exact medical science or no such thing as exact medical honesty. The result is that expert scientific evidence, which should be decisive, has the least credit of any kind of evidence given in a court of justice. For this discredit the law is not to blame; its blame is that, knowing the weakness of human nature, it maintains a system of procedure which makes it inevitable.

Another circumstance which justifies legal criticism is the common medical habit of discussing the question of responsibility in relation to insanity in the abstract, as if insanity were some definite and constant entity, something which is altogether or not at all, and, being there, ought rightly to exculpate entirely. One might just as well discuss whether bodily disease in the abstract ought to prevent a man from walking ten miles a day. The truth, of course, is that there is no such definite morbid entity as insanity—that there are really as many insanities of mind as there are degrees and kinds of derangement of it. It is with insanity in the concrete and particular that we have properly to do; and, just as one bodily disease ought and another ought not to prevent a man from walking, or from doing one thing while he may do another, so one insanity of mind abolishes entirely a responsibility which another does not. The right question is the disabling effect of the particular mental disorder in the particular circumstances—a question to be decided by full, impartial, and competent consideration of all the facts of the case, by a consideration, that is, fully instructed to appreciate their nature and bearing, not as now by incompetent consideration expressly instructed.

Time would not serve now to discuss the degrees of disabling moral and intellectual damage done by the various forms of mental disorder, some of which after all are not so much states of actual disease as bad habits of thinking and feeling grown into deformities. What I venture to make here is a protest against the assumption that insanity in the abstract, meaning thereby all insanities of whatever sort and degree, should of course be deemed irresponsible. And I take or make the occasion to utter another protest—a protest against the lamentable extravagance into which the latest school of criminology has been betrayed. I should be loth to say a word to discredit the scientific method of studying crime and criminals or to disparage for a moment the good work which has been done; but of unripe observations and sensational theories I hope it is not too much to say that, though they make the vulgar stare, they make the judicious

grieve. Science on the platform, like philanthropy on the platform, runs no little risk of demoralisation; the performers are under a strong temptation to play to the gallery and to burlesque science.

To say that there is a criminal nature which is degenerate is one thing, but to go on to say that all criminals are degenerate and bear the stigmata of degeneracy is another and, I think, quite false thing. I do not see why crime should necessarily be degeneracy. I can conceive a murderer being a nobler animal than a saint of the Pecksniffian sort. A murderer on a big enough scale, big enough to despise the fools whom he uses and sacrifices for his ambitious ends, is he not a hero? Criminals there are certainly who are defective in structure and conformation, of body and mind, beings who, if not protected against themselves, must go wrong. There are criminals, again, who are more or less insane in the statutory sense, and are explained or excused by their insanities; but there are criminals also who, in other circumstances, might perhaps have been as great saints as in the changes and chances of things they become great sinners. For assuredly the external factors of circumstances count for much in the causation of crime; time and chance happen to all men, and no criminal is really explicable except by a full and exact appreciation of his circumstances as well as his nature, and of their mutual interaction. For my part I sometimes wonder whether the new school of criminology would have found the stigmata of degeneracy present in Saul, the fiery persecutor of the early Christians, and found them gone when, transformed from iniquity to holiness, he became Paul, the great apostle of the Gentiles.

Has not the theory of degeneracy been abused of late? As used by Morel the term had scientific meaning and value, but much has been done to rob it of definite meaning by stretching it out to cover all sorts and degrees of deviations from an ideal standard of feeling and thinking, deviations that range actually from wrong habits of thought and feeling to the worst idiocy, and some of which are no more serious marks of morbid degeneracy than long legs or short legs, long noses or short noses. Moreover, as often happens with big-sounding words that have no definite meaning, but are used habitually as if they had meaning, the meaningless name has been converted into a quasi-metaphysical something, so that many persons think, when the word degeneracy has been spoken, that all has been said that need be said, though nothing actually has been said.

To me it seems that the conflict between law and medicine might soon end if words and theories were swept aside, and the facts dealt with on their merits. Let the lawyers renounce unreservedly their discredited test of disabling mental disease, and submit all the facts in a particular case impartially to the jury. Medical men on their side should discard the notion of insanity in the abstract, and leave off talking of it as if it were something definite and constant, which annulled all responsibility. To place before the court as plainly as possible all the facts of the particular form of mental derangement in the case; to explain what they mean according to the best scientific information, and how far they affect the mind; and to leave it to judge; that is our proper medical function.

The question of legal responsibility is a legal, not a medical, question. As witnesses, we have nothing to do with the right or wrong of the law, though we may properly criticise it as citizens. The business of every society is to protect itself, and it has the right, which is the right, to make what laws and to inflict what punishments it thinks best for its own protection—to hang for theft or flog for fornication, if it likes. Naturally each society will think its own laws and punishments the more right, other laws and punishments less right. But be the enacted law right or wrong, the individual, in whatever social medium he is placed, must obey it or suffer the penalties of disobedience: he lives for the society, not the society for him, and, living for it, he must die for it, even though he be mad, if it think fit.

What, then, as the conclusion of the whole matter, is there left for us to do? So far back as I remember we have been criticising the legal test of responsibility, condemning it by formal resolution, petitioning for commissions of inquiry into it, demanding its abandonment; yet we are still voices

crying in the wilderness and doomed apparently to go on crying. However, we have made some way; we have seen it condemned by the best, magnified only by the worst, judges; and we have had an interpretation of it by the late Sir James Stephen which, if it does not radically change its meaning, makes it include practically all we ask for. If it really include not only (1) knowledge of the nature of the act, and (2) knowledge that it is wrong, but (3) control of conduct, it is a pity that all judges do not understand it properly; a pity, too, that Sir James Stephen did not take steps to have his construction of it tested, as he might have done in a way suggested by himself, that is, by expressly directing the jury according to it in a particular instance and then stating a case for the Court for Crown Cases Reserved. Perhaps, knowing the conservative tenderness of the judicial mind, he feared to jolt but hoped to infiltrate it. One may suspect that he himself, though direct and thorough in thought about some things, still in legal matters loved the good old way of the English mind—to keep the old names when the meaning has been taken out of them or a quite new, perhaps opposite, meaning put into them, to accept the gradual dissolution of the substance of a belief so long as the label of it is left intact.

The President said they must all be delighted at the intellectual treat which they had just had, and proposed a vote of thanks to Dr. Maudsley, which was carried by acclamation.

Dr. NICOLSON said this was an occasion on which to be congratulated at Dr. Maudsley coming out amongst us once again. In him we have an expression of the soundest judgment. He looks the matter straight in the face unbiassed, and has put our position and views in a nutshell. What he has put before us leaves little to argue about; it is so fraught with common sense and judicial consideration that it must have its effect on all of us. Dr. Nicolson thought we could not be too careful in dealing with each individual case separately. He thought that there would be great danger in allowing prisoners to be examined and cross-examined in their cell, and he deprecated the admission of the wife's evidence as to the prisoner's guilt or sanity. He considered the tests given to the jury unsatisfactory, but entered a word of warning against any alteration in the present mode without due consideration.

Dr. URQUHART was glad that Dr. Maudsley had not laid down any new law. He was of opinion that the question of the prisoner's state of mind would be better left to the Court for Crown Cases Reserved.

Dr. MERCIER said if they wanted the law altered reason would have to be given and special cases quoted in which actual injustice had been done, and he challenged those present to show a single case in which actual injustice had been done. As a member of a special committee to inquire into it he had come to the conclusion that there had been none for many years past. Under the present conditions he considered that actual facts were submitted to the jury. He quoted a case, lately before the Court, to show the latitude medical witnesses are given at least before one judge, and thought medical men were seldom tied down to the mere word of the law.

Dr. WEATHERLY characterised the address as being one of the ablest ever given before the British Medical Association. He thought that each case should stand on its own merits. It should not only be proved that the man is a lunatic, but that his act is the outcome of his lunacy. He holds that if justice is done to the man it is done in the condemned cell, but as it is done there, and not till he is there, it shows that injustice was done to him in the court of law. A man insane at the time might be quite sane after he is condemned. Much has been said on capital charges, but there are many persons found guilty of minor offences and punished, in which there was a total absence of moral responsibility. He thought it too often largely depended on the judge before whom the prisoner was tried.

Dr. NORMAN KERR said that up to 1867 persons who had committed a crime while under the influence of delirium tremens were hanged, but quite recently Mr. Justice Hawkins had allowed this to justify exemption.

Dr. SAVAGE said: "I think more attention might have

been paid to the scientific part of Dr. Maudsley's paper. I quite feel that man is as much or even more a feeling than a reasoning animal. Lawyers rather want to gauge actions the outcome of feeling by the rule of reason. We all seem agreed as to the importance of getting rid of the definition or test of knowledge of right and wrong as the test of responsibility, but do not let us substitute any other definition. With Dr. Orange, I do not believe in criminal insanity, but in criminal lunatics, and each person must be measured by his own standard, and not by a standard of what is insanity in the abstract. English society will never admit medical assessors to take the place of English juries, and the one important thing for us to aim at is to get the facts indicating insanity fully laid before judge and jury, not as partisans but as witnesses of truth; judges will differ, and we must put up at present with their peculiarities in accepting expert evidence, and I agree with Dr. Weatherly that much is to be desired on this point. I do not agree with Dr. Norman Kerr that all, even temporary, insanity will ever be accepted as a saving clause of all acts done by a patient. That a person believes the moon to be made of green cheese will not be accepted as a reason for murdering his grandmother; yet if sufficient evidence is given some relationship may be traced, and the medical witness ought to be able to lay clearly before the jury his views. We doctors are not infallible, and we must be prepared to let the jury fulfil their function. We have had an admirable paper and a good discussion."

Dr. CLOUSTON differed from Dr. Mercier in that no case of injustice had been made out. He thought that about half of all criminals solemnly tried and condemned to be hanged were afterwards made out insane, and relegated to Broadmoor. He described the method gone through in Scotland, and said that a murderer found insane was sent to an ordinary asylum. He thought if gaol surgeons were properly instructed in insanity, fully half the scandals would be avoided. He agreed that the personal equation of the judge should be left out altogether. Thought criminal lunatics should not be sent to Broadmoor during her Majesty's pleasure, as many cases were curable in a few months, whereas they were now detained for the rest of their lives.

Dr. NICOLSON took exception to this last remark, and said that they did not remain at Broadmoor their whole life, and that they had from six to eight discharges in the course of the year. Also, after looking up the point, he said that instead of 50 per cent. of those committed for murder being reprieved, the actual percentage was 5.6 for a period extending over 30 years.

Dr. SHUTTLEWORTH wished to make a few remarks on cases of arrested brain and mental development involving the mental faculties. Dr. Shuttleworth had experienced no difficulty in bringing under the notice of the judicial authorities the abnormal mental condition of the accused, and he quoted a case in which Sir James Stephen put it to the jury whether the accused was capable of pleading or not, and on his (Dr. Shuttleworth's) evidence discharged the boy to the care of his father, binding him over to produce him for trial when he should become capable of pleading. The difficulty in these cases was that with great moral deficiency there is sometimes but little intellectual deficiency; and it might be a question as to the degree of knowledge of right and wrong a patient possessed. Dr. Shuttleworth did not hold the view that a slight degree of imbecility should exempt from all punishment. He urged that much depended on surroundings and training, and many cases of imperfect and arrested development drifted into crime because their environment was unfavourable, and the necessities for special training not understood.

Professor VON BARNEDIKT referred to the place alcoholism and sexual perversion took in reference to crime. The question was, Should the man be treated by a medical man or a judge? There were many people, he said, who committed crimes over and over again, and were punished for them, and were not morally responsible. Insanity is a matter of degree, and he believed in partial insanity, which he thought should be recognised.

Dr. USHER referred to the mode of procedure in Australia, and said it was not uncommon for a criminal convicted to call for a Board to examine him as to his mental condition. He can also ask for an examination before his trial.

Dr. OSCAR WOODS thought the law very uncertain, and gave an instance.

Dr. DOUGLAS did not agree with Dr. Mercier in that the law was all that it should be. He thought that it was out of conformity with the views of to-day.

Dr. RAYNER thought that undoubtedly injustice was done in many cases by condemning a man, and then letting him off; and he suggested that the Home Secretary should be asked in Parliament in reference to each case as it occurred. He thought it impossible to eliminate personal equation and the prejudices of the judge.

Dr. MAUDSLEY, in reply, said he thought they were all agreed that the facts should be put straight before the court without prejudice. If judges were only uniform, much difficulty would be removed. He agreed that injustice was undoubtedly done by a parade of justice, condemnation, and afterwards removal to Broadmoor. He thought that judges, as they got older and gained experience, abandoned the right and wrong theory, and placed the facts straight before the jury.

THE SURGICAL TREATMENT OF IDIOCY.

By G. E. SHUTTLEWORTH, M.D.

Formerly Medical Superintendent of the Royal Albert Asylum, Lancaster. CRANIOTOMY in microcephalus having been much referred to both in the medical and lay press as serviceable in promoting brain development in that form of idiocy, it became necessary to examine the evidence upon which such an opinion rested. Tracing the history of the operation with which since 1890 the names of Lannelongue of Paris, Keen of Philadelphia, and Victor Horsley were specially associated, Dr. Shuttleworth argued that the experience of five years did not sustain the sanguine expectations of early operators. As microcephalus was indeed not (as a rule) dependent on premature synostosis, but on original faulty brain development, the operation was never a promising one; and though it was now contended that in some cases a conflux of blood and consequent improved brain pulsations were produced by it, the after-history of cases operated on some years ago did not show more mental improvement than would probably have occurred independently of the operations. Bourneville (of Paris) indeed had demonstrated that such operations in the long run tended to diminish cranial capacity, as exuberant bone growth was apt to take place where bone had been excised. In microcephalic cases more benefit was to be expected from training than from operation. In cases of mental deficiency with pressure symptoms—as in traumatism and hemiplegic cases—there were good indications for operating, and in hydrocephalic and hypertrophic cases of imbecility tapping or trephining might be beneficial. A remarkable case of syphilitic imbecility (inherited) with epileptic symptoms, much benefited by trephining, had lately been reported by Mr. Anderson, of St. Thomas's Hospital. Operative procedures followed by special training might indeed be of use in some forms of mental deficiency in childhood, though not in ordinary microcephalus.

Dr. FLETCHER BRACH agreed with Dr. Shuttleworth that craniotomy is of no use in microcephalic idiocy, and pathological anatomy has shown us that the theory on which it was originally based rarely exists. He believes it of use in those cases of traumatic origin and in those cases of hydrocephalus and hypertrophy of the brain.

Dr. TALYOR-SMITH gave the after-history of a case quoted by Dr. Shuttleworth in which the improvement was very slight, if any. He also said that Professor Cunningham, of Dublin, had found that arrest of development of the brain leading to microcephalic idiocy takes place at fourth month of intrauterine life.

INSANITY OF CONDUCT.

By GEO. H. SAVAGE, M.D., F.R.C.P.

Formerly Medical Superintendent of Bethlem Lunatic Asylum.

Dr. SAVAGE brought forward a number of cases to show that there are many insane conditions in which the conduct of the patient must be the gauge of the disorder, and that, though we do not ignore intellectual and sensory disorders, yet besides and apart from these the conduct of the patient

must be studied and recorded. There is, he said, often more disorder of the conduct than of the speech or writing in the insane. An act may be the symptom of insanity quite apart from any apparent intellectual defect. The law does not recognise this enough. In legal certificates and in the evidence of medical men most stress is laid on words said, and greater latitude should be given for the admission of the history of insane actions. Moral insanity has a real existence, and is a division of the insanity of conduct. Dr. Savage then quoted cases showing that insanity of conduct is well seen in some so-called hysterical cases, in which a young girl sent anonymous letters to a cousin who got engaged, and to other young men, with vague threats and suggestions. She also got untruthful, and had a curious skin eruption, proved to have been produced by herself. It is seen at times in the highly intellectual, in poets, inventors, and in many geniuses. It is seen as a stage of other mental disorder, such as in mania and melancholia. It is seen in degenerative and senile cases. It is seen as a result of chronic insanity. It may occur with some form of so-called monomania, such as kleptomania. On the other hand, he quoted cases to show that there are certain persons whose conduct is perfect, and yet who are defective intellectually. One case, that of a lady, heiress to considerable property, who had been placed under the most favourable conditions for education, was at 21 unable to do the most simple sum or even read, but passed in society as quiet and shy, but not evidently mentally defective.

Dr. MERCIER read a paper on the same subject and quoted a case in which insanity was evidenced mainly—practically entirely—by conduct, and in which disorder of mind, though not entirely absent, occupied an altogether subordinate position. A gentleman, who had had a brilliant career and distinguished himself at college, entered a profession, rose high in it, and displayed abundant evidence of exceptional intellectual attainment. At length something happened which compelled him to retire from his profession. He now eschewed the society of his equals, alcoholic debauches became more frequent—had from his college days been addicted to drinking in a sottish manner—and accompanied by manifestations of sexual perversion. He would leave his home again and again and be found in some disreputable haunt surrounded by youths of the lowest class, and again and again his associates extorted large sums of money by way of blackmail. Upon the most careful examination he was quite uncerifiable. A few facts were, however, important. He wrote numerous letters describing his practices; some he posted to his associates in vice, some he left about the house for anyone to read; and, secondly, in writing a letter on the simplest matter he would fill sheet after sheet. After one of these debauches he was admitted on an urgency order, but the magistrate refused to make a reception order. Subsequently he became the subject of an inquisition in lunacy, and was found insane by the master, there being no real opposition on the part of the patient, whose alternative was a conviction at the Old Bailey. Dr. Mercier maintained that insanity was not a disorder of the mind; that there might be disorder of the mind without insanity; and that in insanity there was much besides "disorder of the mind." At the same time he did not wish to be understood as saying that there can be insanity without disorder of the mind.

Dr. HICKS spoke of the tendencies of some towards acts of misconduct in early life, almost amounting to congenital, and thought more pains should be taken in the bringing up of these cases.

Dr. BEDFORD PIERCE failed to follow Dr. Mercier in making a sharp distinction between disorder of conduct and disorder of mind. He thought the case quoted would be more correctly described as one of disorder of mind in which the disorder was manifested by extraordinary conduct.

Dr. CONOLLY NORMAN also questioned whether Dr. Mercier's use of the word "mind" was not too limited. He would prefer to substitute the term "intellect" or "intellectual powers." Dr. Norman referred to a case in which perpetually repeated acts of bigamy constituted the main evidence of mental aberration.

Dr. HAYES NEWINGTON thought a great test of sanity was whether they could rightly take in what went on around them in everyday life.

A DISCUSSION ON THE RELATION OF EPILEPSY AND INSANITY.

Introduced by W. R. GOWERS, M.D., F.R.C.P., F.R.S.,

Physician to the National Hospital for Paralyzed and Epileptics.

IN undertaking to open the discussion on the relation which exists between insanity and epilepsy I have regarded the task in the literal sense of the words which designate it. That which I felt I could safely undertake to do and that which I propose to do is to break the pre-existing silence, which must be broken in some way, by some person, that discussion may occur. Although a discussion is proposed I conceive that I am also safe in saying that the object in view is not discussion but information. It is fortunately not necessary for me to give information; if I can indicate some points on which knowledge can be supplied by others I shall feel that I have done my duty. That which we need to know cannot be discerned from the side of epilepsy. Mental derangement, for the most part, at once withdraws a patient from the eyes of those who observe the disease from the other side. The essential facts regarding the epilepsy associated with insanity are for the most part within the reach of those under whose notice the insanity brings the patients. It is from them and from them alone that the needed knowledge can come, for the facts regarding the insanity are outside the range of vision of those who can study the associated malady. Hence, from the side of epilepsy, we can see what knowledge is needed, we can feel keenly the want that can only be supplied to us, and I conceive that the most useful result this discussion can have will be to promote the collection of such facts from an area sufficiently large to give them the strength which extent and combination alone can secure. This result may seem to be trifling. In truth it is all-important. For information to be gained by seeking it is essential that the search should be definite. The object must be in view to make observation useful. To gather at random is to waste the energy that might yield precious facts.

We must, I think, restrict our consideration of the subject to idiopathic epilepsy, and exclude from our view all the cases in which organic brain disease, in early or adult life, produces both convulsions and mental derangement. Within this limit there is enough, and more than enough, to be discerned. I hope some definite addition to our knowledge may be forthcoming to-day from those who bring here their asylum experience, but I hope that far more extensive knowledge will be gained by future prearranged observation. The information that is needed can only be obtained from many observers. Associated effort, such as may be the result of our meeting, can alone yield the knowledge that we need.

Epilepsy and insanity are alike disorders of the cortex of the brain, the result of changes in finer nutrition which have yet to be discovered, if their discovery is possible. I speak thus hesitatingly, because I am satisfied that, as regards epilepsy, no alleged pathological observations are true, and least of all those which at one time led the name "epilepsy," in the reports of the Vienna Hospital, to be changed to "disease of the cornu ammonis." If the recent extension of our knowledge and of our conceptions of the central nervous system is trustworthy, and trustworthy it seems to be, we have never yet looked in the right place for the morbid changes which may underlie either the one disease or the other, and we have not yet reached even the position whence we can attempt to look for them. According to these conceptions, it is in the spongy grey matter, in the interlacing network of fibrillæ which intervenes between the cells, in which their branching processes end, it is in this that all nerve energy is elaborated, that all ordered action arises, and that all disordered action is produced. Pathological anatomy must be relegated to a future day, and, for the present, we must study the subject, and can study it only, from the clinical side.

The first great fact of the relation between two diseases is their family interchangeability. This is less remarkable perhaps than it seems to be when we think of epilepsy only as a motor symptom. If we consider the frequency with which a sensory aura shows that it is in the sensory structures that the discharge begins, and if we consider the extreme frequency of minor attacks in which only loss of con-

sciousness reveals inhibition of the structures related to psychical processes; if we consider also the elaborate psychical character of many of the higher sensory warnings, I think it will be felt that the range of functional disturbance of epilepsy must include some part of the functions, the derangement of which, in another way, causes insanity. The extent to which insanity is to be traced in the families of those subject to epilepsy is approximately known. The extent to which epilepsy can be traced in the families of the insane is, I think, not yet known. It can only be known by combined observation, and this is one of the points which I think deserves combined effort—to ascertain facts upon an adequately large scale. We need to know, not only in what proportion of cases epilepsy can be traced, but also in what proportion in the different forms of insanity, and we need farther to know its relation to a history also of insanity in the family, and also if any relation can be discerned between epilepsy as a family antecedent, and the course of the forms of insanity in which it occurs.

I can only offer you some facts regarding the extent to which insanity can be traced in the families of the epileptic; but I would impress strongly the importance of taking heed to the source of all information regarding inheritance, and indeed of separating the facts according to their source. The importance of this has been impressed on me in an emphatic manner by investigation of an additional series of cases of epilepsy for a new edition of my book on the disease. There is a tendency to concealment of hereditary disease among the upper and middle classes which is definite, but its influence is small compared with that of simple ignorance among the lower classes, who constitute the bulk of our hospital patients. The statistics I published in the first edition were almost exclusively drawn from hospital cases. Of the second series, almost the same in number, now investigated, about a third were seen in private. The comparison of these with the rest is instructive.

Inheritance, epilepsy or insanity, was traceable in the first series in 35 per cent. In the second series the proportion was 44.5 per cent., but in the cases of this series seen in private the proportion was 48.4 per cent., or nearly half. But this, we may be confident, is below the truth, and that at least in one-half of the cases there is inheritance. The lesson is that statistics regarding inheritance taken from cases in lower classes are at least 30 per cent. below the truth, that one-third ought to be one-half, and that it is essential that the cases collected should be separately considered according to the position in life of the patients.

I mention this general fact on account of its importance, but we are now concerned with insanity only as an antecedent of epilepsy. It is an interesting fact that, in my second series, although inheritance was traceable in so much larger a proportion of the whole, the proportion of the cases with heredity taken separately in which insanity could be ascertained is almost the same as in the first series. In each insanity had occurred in the relations of one-third of the cases in which there was evidence of heredity; while epilepsy existed alone in two-thirds. In the first series inheritance was traced in 439, in the second series in 437. These two sets of cases, with inheritance 439 and 457, are nearly equal. In the 439 cases, insanity was heard of in 157; in the 457 cases, insanity was heard of in 170. The proportion in the first series was 33 per cent., in the second 37 per cent. I think that the fact that the great increase in the proportion of heredity, due to better information, is only attended with a slight increase in the proportion of insanity, is a striking indication of the general trustworthiness of these facts. This is the more satisfactory, because we are absolutely dependent upon the statistical method for such knowledge.

I am sorry that I can give no information regarding the features of epilepsy as it occurs with or without insane heredity. The converse facts, the character of the insanity in the cases with epileptic history in relation can be given, I doubt not, from asylums in the course of time, by carefully collected and carefully sifted observations.

The actual association of epilepsy and insanity in the same individual, as a subject of observation, requires careful limitation, and I think that one object of this discussion should be the discernment of the limits within which information may be wisely gathered. The simple mental fail-

ure which results from epilepsy, or which is due to the defective development of the brain, qualitative or quantitative, which is the cause of epilepsy, should, I think, be left out of consideration. Only the cases of definite mental derangement should be admitted, and it is not generally difficult to draw the line between the two.

Post-epileptic mania constitutes an entirely separate form, and it is most important to keep it distinct. It seems to represent the post-epileptic hysteroid state which is so common, and which I long ago described as resembling, in its rapid changes from manifestations of terror to those of aimless rage, as "compressed mania." But it is a transient incident in the course of the disease, definitely related to the epileptic attack. It urgently needs study—study it can obtain only from the asylum side, because there alone the severer cases are observed. We need to know more of its causal conditions, of the age of its development, of its constancy, whether it occurs in women in definite form, and its relation to a social position. We need a large number of facts, compared, digested, and combined. I can myself recall no case of post-epileptic mania in a woman, such as that with which you are so familiar, and such as was illustrated by the case I mentioned at the annual dinner of our hospital, in which our valued colleague, Dr. Ferrier, was an involuntary subject, happily with impunity, of a homicidal demonstration. Moreover, I can recall no case of post-epileptic mania seen in private, common as is harmless automatic action.

The explanation of attacks of epileptic mania which is commonly accepted is that given by Dr. Hughlings Jackson, that they are the result of the unrestrained activity of lower centres, consequent on the temporary withdrawal, by the slight epileptic discharge in the higher centres, of the normal control. While accepting and adopting this explanation, I have always felt hesitation in regarding it as the whole truth, or indeed as more than a recognition of the superficial relation of the phenomena. I have met with cases in which it seemed impossible to recognise epileptic phenomena preceding the mental state. I think the study of these cases from the side of insanity will confirm the position taken by Dr. Jackson that the slightest the epileptic discharge, that is the more extensive the function undischarged, the more manifest and elaborate is the post-epileptic automatic action. But we cannot, I think, separate these cases from those in which hysterical convulsion succeeds the epileptic fit, the sequence which, in our own country, is all we can discern as the equivalent of the so-called "hystero-epilepsy" of the French. Moreover, we cannot distinguish minor attacks of epilepsy which are followed by such symptoms, and those in which a normal state is instantly resumed.

This justifies the inference that there is a predisposition on the part of the lower centres to pass into a state of morbid activity. Indeed the same inference is justified by the fact that the hysteroid symptoms which follow such attacks occur almost exclusively in women during the first half of life and males during the first third of life—a proof that a powerful predisposition, a state of arranged latent energy, underlies the symptoms. But we can go further. The commencement of many epileptic fits, especially of minor fits, consists of a psychical disturbance, often associated with activity of a special sense centre. I have mentioned elsewhere the case of a patient whose warning was a sudden vision of the whole of London in ruins, of the River Thames emptied to receive the rubbish, and of the herself being the sole survivor of the inhabitants. We have here a mental state only distinguishable by its brevity from delusional insanity and from the mental state which may succeed a fit. Although it is customary in epileptic fits for the less elaborate to precede the more elaborate, instances of the opposite order are not uncommon. If the epileptic discharge can thus begin by an elaborate mental process, we should be prepared for any evidence that it may consist solely in such a process, and that brief insanity may sometimes be truly epileptic and not merely post-epileptic.

Next to inheritance, the aspect of the relation of insanity and epilepsy which seems to me to be of most definite importance for consideration is the occurrence of insanity in the course of epilepsy. Some epileptic patients pass into a state of definite insanity, usually transient, generally, I think,

taking the form of subacute mania, although occasionally presenting a form of dementia with or without delusions. I use these words with hesitation, but that very hesitation is my justification, because it illustrates the need for information that can only come from asylums. It is especially in these cases that the mental derangement at once withdraws the patient from our observation. I cannot help suspecting that the cases of this character are not adequately studied in asylums.

During my twenty-five years' work at the Queen Square Hospital a considerable number of my out-patients have had such attacks, but never once have I received a letter of inquiry from the asylums in which they were placed, and if I have heard of the attack it has only been when attendance was resumed long afterwards. I wish much that there were more co-operation between those of us who are fortunate or unfortunate enough to be outside asylums and those within them. But the hand must be stretched out from the inside, because for the most part we never know when our hospital patients pass into seclusion, and the opportunity for minute personal observation such as we can never have, is possible only to asylum workers. We miss them for a few months, and then learn to our surprise that there has been an acute attack of insanity. I am quite sure that there is not a single physician, at least at the Queen Square Hospital, who would not be most glad to give to the medical officer of an asylum to which a patient had passed all particulars of the case, and thankful to receive in return some information regarding the attack. These cases seem to me those to which attention should specially be turned, and we need to know the character of attacks, the character of heredity, the relation to age, and especially the relation to previous post-epileptic disturbance.

Another feature needs discernment. It is the precise features of the epileptic attacks in those who undergo these attacks of insanity. It is of extreme importance, because if a definite relation can be ascertained the danger can be to some extent foreseen. I can speak with no confidence on the subject for the reasons just mentioned. But I have a conviction that these attacks of insanity occur especially in those patients whose epileptic fits, true and characteristic, are preceded by psychical or psycho-sensory aura. I have described instances of this elsewhere and need not detain you with them. The instances which have come under my knowledge make me suspect that a considerable number of cases of which I have seen with such aura have, since I took the notes, come under the care of my alienistic brethren. Here again it could only be through their help that this could be ascertained.

Of permanent insanity in cases of epilepsy I know nothing from personal knowledge. Here also the same cause is manifestly effective; but, at the same time, I feel that my own ignorance may be my own fault. It may be that many facts of the class I have indicated as useful have been already gathered and published, and that I might be familiar with them had I taken the necessary trouble to search for them and to find them out. The knowledge that it is so will be welcome. Yet such questions as those to which I have referred illustrate at every turn the truth of the law that observations have little weight that are not specially observed.

You may remember how universally the relation of syphilis to tabes was denied at first on the strength of statistics from old case books, made in routine way without thought of the special point; and you may also remember how those who, on such ground, were most strenuous in their denial of the relation found that facts specially ascertained were absolutely convincing. So it is ever. An object can seldom be reached that is not in view from first to last from the path that leads to it; and I shall deem this discussion rich in result if from it the object to be gained becomes distinct and the footsteps of many tread down a path thereto.

The President congratulated the meeting on having such a distinguished exponent of the subject. He asked them to pass Dr. Gowers a vote of thanks for his able paper, which was carried with acclamation.

Dr. Fletcher Braith thought that on going carefully into

the histories it would be found that inheritance alone was not sufficient to produce epilepsy or insanity, but that many causes acting together produce the result. He agreed with Dr. Gowers that the statistics obtained from the lower class were not so reliable as those from the class seen in private practice. He also agreed with Dr. Gowers on the importance of co-operation between neurologists and alienists. From the want of this various facts are, no doubt, overlooked, and he was of opinion that means should be taken to bring these two classes of the profession more together. He attributed the fact that patients had been admitted into asylums without it being known to the Superintendent that they had formerly been under the care of Dr. Gowers, due to their being often brought by the relieving officer.

Dr. HYSLOP said he thought there was danger in making one's notion too wide as to what was meant by epilepsy. At the present day many conditions of an epileptiform nature were included as forms of epilepsy. From Dr. Hughlings Jackson's scheme of evolution and disolution it is difficult to understand the nature of the positive psychical symptoms met with in epilepsy. We can, he said, readily conceive that brain disturbances may determine losses of local memory, and this would correspond to the negative lesions of Hughlings Jackson, but the mere existence of a negative lesion does not in the least explain the nature or origin of the positive morbid symptoms which are thought to be due to evolution going on in the undamaged remainder. When we confine ourselves more particularly to the consideration of the negative lesions and their effects we find that we have to deal with disorders of memory and, synonymously, therefore, with the comparing faculty. From a clinical point of view, however, we cannot reconcile or adopt the possible existence of a negative brain lesion with the mental symptoms of the insane. In epileptic states of the slighter variety we can readily conceive that local brain disturbances may give rise to temporary or local amnesias, but we do not in the least understand the methods whereby the positive psychical symptoms come to have their origin and abnormal character.

Dr. MERCIER said there were 1,300 epileptics annually admitted into the asylums of England and Wales. He remarked on the cases rarely seen outside asylums, cases of *petit mal*—cases in which the fit is preceded by elaborate aura or followed by elaborate automatic actions. A sister society had recently resolved to make an investigation into the facts of epilepsy by the combined method, and he suggested that it would be of immense advantage if Dr. Gowers would indicate the lines on which an investigation could be profitably conducted.

Professor VON BENEDIKT said he saw many cases which were not recognised as epilepsy, but rather as a vice or passion. It was those cases out of the common which were overlooked. He quoted a case of a man who had a fit whenever he took alcohol. He considered the question of an aura a very important point as, if there is a definite one, they do not require such constant supervision.

Dr. HUGHES thought enough clinical observation had already been made to prove the unvarying kinship between all epileptoid states and what we have been accustomed to regard as true epilepsy. He considered *epilepsia mitior* and gravior practically the same though clinically varying in their symptomatic expressions. He thought Dr. Hughlings Jackson had done much to elucidate the obscure cases of *petit mal*.

Dr. CONOLLY NORMAN was surprised to hear that Dr. Gowers had not seen cases of post-epileptic mania in women. The speaker had seen several such, and in one woman recently under his care attacks of epileptic mania regularly followed attacks of *petit mal*. He said that epilepsy with highly organized aura are probably followed by insanity with undue frequency. He had seen in an asylum the case referred to in Dr. Gowers' early edition of his book on epilepsy, and he was suffering from what Korsakoff had called *dysnoia*, and which the speaker had described as acute confusion. He remarked that 500 or 600 patients are annually admitted to asylums in this country virtually without a history.

Dr. JAMES TAYLOR briefly referred to the possible connection of certain mental failure in epileptics with the administration of some drugs, and especially bromide of potassium,

and he thought this was prevented in some degree by combining strychnine.

The PRESIDENT briefly touched on the mental states in epileptics as recognised in asylums.

Dr. NICOLSON said that the usual form of epileptic insanity was mania with confusion, and emotion, and occasionally melancholia.

Dr. GOWERS briefly replied.

At the close of the discussion the Section passed a resolution appointing a small committee to deal with the subject, the proposals to be submitted to the Council of the Association.

A COMPARISON BETWEEN THE BREAKING STRAIN OF THE RIBS OF THE SANE AND INSANE.

By ALFRED W. CAMPBELL, M.D.,
Pathologist, Rainhill Asylum, Lancashire.

THIS paper forms a sequel to one entitled "The Breaking Strain of the Ribs of the Insane," read at a meeting of the Medico-Psychological Association in London on November 16th, 1894, and published in the *Journal of Mental Science* for April, 1895. In the former investigation the breaking strain of the eighth pair of ribs of 58 unselected patients dying in the Rainhill Asylum was tested with an instrument specially devised by Dr. Mercier, and a microscopic examination of portions of the tested ribs was effected. In the former investigation the eighth ribs of 50 sane persons dying in the Royal Southern Hospital¹ have been tested and examined on precisely similar lines, and the following is an epitomised comparison of the results obtained from the two researches.

The difference between the average breaking strain of the ribs of the insane and that of the ribs of persons free from mental disease is not so great as one would anticipate. There is a preponderance on the side of the latter, but the excess is not a great one. Thus the average breaking strain of the ribs of the 58 insane patients was, for the males, 41.04 lbs. against the convexity, and 42.14 against the concavity; and for the females, 20.68 lbs. against the convexity, and 20.30 against the concavity; while the 50 cases from the Royal Southern Hospital yield an average breaking strain of 42.73 lbs. against the convexity and 42.63 against the concavity for the males; and 23 lbs. against the convexity, and 23.3 against the concavity for the females.

Since in hospital cases one is enabled to practically eliminate the effect of mental deterioration as an agent in the causation of osseous fragility, the effect of bodily disease *per se* in the production of bone weakness can be more accurately studied. This point, therefore, I have specially gone into, and find that the average breaking strain of the ribs of those cases who died of some chronic and at the same time wasting disease is lower by about 6 lbs. than that of cases dying of some chronic but not wasting affection, and again that the average breaking strain of the ribs of cases coming in the latter category is lower by about 6 lbs. than that of cases succumbing to acute diseases or meeting their death by accident. My figures, therefore, tend to show that the influence of chronic wasting diseases in the production of weakness of the bone is probably equivalent to if not greater than that of mental deterioration. In general paralysis of the insane we have a disease in which we may unequivocally state that the mental and nervous degeneration act powerfully in producing bone degeneration. Though this disease generally terminates at an age when the ribs should be at their maximum strength, still their breaking strain is some 20 lbs. below the normal standard.

In both sane and insane there are certain cases—the number is a small one—in which the breaking strain of the ribs is exceedingly low indeed. In these ribs not only are pronounced architectural defects present, but also their density and elasticity are so much diminished that they can be readily sliced through with a knife, and also bend without snapping. In short, a reversion to the osseous condition which obtains in childhood appears to occur. I believe the

¹ I am deeply indebted to Dr. F. H. Barendt, Pathologist to the Royal Southern Hospital, for supplying me with material for this investigation.

change to be a chemical one, but its exact nature and the cause of the increased fragility in these cases remains problematical. The ribs of two women from the Royal Southern Hospital furnish excellent examples of this condition; one aged 60 died of senile decay, the other, aged 53, succumbed to malignant disease of the uterus, and both yielded the extraordinary low breaking strain of 5 lbs. (so far as I have gone in my experiments a record for frangible ribs). The ribs of a man from the same hospital, aged 53, with aortic disease as the certified cause of death, were similar; they had a breaking strain of 18 lbs. against the convexity and 22 lbs. against the concavity, and the case compares well with No. 57 of the table in my previous paper, a man aged 53, whose ribs only required a strain of 20 lbs. against the convexity and 15 lbs. against the concavity to break them, and who a few days before death fractured eight of his ribs by simply falling on his side.

In the same as well as in those mentally afflicted the influence of sex, age, and stature bear an important relation to the breaking strain. This is to say (1) the male rib possesses, roughly speaking, double the strength of the female; (2) after the age of 35 the fragility of the ribs in both sexes increases progressively with the advance of years, and senescence is likewise accompanied by a metamorphosis of the red marrow of the rib into fat; (3) the breaking strain is more or less proportional to the skeletal and muscular development of the individual.

Microscopic examination discloses architectural deficiencies in all those ribs which break at a low strain. These are alteration in the shape of the rib, mainly flattening; a diminution in the thickness or density of the investing rim of compact bone; an absorption of or a simplification of the arrangement of the cancellous trabeculae.

THE RELATION OF DIABETES TO INSANITY.

By C. HUBERT BOND, M.B., C.M.,

Pathologist and Assistant Medical Officer, London County Asylum, Harefield.

Dr. BOND read a paper on this subject, in the course of which he said that, taking the total number of cases in our asylums, sugar in the urine of the insane is not of frequent occurrence, but when limited to recent cases a larger proportion is found. In the following cases all known fallacies have been eliminated, and the corroborative fermentation test used. In the urine of 175 cases examined within forty-eight hours of admission, sugar was found in 12—that is, 6.85 per cent. The following table shows the distribution of these cases:

Form of Mental Disorder.	Total Number of Cases.	Instances of Glycosuria on Admission.
Epileptic Insanity ...	18	—
General paralysis ...	30	2
Mania ...	43	—
Melancholia ...	55	6
Intermittent Insanity ...	5	—
Organic dementia ...	6	2
Senile Insanity ...	14	1
Constitutional cases ...	2	—
	173	12

In these 12 cases most of them show an absence of many of the chief signs of diabetes. The temperatures of the patients was almost invariably subnormal. In 2 melancholias who recovered the improvement in their mental condition was coincident with the gradual disappearance of glycosuria. The frequency of a previous history of alcoholic excess is notable.

VOLUNTARY BOARDERS IN ASYLUMS.

By PRACY SMITH, M.D., F.R.C.P.,

Medical Superintendent, Bethlem Royal Hospital.

Dr. PRACY SMITH read a paper on the above subject, in which he said that the practice of admitting patients as voluntary boarders without certificates had grown largely of

late years.¹ He then gave the following examples of patients who had applied for admission as voluntary boarders into Bethlem Hospital:

1. Recurrent cases, where the patient is conscious of a return of the malady.
2. Mild cases of melancholia, perhaps with suicidal feelings, for which the patient—often in this matter wiser than his relatives—desires to be under care.
3. Occasionally patients with homicidal feelings.
4. A patient who had had a series of epileptic fits and was conscious of the onset of maniacal excitement.
5. Some early cases of general paralysis where the physical signs largely precede the mental.
6. Some cases of partial weak-mindedness.
7. Cases of morphinism, cocaineism, alcoholism; in the latter condition some patients prefer to go voluntarily to an asylum rather than to a retreat under the Inebriate Act.
8. Patients suffering from hallucinations which they recognise as such.
9. In one case a certifiable patient insisted on coming in voluntarily during the delay his friends experienced in getting a justice to make a reception order.
10. Cases in whom no marked symptoms of insanity have been observed after admission or whose reception order cannot be renewed, but who wish to remain for convalescence to be established. One certified patient with a very complete remission remained as a voluntary boarder for three years, till it was necessary to recertify him.
11. In some patients especially, medical men and nurses, it seems desirable for their future to avoid certification, and admit them voluntarily if they understand what they are doing.

Certain difficulties are met with—patients are sometimes sent up by medical men for admission who are quite unfit to be admitted without certificates. The writer always adopts the practice of asking the patient if he understands the nature of the hospital, as it seems quite indefensible to disguise this fact till after admission, and it is equally wrong to admit as voluntary boarders those who have lost their will power and will consent to anything. Every voluntary boarder admitted to Bethlem Hospital signs an agreement to conform to the rules and his friends sign an agreement to remove him or take other steps for his care when notice is given.

It is possible patients may simulate the milder varieties of insanity. To obviate this the history should be as carefully taken and the notes as carefully kept as is done with certified patients. At present there is no arrangement for the possible admission of voluntary boarders of the poorer class to county asylums, and it is worth considering whether some provision of this nature is not desirable.

Dr. JAMES STEWART (Olifton) said the alcoholic prefers to go to an institution like Bethlem as a voluntary boarder because he is free to leave without let or hindrance when he pleases. During an experience of eighteen years in the treatment of inebriates he has observed that the greatest obstacle to the permanent cure of such cases is the difficulty of persuading them that general health may be apparently perfectly restored and yet the physical condition of the brain be such that the will-power cannot be exercised effectually when exposed to temptation when protection from king alcohol is removed.

Dr. BONVILLE FOX said there was one class Dr. Smith had not mentioned, namely, that a friend or relative might be admitted as a voluntary boarder for the sake of companionship to a patient.

Dr. PRACY SMITH briefly replied and pointed out that at Bethlem Hospital they did not admit friends or relations unless themselves suffering mentally.

¹ It is now legal for any person who is desirous of voluntarily submitting to treatment to be admitted into asylums and hospitals for the insane, under certain restrictions, the most important being the previous consent of Commissioners in Lunacy in the case of a patient who desires to go to a private asylum. The Commissioners dislike to give consent for the voluntary admission of a patient who, though retaining his illness and desiring to be under care, may yet be certifiable, but the reading of the Act does not seem to require such a rigid reading.

THE LAW IN RELATION TO SINGLE PATIENTS.

By LIONEL A. WEATHERLY, M.D.,
Bath.

DR. WEATHERLY read a paper on this subject, in which he said that not only is the system of placing single cases of insanity in private houses without certification and its consequent supervision becoming more and more general, but we have now constantly brought before our notice unlicensed houses in which several persons of unsound mind are boarded in direct violation of the law; and to such a pass has failure of the prosecution in these cases arrived, that he believed it is an open secret that "the authorities that be" have given out that they do not intend to bother themselves any more about such defiance of the law. He then put forward three suggestions:

1. Educate your public to recognise that insanity is no crime but a disease; that it is nothing to be ashamed of, and that the certification of insanity does not in any way mean publicity.
2. In those cases in which certification may be difficult, that it should be insisted upon that a report should be sent to the authorities stating that So-and-so has been placed in a certain house for care and treatment, but that the unsoundness of mind is not sufficient to admit of certificates being signed.
3. To admit of proper supervision of all these cases that district officials be appointed to act, as it were, as subcommissioners.

DR. HAYES NEWINGTON remarked that the chief difficulty in enforcing the law in this matter was, as in other matters, in the extraordinary view that judges took of law. The law was plain enough, but a question had of late been left to the jury, which seemed to be quite outside the law. This question was, Did So-and-so receive a patient for treatment in the same manner as patients are received in asylums? It was much to be regretted that where such a point had been left, the question was not at once asked, What is the difference between the treatment in a private house of a certain case and that which the same individual would have received in an asylum?

DR. HYSLOP said that before a medical man or other person was allowed by the Commissioners to receive more than one patient into an unlicensed house, it was necessary to prove that the one would benefit the other, which was generally very difficult to prove.

DR. DOUGLAS said he thought that rule was made so that, for instance, a sister might be received as a companion to her insane sister, but he thought that this point was often stretched. He agreed with Dr. Weatherly that nothing could be done without educating the public.

DR. WEATHERLY briefly replied, and said that he could not agree with Dr. Douglas that the Commissioners often stretched the point, as he considered them much against private patients.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, ETC.

CASES OF POISONING BY LABURNUM SEEDS.

CASES of laburnum poisoning are apparently not of common occurrence, and the following cases which recently came under my notice may perhaps be of interest as showing its poisonous properties.

On Saturday, August 10th, I was sent for hurriedly to see three children who had been suddenly taken ill.

On arrival I found the eldest, a boy of 11 years of age, very much collapsed, deathly pale, cyanosed, and vomiting. The pupils were dilated and equal, pulse quick and feeble, and the skin cold.

On making inquiries, I found that he and his brothers had been during the morning at a pleasure park about a mile away, and had had eaten what they believed to be tares, and of which they had brought some home. On examination I

found them to be the pods and seeds of the common laburnum (*Cytisus laburnum*).

I promptly administered an emetic (zinc sulphate, grs. xx), producing free vomiting, following it up with copious draughts of warm water, which was soon returned, bringing with it a large number of laburnum seeds.

He was then placed in bed with hot bottles to his feet, and, on account of his collapsed condition, I gave him several doses at short intervals of chloric ether and salvolatile followed by the administration of strong hot coffee.

Under this treatment he speedily rallied. When I saw him again several hours later his pulse was quieter and stronger and his general condition considerably improved although slight sickness continued for several hours afterwards. Slight diarrhoea supervened some twelve hours later.

He has since told me that mistaking the laburnum for tares he ate the seeds of some 18 or 20 of them, and about an hour later whilst returning home he felt sick and giddy, his head ached, and he could scarcely see, in fact he felt so weak and ill he could hardly walk home. On arriving home he was very sick and was in the condition above described when I first saw him.

The other two children, ages nine and six years, both presented similar symptoms, though in a less degree, and speedily recovered after the administration of emetics; though very exhausted for a short time, and complaining of feeling very sleepy. On visiting them the following day they had all fully recovered and in fact seemed none the worse for the previous day's experience.

The chief points of interest appear to be:

1. That laburnum is an active poison capable of producing, even when taken in small quantities, severe symptoms of depression.
2. That its action is not merely irritant, but producing when absorbed into the system narcotic symptoms, thereby entitling it to be placed in the class of narcotic irritants.
3. Entire absence of the symptoms, foaming at mouth, pain in abdomen, and convulsions.
4. The rapid subsidence of the symptoms on removal of poison and the administration of diffusible stimulants.

HABLEY TOMLINSON, M.R.C.S.Eng., L.R.C.P.Lond.

Gateshead-on-Tyne.

Two children, aged respectively 4 years and 20 months, were found in possession of laburnum pods about 4 p.m., but they said they had eaten none of them.

Two hours and a-half later I was called. They had asked for food about 5 o'clock, and begun to eat when the older one turned sick and got up and tried to walk, when he remarked, "I can't stand: I'm drunk." They both vomited then, and the vomit contained laburnum pods.

When I saw them at 6.30 I found the older one lying down, not caring to be roused. He seemed inclined to sleep. The pulse was slow and the beat weak but not irregular. The younger one could be more easily roused.

I gave both a full dose of zinc sulphate with emesis as the immediate result. They both vomited chewed laburnum pods mixed with food. In five minutes I gave them more zinc sulphate, and again they vomited, but there were no pods this time in either. They seemed to have got rid of most of the pods before I saw them, and to be suffering from the active principle which had been absorbed.

They complained of no pain in the bowels, and there had been no purging. The older one was now pale, and in a very depressed state, and I injected 5 minims of ether. This I repeated every thirty minutes, sometimes oftener, being guided by the pulse. Between these doses they had both whiskey and hot coffee.

They were kept up in this way for three hours, when I was joined by a consultant; and I then got tannic acid and gave each 5 grains, with the object of reducing the active principle to an inactive state. By this time the heart of the older one was again flagging, and we douched the chests of both alternately with hot and cold water. This improved the pulse very much, and this improvement being kept up, we felt that by 10.30 p.m. they could be with safety allowed to sleep, especially as I was within easy call.

Twelve hours later they were almost as bright as ever, and crying for solid food.

J. G. McNAUGHTON, M.B., C.M. Edin.

CASE OF DIPHTHERIA TREATED BY ANTITOXIN.

A. R., a boy, aged 4 years 3 months, was first seen on August 19th, 1896. The child had been ailing for a fortnight previously, but began to get worse on August 15th, with cough and croupous breathing. He suddenly got worse on the night of the 18th. I was called in on the 19th. On examination I found both tonsils enlarged, the right being covered with a dirty-looking yellow membrane; the uvula was elongated, and the throat generally congested. On the evening of August 19th the temperature was 99.8°, pulse 144, breathing rapid and stridulous, urine loaded with albumen. The throat was painted with tr. ferri perchlor.

On August 20th, temperature 98°, pulse 140, throat just the same. The child had had a very restless night. Breathing stridulous and quick. Six c.cm. of antitoxin serum were injected between the scapulae, the skin being previously rendered aseptic by turpentine and carbolic, and a carbolic pad placed over the puncture. At 1 P.M. the pulse was 132, the temperature 98.4°, patient very restless, breathing rapid and stridulous. At 9 P.M. temperature 98.4°, pulse 120, the breathing was much quieter, and the patient had slept most of the afternoon.

On August 21st, at 10 A.M., temperature 99°, pulse 132; 5 c.cm. of serum were injected about the same place as before. The patient looked much brighter and the breathing was quieter. The membrane on the right tonsil looked smaller and thinner; there was a small patch on the left tonsil. On August 22nd, at 10.30 A.M., temperature 98.4°, pulse 130. The boy had had a good night; breathing was much more regular and easy; the cough had almost disappeared; the membrane had nearly gone from the right tonsil, but there still remained the small patch on the left one; the throat generally was slightly congested. The child was much brighter and had taken some nourishment (milk and soft biscuit). Albumen was still present in the urine, but much less in quantity. On August 24th the child had had a good night; breathing was regular and almost normal; temperature 98.4°, pulse 98; the throat was quite clear, and there was no congestion. The patient continued to improve, taking food, sleeping, and breathing normally. The urine was free from albumen on August 26th, and on the 28th the patient was quite well.

Holbeck.

J. W. H. BROWN.

BLUEBOTTLE LARVÆ IN THE EAR.

On August 16th a patient came to this hospital at 10 P.M. complaining of bleeding from the left ear, which came on directly after a fall from a horse the same afternoon. When seen, the man had a blood-stained discharge from the left ear, said he had noises in his head, and complained of giddiness and deafness. On examining the meatus by reflected light, I saw several white bodies moving about in front of the tympanic membrane, and, on extracting one with forceps, found it to be a full-grown gentile (the larva of the bluebottle fly); I then removed five others of the same size and syringed out the ear. On again examining the meatus, the membrane was seen to be quite intact, but of an opaque white colour; there was an ulcerated surface on the posterior wall of the canal immediately external to the membrane. I saw the patient on the following morning, when all his ear symptoms had disappeared.

On being questioned, he owned to having suffered for some time with deafness and noises in the head on the left side, but he noticed no discharge till his fall on the head that afternoon.

The case is interesting on account of the unusual situation for the deposit of the fly's eggs; the little discomfort occasioned by the presence of six lively gentiles in the meatus; and lastly, the sudden bloody discharge after a fall on the head, accompanied by giddiness and deafness, which made one at first suspect a fracture of the base of the skull.

H. L. E. WILKS,
House-surgeon.

Salisbury General Infirmary.

CASTRATION IN ENLARGED PROSTATE.

H. H., aged 82, an old Hungarian, had suffered for some years from retention of urine and cystitis, necessitating the almost incessant use of catheters. For six years past he had

been unable to leave his cottage, and when admitted to hospital was in a miserable condition, getting no rest night or day from the pain and distress caused by the continual desire to micturate, the bladder being intolerant of urine about every quarter of an hour. The urine was in a stinking condition, viscid andropy. Rectal examination showed an immensely enlarged prostate, the finger being not long enough to reach its boundaries. On April 18th, after a preliminary hypodermic injection of a quarter of a grain of morphia, the operation was performed under chloroform, as described in the BRITISH MEDICAL JOURNAL of January 5th, the testicles being removed through a median incision of the lower part of the scrotum. Immediate relief was obtained, the patient retaining his urine four hours, and passing it free of pain.

One or two attacks of cystitis recurred requiring irrigation of the bladder occasionally, and convalescence was retarded by an acute attack of hysterix. He was discharged early in July quite free of all his troubles, having gained rapidly in weight and strength, and, according to his own statement, as well as he was thirty years ago. He can now walk three or four miles, and only complains of being always hungry.

Before his discharge examination per rectum showed that though the prostate had diminished considerably in size it had by no means disappeared, as described in some previous cases.

Superintendent, Hokitika Hospital, N.Z.

REPORTS

ON

MEDICAL & SURGICAL PRACTICE IN THE HOSPITALS
AND ASYLUMS OF GREAT BRITAIN, IRELAND,
AND THE COLONIES.

ROYAL NAVAL SICK QUARTERS, YOKOHAMA.

ABDOMINAL ABSCESS: LAPAROTOMY: RECOVERY.

(By Staff-Surgeon H. J. McC. TODD, R.N.)

[Communicated by the DIRECTOR-GENERAL OF THE MEDICAL
DEPARTMENT, R.N.]

J. F., aged 19, was admitted into hospital on February 21st, suffering from sores on the prepuce, and an abscess over the left sacro-iliac synchondrosis, which was opened next day. The patient was confined to his bed. On February 23rd, at 7 P.M., he experienced very severe pain in the right iliac region, rendering respiration difficult. The temperature was 98°; the bowels were open. He was ordered a hypodermic injection of morphia and fomentations, and a milk diet. On February 26th the bowels were confined, and an enema was administered, followed by a natural motion. There was no nausea, but great tenderness and persistent pain, aggravated by the slightest movement, in the right iliac region. The respiration was thoracic. There was a slight increase of dullness in the iliac region and hectic pyrexia. On February 28th the bowels had only acted after an enema; the motion contained clear mucus, and was followed by much pain in the lower half of the abdomen. There was dullness and extreme tenderness in the right iliac region, and the hectic fever persisted. On March 1st a diffusive tender swelling in the right iliac region was made out. On March 3rd a formed stool was passed after an enema. There was some tenesmus, and mucus was passed later. The iliac swelling was more pronounced, and on March 5th it had attained about the size of a cocoa-nut, and occupied the entire right iliac region. Its margins were fairly defined; there was no superficial redness or oedema.

At 10 A.M., assisted by Staff-Surgeon Barnes and Dr. Munro, the region having been previously shaved and rendered aseptic, chloroform was administered, and I made an incision over the most prominent part of the swelling 2 inches internal to the right anterior superior iliac spine and parallel to Poupart's ligament. After division of the abdominal muscles, an exploring needle was thrust into the swelling and pus withdrawn. The opening was now enlarged with a probe pointed bistoury, and half a pint of thick rather foetid pus escaped; on introducing my finger into the abdominal cavity, the intestines within reach were found to be

matted together by soft adhesions which readily broke down, and allowed of a further escape of pus; the appendix was not found to be altered; the wound was gently irrigated with hot boric lotion, and a large drainage tube inserted; the patient was propped up so as to lie on his right side, a dressing of lint soaked in boric lotion, and marine tow was applied. On recovering from the anæsthetic, the patient expressed himself as greatly relieved.

The subsequent course of the case was almost uninterrupted; the temperature the evening of the day of operation was 99°. There was retention of urine for two days, necessitating the use of a catheter. The bowels acted naturally two days after the operation, and the drainage tube was removed on the third day. On March 20th, the wound being now soundly healed, the man was allowed up, wearing a pad and bandage. On April 10th the wound was quite sound; there was no protrusion of the cicatrix on coughing.

I may mention that there was no history of injury or previous abdominal trouble.

THE INFIRMARY, MACCLESFIELD.

THE DANGERS OF COCAINE.

(By J. H. MARSH, M.R.C.S., L.R.C.P., Senior House-Surgeon.)

THE advantages of cocaine as a local anæsthetic are so generally admitted that there seems to be a danger lest the risks attendant on its use in certain individuals should be overlooked. I have recently on three separate occasions had these dangers brought forcibly under my notice whilst using cocaine as a local anæsthetic preparatory to dilating strictures of the urethra with Lister's sounds.

Twenty minims of a 10 per cent. solution of hydrochlorate of cocaine, freshly prepared and free from turbidity, were injected with a small glass syringe down the urethra, care being taken not to injure the mucous membrane. In all three cases within five minutes of the application alarming symptoms of collapse manifested themselves. The patients first complained of dimness of sight, became intensely pale, the pupils dilated, the forehead was covered with cold clammy perspiration, the respiration was gasping, and the pulse quickened. Twenty minims of ether were injected hypodermically, hot bottles were applied, and as soon as the patients could swallow diffusible stimulants were freely administered. In two of the cases nitrite of amyl in 3 minim capsules was used in addition, and recovery in consequence was much more speedy.

These three cases are, I think, interesting as showing how in certain individuals toxic symptoms arise from the absorption of a very small quantity of cocaine by unbroken mucous membrane.

REVIEWS.

LA FIÈVRE TYPHOÏDE [Enteric Fever]. Par MM. BROUARDEL et THOINER. Paris: Baillière et Fils. 1895. (Imp. 8vo, with 24 Figures, pp. 400. 9 francs.)

THIS very complete work on enteric fever answers well to the modern notions of what a full study of an infection should be. It differs mainly from the descriptions hitherto usually given by its elaborate account of the etiology of the disease as caused by Eberth's bacillus, by a section on general pathogeny, and by one on prophylaxis. The history of the disease is summarised in a few words, and the older theories of its mode of origin are shortly dealt with. In Section 3 there is an admirable and almost exhaustive account of the morbid anatomy of the organs involved, followed in each case by a description of the symptoms arising from such lesions.

The next section gives shape and completeness to the preceding one by its description of the various clinical types of the disease, including the mode of termination, complications, and sequelæ.

Section 5, on general pathogeny, includes an account of experimental typhoid fever, and a pathogenic analysis of the principal localisations of the disease: this is followed by

what is aptly termed a "pathogenic synthesis" of the whole morbid anatomy, including bacteriology.

The following sections deal satisfactorily with diagnosis, prognosis, and treatment. The last named is fully discussed. Very little space is given to the antiseptic treatment, but it is held that the mortality has been reduced by the cold bath treatment.

The section on prophylaxis includes that of the individual and of communities, whether aggregated together in towns, or in more compact masses in barracks, etc.

This work is based upon an extensive acquaintance with the disease, and a thorough knowledge of the writings of workers in this field, such as Murchison in this country, Louis in France, and Griesinger in Germany. It may confidently be recommended as containing an excellent account of enteric fever.

THE CAMBRIDGE NATURAL HISTORY. Volume III, comprising "Molluscs," by the Rev. A. H. COOKE, M.A., Fellow and Tutor of King's College, Cambridge; "Brachiopods (Recent)," by A. E. SHEPLEY, M.A., Fellow of Christ's College, Cambridge; and "Brachiopods (Fossil)," by F. R. C. REED, M.A., Trinity College, Cambridge. London: Macmillan and Co., 1895. (Demy 8vo, pp. 551. 17s.)

THIS volume is the first instalment of a series which is to consist of ten volumes, each of about 500 pages complete in itself. It treats of the natural history of molluscs and brachiopods. We are glad to be able to welcome this first instalment, and the more so as the great expectations we have been led to form have in this volume at least been realised. The series has many distinctive characters. It is intended, in the first place, for such persons as have not had any special scientific training and who are not necessarily acquainted with scientific language. At the same time it combines popular treatment with the latest results of modern scientific research, so as to make the work useful to those who may be regarded as serious students of the various branches of which it treats. From this latter point of view the work may be considered as a scientific treatise on one aspect of zoology, and an aspect, moreover, that has not received that share of attention of late years that its importance deserves—modern zoological work dealing largely with laboratory, as opposed to field research. One of its most interesting features is the amount of space devoted to the various animal groups. In most works with a similar purpose the vertebrates receive by far the larger share of attention; and yet they are but one group, equal only in morphological interest to one of the subdivisions of that vast heterogeneity of forms loosely termed invertebrates. In this work the individual groups are allotted space in the order of their importance—a decided advance on previous treatises. Within the short limits of a brief notice it is impossible to do justice to a work of such importance. We can only point out that it is the product of the united labours of the leading men of a great zoological school, and as such must take a high place among the vast number of works attempting to deal with the same subject.

THE PRACTICE OF MASSAGE: ITS PHYSIOLOGICAL EFFECTS AND THERAPEUTIC USES. By A. SYMONS ECCLES, M.B. Aberd. London: Macmillan and Co. 1895. (377 pages; 7s. 6d. net.)

THE general arrangement of this work is on familiar and strictly orthodox lines. The author commences with a description of the various manipulations, and relates with commendable care and minuteness the methods usually adopted in applying massage to different parts of the body. The customary chapter is devoted to an account of the physiological effects of massage as far as they are known, and then follow in due course the usual articles on diseases of the joints, the disorders of digestion, the affections of the nervous system, and so on. We gather from statements made in the preface and elsewhere throughout the book that Dr. ECCLES is himself a practical masseur, and that he has the requisite skill and knowledge to carry out his own prescrip-

tions. This is the plan almost universally adopted on the Continent, and it has many advantages, although its general adoption by busy practitioners with other demands on their time and energies would present insuperable difficulties. To thoroughly massage even half a dozen patients in the course of the day would be a severe strain on the physical strength of the operator, especially as we are told that from three quarters of an hour to one hour and a quarter is the time usually required to thoroughly manipulate every part of the body in general corporeal massage, and that even this will not suffice if vibrations and active movements are to be included. The author states that in his experience remarkably different results are obtained in the same case when massage is administered by an expert, well instructed conscientious rubber at one time, and by the physician conducting the case in another. "Both equally endowed with mechanical dexterity, the one tries to carry out intelligently his instructions while the other does himself what he knows to be required."

One of the best articles in the book is that devoted to the value of massage in the treatment of skin diseases—a subject which, according to the author, has received very inadequate attention at the hands of the dermatologists. He complains that in a recent work on skin affections the subject is dismissed in five lines, two of which are devoted to the statement that "it has been quacked as usual, having been put forward as a preventive of wrinkles of the face." Dr. Eccles points out that the obliteration of wrinkles has been observed, not as the result of facial massage, "but following on the redeposition of fat and the better nutrition of the skin after a course of general massage in many cases of malnutrition in which the skin of the face has participated in the general aggrandisement of the tissues."

A fairly exhaustive account is given of the value of massage in fractures, a method of treatment originally advocated by Lucas-Championnière in 1886. In connection with the subject reference might have been made to the cases recorded by Dr. Arvid Kellgren in his well-known *Technic of Ling's System of Manual Treatment*, a work which seems to have escaped the author's notice.

A useful feature of the book is the painstaking care with which the various references to papers and works dealing with different branches of the subject have been worked up, the titles of many of them being given in an appendix. Dr. Eccles, perhaps wisely, avoids all reference to what may be called the ethical side of the question, and to the existence of the immoral massage establishments which occupied recently a good deal of attention.

ORGANIC CHEMISTRY. By W. H. PERKIN, jun., Ph.D., F.R.C.S.; and F. STANLEY KIPPING, Ph.D., D.Sc. London: W. and R. Chambers. (Part I, 1894, pp. 302. 3s. 6d. Part II, 1895, pp. 257. 3s. 6d.)

This elementary textbook of organic chemistry is a distinct departure from the ordinary type. Both authors are well known original workers in their subject, and hence not only is the work thoroughly up to date, but the practical way in which the facts are represented, accompanied by such a laboratory course as is here indicated, cannot fail to give the student a real insight into organic chemistry. Even the student who is so unfortunate as not to have access to a laboratory cannot fail to see by what laborious work the science is built up.

Considering the importance of the physical side of organic chemistry, however, it is disappointing to find so little attention given to it here. Even such physical methods as are required for molecular weight determination might have been revised with advantage. Thus, in the example of the cryoscopic method worked out, we are told that 4.9818 grammes of cane sugar dissolved in 96.94 grammes of water caused a depression in the freezing point of 0.296. Seeing that here the magnitude to be measured cannot be known to be nearer than, at the best, 1 part in 300 (0.001 being the outside limit of the temperature measurement), it might surely have been indicated that to carry the weighings of the sugar beyond the second place, and of the water beyond the first place of decimals is pure waste of time. Taken as a whole, however, the work is undoubtedly one of the best elementary textbooks on organic chemistry written in this country.

THE USE OF SHORTHAND BY THE PRACTITIONER, WITH EX-AMPLERS. Issued by the Society of Medical Phonographers, and sold by Sir J. Pitman and Sons, 1, Amen Corner, E.C. (Fcap. octavo, pp. 31. 8d.)

This forms the sequel to the *Use of Shorthand by the Student*, already noticed in these pages. The writer affirms that, compared with longhand, shorthand enables a given amount of record to be made in one-third the time and with less than one-third the trouble, whilst at the same time it promotes accurate observation and exercises upon the practitioner's work an educational influence of the highest value. The different methods of keeping the notes taken, based upon the experience of the writer and other medical phonographers, are given, and suggestions made for the preservation of isolated observations and the record of facts met with in reading. The best forms of notebook, and the best pens, ink, and paper are mentioned, but, most important of all, how to index the accumulating mass of notes, so that any of them is available for immediate reference, is clearly described. Practitioners who keep notes of their cases will find this publication very helpful.

REPORT ON YAWS IN TOBAGO, GRENADA, ST. VINCENT, ST. LUCIA, AND THE LEEWARD ISLANDS; addressed to the Right Honourable Lord Knutsford, G.C.M.G., Her Majesty's Principal Secretary of State for the Colonies. By H. A. ALFORD NICHOLLS, M.D., F.L.S. London: Her Majesty's Stationary Office. 1894.

In his admirable report Dr. Nicholls points out that yaws, originally introduced by West African negroes, after being kept in check in the olden times by the slave owners, has increased and spread since emancipation permitted the negro gradually to revert to a state of semi-savagery; so that now this loathsome disease has become a veritable pest in many parts of our West Indian colonies. Many laws have been enacted with a view to its limitation and ultimate suppression, but, from the squalor, ignorance, and superstition of the people, from indifference on the part of the executive, and because in many instances they proved to be of an unworkable character, these laws have become practically a dead letter, and, in spite of them, in nearly every one of the islands the disease is gaining ground. All this Dr. Nicholls points out in great detail; at the same time he indicates methods of a practical nature by which this spread might be effectually checked and the disease itself in time exterminated.

Besides fully discussing these matters the report contains much valuable clinical material, and also a very carefully prepared systematic description of the symptoms, course, histology, bacteriology, and treatment of yaws. Dr. Nicholls points out very clearly and convincingly that the view that yaws is but a form of syphilis—a view which, in his preface to Mr. Numa Rat's well-known memoir, Mr. Jonathan Hutchinson seems to favour—is absolutely erroneous. He shows that yaws is a disease *sui generis*, quite distinct and in no way connected with syphilis, unless in certain cases by accidental concurrence. In this view he is supported by most of those recent writers who have themselves enjoyed a practical acquaintance with the subject. Correct views on this point are not only of theoretical interest; they have a very practical and manifest bearing on treatment and prophylaxis.

Dr. Nicholls does not favour the now generally accepted opinion that yaws and the parangi disease of Ceylon are identical. He has similar doubts about the coko disease of the Fiji Islands; in fact, he seems to think that hitherto yaws was confined to Africa and America. In this we submit that he is wrong, for not only are Kynsey's and Macgregor's descriptions fairly decisive on the point, but recent testimony—such as that supplied by Surgeon-Captain F. Smith for North Borneo and Mr. Arthur Powell for Assam—distinctly proves the existence of yaws in these countries, and if in these countries why not in other parts of Asia and Polynesia?

Dr. Nicholls has found a micrococcus in the characteristic

fungating skin granulomata of the disease as well as in the peripheral parts of certain of the viscera. This micrococcus he has succeeded in cultivating, but his attempts to inoculate the lower animals with his cultures proved a failure.

Not the least valuable part of this report is the appendix, in which will be found many excellent microscopic drawings illustrating the histology of yaws. Besides these there are some fairly executed chromo-lithographs of the eruption which cannot fail to prove acceptable to dermatologists.

We notice allusions in the body of the report, under the names "Coolie itch" and "dermatitis orientalis," to a disease about which we should like to have a little more information. He speaks also of a form of endemic lupus common in certain parts of Dominica. What are these diseases?

Dr. Nicholls would confer a great boon on all interested in dermatological and tropical matters if he would condense and systematise the great mass of valuable material he has so laboriously accumulated. In its present shape, however useful it may prove for official purposes, it is practically lost to the reader who may wish to get at the principal facts without the labour and waste of time necessary for their extraction from these 300 and odd closely printed pages.

AUTOBIOGRAPHY, JAMES BEART SIMONDS. London: Adlard and Son. 1894. (Demy 8vo, pp. 92.)

Though written in a somewhat prosy style, not uncommon to a generation whose living representatives are very few, this little reprint from the *Veterinarian* contains much that cannot fail to be of special interest to the veterinary profession with which its author has been so long and so honourably connected. The detailed narration of a long association with the diseases of the domestic animals offers attraction to the student of comparative medicine.

Qualifying as a veterinary surgeon in 1829, when the Examining Board of the Royal Veterinary College included Sir Astley Cooper, Sir E. Home, Sir B. Brodie, Abernethy, Joseph Henry Green, Charles Bell, Rabbington, and Coleman, Mr. SIMONDS spent the few succeeding years in provincial practice. In 1842 he was called to the Chair of Cattle Pathology at the Royal Veterinary College, a position which he held for half a century, during the last decade of which he was also Principal. In addition to his duties in connection with the College, Professor Simonds was intimately associated with the Royal Agricultural Society, of which he was an original member, and with the Veterinary Department of the Privy Council as its first professional adviser, also with the *Veterinarian* as its editor. This autobiography, which gives many details of the writer's work in connection with the several departments named, is a valuable addition to the history of the veterinary medicine in this country, and tells more authoritatively of the incursion of exotic cattle diseases, and the means adopted to prevent and eradicate them, than could be told, as the result of personal experience, by anyone else. The manner of narration may possibly be tedious. The speculative genealogy of the Simonds's family, which occupies the first few pages, fail to interest any except the biographer, but to those who desire information on the history of contagious diseases of animals in Great Britain and the inception of the State Department which deals with them, this pamphlet will be acceptable.

NOTES ON BOOKS.

A Textbook of Organic Chemistry. By A. BERNTHSEN, Ph.D. Translated by G. M'GOWAN, Ph.D. Second Edition. (London: Blackie and Son, Limited, 1894, pp. 396. 7s. 6d.)—This is a translation from a well-known German textbook of the ordinary type. After a short introduction on the methods of determining the constitution and physical properties of organic compounds, the subject is developed upon orthodox lines, beginning with the hydrocarbons; these being completely dealt with before considering the haloid compounds and alcohols, and so on. It is doubtful, however, whether this plan is the most suitable for beginners, the alternative method of starting with a few well-known organic substances and deriving from these examples of all the chief types of compounds is probably preferable with elementary

students. The present work will be chiefly valuable as a handy reference book for students past the rudiments of the subject. The introductory chapters on Constitution, Isomerism, and Physical Properties of Organic Compounds might be enlarged with advantage.

Climatologie Médicale de la République Argentine et des Principales Villes d'Amérique. [Medical Climatology of the Argentine Republic and of the Principal Towns of America.] Par Dr. SAMUEL GACHÉ. (Buenos Ayres: Imprimerie "Mariano Moreno." 1895. Roy. 8vo, pp. 984.)—This large and imposing volume presents an elaborate and painstaking compilation of such observations as were available to the author on the subject he undertook to treat. It has the merits and the defects of a work conceived and executed on such a plan. It is a monument to the industry of the author, but it is dry and tedious to read, and its accumulation of facts, of no remarkable novelty or interest, is unrelieved by any bright passages of description or any original or interesting discussions. The book also lacks an index, though it is provided with a table of contents, and, strange to say, in a work assuming so pretentious a form, there is not a vestige of a map in the whole 917 pages. There is a vast amount of quotations from works and papers familiar to the European reader which seems somewhat irrelevant to the main subject of the book, as they have no special reference to the climate of the Argentine Republic; while, on the other hand, much information that we should expect to find here is absent.

Therapie der Harnkrankheiten. [Treatment of Urinary Diseases.] Von Professor O. POSNER. (Berlin: A. Hirschwald. 1895. Demy 8vo, pp. 144, with 11 illustrations.) Last year we had occasion to review an excellent small work by Professor Posner on the diagnosis of urinary diseases; this is a companion volume of ten lectures on the treatment of these diseases. The first four lectures are given to the treatment of gonorrhoea, both acute and chronic, including complications. Urethral stricture is dealt with in Lecture V. Under new growths in the urinary passages bladder tumours and enlarged prostate are taken. A short account is given of prostatectomy (McGill's operation), and also of castration, the chief credit in the latter case being attributed to American and Italian surgeons. Under the changes in the chemistry of the urine gravel, phosphaturia, oxaluria, etc., are described. In Lecture VII renal calculus, including colic, are dealt with, as well as vesical calculus. The various operations for stone in the bladder are here given, suprapubic lithotomy, with the after-treatment, receiving special attention. The lecture on functional nervous disease also includes sexual functional disorders in the male. The last lecture deals with infections and intoxications starting from the urinary organs. This book contains a practical and judicious account of the treatment of these various diseases.

On the Relation of Diseases of the Spinal Cord to the Distribution and Lesions of the Spinal Blood Vessels. By R. T. WILLIAMSON, M.D. (London: H. K. Lewis. 1895. Roy. 8vo, pp. 43, 2s.)—In this pamphlet, which has been reprinted from the *Manchester Medical Chronicle*, Dr. Williamson calls attention to the somewhat neglected subject in neurological pathology. He gives an admirable account of the distribution of the blood supply, and affords from his own pathological observations good evidence that in many cases of acute poliomyelitis, of acute myelitis, and syphilitic cord disease; arterial obstruction, either by embolism or thrombosis, is the effective cause. The illustrations are somewhat rough, but sufficient to indicate the author's meaning.

Descriptive Catalogue of the Pathological Specimens in the Museum of Guy's Hospital. 3rd edition. Vol. I. Morbid Conditions of the Respiratory Organs and Alimentary Tract. By LAURISTON C. SHAW, M.D., Assistant Physician and Curator of the Museum, and C. COOPER PERRY, M.A., M.D., Assistant Physician and Demonstrator of Morbid Anatomy. (London: J. and A. Churchill. 1894. Roy. 8vo, pp. 460.)—In issuing this edition of their *Museum Catalogue*, the authors have been guided by the belief that the study of a pathological specimen is made at once more interesting and of greater practical

utility when combined with a study of the history during life of the case from which the preparation has been derived. Hence we find that in nearly all cases there has been appended to the description of the specimen a short clinical history of the case from which the specimen was derived. This is a principle which is at once sound and of great practical utility in its accomplishment. The thanks of all Guy's students are due to Drs. Shaw and Perry, as well as those of the profession at large who may wish to use the museum for research or record.

Short and Easy Book-keeping, a Concise System of Double Entry. (A Handbook for Traders and Students). By S. W. FLINT, Chartered Accountant. (Published by Effingham, Wilson, and Co., Royal Exchange. 6d.)—This little book, which has reached its twenty fifth thousand, contains within the compass of its 44 pages all necessary information for the keeping of accounts in a clear and satisfactory manner. Mr. S. W. Flint's method has the recommendation of extreme simplicity.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

APENTA WATER.

We have received from the Apollinaris Company specimens of the new Hunyadi water which they are about to introduce under the name of "Apenta." Apenta is a natural aperient water drawn from the Uj Hunyadi springs, near Buda-Pesth. It affords those guarantees of uniform strength and composition which have long been wanting in the best known Hunyadi waters. The chemical composition of the water, according to the analysis of Professor L. Liebermann, Director of the Royal Hungarian State Chemical Institute in the Ministry of Agriculture, Buda-Pesth, is as follows:

Sulphate of soda	15.4320
Sulphate of magnesia...	24.4800
Sulphate of lime	1.0282
Chloride of sodium	1.0000
Carbonate of lime	0.8043
Carbonate of protoxide of iron	0.0169
Hydrochloric acid	0.0100

Besides these constituents, the water contains traces of lithium and potassium. The specific gravity, at 15° C., amounts to 1041.4. Professor Liebermann states that "in view of the fact that both the quantity of the solid constituents and also their relative proportions in the bitter water Uj Hunyadi, correspond generally to the proportions found also in other Offen bitter waters; for instance, in Hunyadi Janos, the same considerations are guiding from a medicinal point of view in forming an opinion of water of the Uj Hunyadi springs. What is striking in the Uj Hunyadi water is the proportion between the sulphate of soda and the sulphate of magnesia which is favourable for a bitter water. The quantity of the latter is the greater. According to all this, I do not hesitate to declare that I know of no stronger or more favourably constituted natural bitter water than the natural bitter water Uj Hunyadi." "Apenta" is agreeable to the palate, can be taken with impunity, and is an exceptionally efficacious aperient.

AN ADJUSTABLE LOCK FOR OBSTETRIC FORCEPS.

This addition to the ordinary forceps has been devised by Mr. Edmond McW. Bourke with the object of enabling the obstetrician to fix or lock the forceps after they have been applied. By its means it is possible, by the turning of a milled head in the one handle, to lock or unlock the forceps in a moment, while by the turning of a similar milled head in the other handle the apparatus can be adjusted to any extent of separation of the blades which may be desired. The forceps can thus be at once fixed in any position, so far as the relation of the blades to one another is concerned, and with equal rapidity released without any assistance and

without any relaxation of the grip with which they are being held.

The locking arrangement consists of a flattened metal bar, which when not wanted lies buried in the handle. On turning a milled head or wheel, through a screw-grooved hole in the centre of which it passes, the bar can be protruded towards the opposite handle, into which its head can be made to lock by a quarter turn of a similar milled wheel on that side. These small wheels only protrude from the handles sufficiently to enable them to be easily turned. The accompanying woodcut sufficiently explains the apparatus. Mr. Bourke's idea has been carried out by Messrs. Arnold and Sons, West Smithfield, from whom the forceps can be obtained.

RHINODYNE.

RHINODYNE, which is recommended as valuable in the treatment of hay fever, is a modified form of the snuff recommended by Dr. Ferriar as a remedy for cold in the head. It contains bismuth subnitrate with a cocaine salt in place of the morphine of the original recipe. It also contains a little menthol and nearly 40 per cent. of lycopodium powder.

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

[SECOND NOTICE.]

THE auxiliary scientific investigations reported in the new volume of the Reports of the Medical Officer to the Local Government Board (see BRITISH MEDICAL JOURNAL, September 21st, p. 72) occupy less space than for some years past. They are concerned chiefly with bacteriological questions.

THE TYPHOID BACILLUS AND THE BACILLUS COLI COMMUNIS.

Dr. Klein, F.R.S., reports the results of further experiments as to the pathogenic properties of the "typhoid bacillus." He directed attention to the question as to the relation which has been supposed to exist between the bacillus coli and the typhoid bacillus. In the last volume of these Reports he gave differential points between the typhoid bacillus obtained from the tissues in enteric fever, and the bacillus coli obtained from the healthy human intestine. Subsequent investigation was directed to ascertain whether the differential characters were modified when these microbes were submitted for equal lengths of time to similar conditions outside the human body. It was found that no modification was produced under the observed conditions. The bacilli were thus tested after prolonged sojourn in sterilised water or ordinary tap water. Opportunity was taken to compare the bacillus coli and the typhoid bacillus obtained from the water supply of Worthing and Rotherham during epidemics in those localities, and in both instances cultures of both bacilli presented the described *differentia*. Intraperitoneal injection of either organism produces in guinea-pigs intense peritonitis with free multiplication of the microbes in the exudations. It was found that in a series of inoculations performed from one guinea-pig to another the differential characters of the two bacilli were not in any respect modified.

THE CULTIVATION OF THE TYPHOID BACILLUS FROM DRINKING WATER.

The difficulty of isolating the typhoid bacillus from a water supply, even when from other evidence it is clear that the water has been the means of the dissemination of disease is well known. The method adopted with success by Dr. Klein was to drive a large quantity of the water (1,600 to 2,000 c.cm.) through a Berkefeld filter, and to use the particulate matter left on the filter for plate cultures, each plate receiving the particulate matter from 160 to 250 c.cm. of water. The gelatine was previously treated with carbolic acid, which retards the growth of the ordinary saprophytic organisms, but not of the typhoid bacillus or of the bacillus coli, which thus have time to form colonies without being overwhelmed by the luxuriant growth of other organisms.

SURVIVAL OF THE TYPHOID BACILLUS IN DRINKING WATER.

It was observed incidentally in the course of the experiments mentioned above that the typhoid bacillus could survive in distilled water much longer than in tap water, whether sterilised or unsterilised before the introduction of the bacillus. In flasks containing distilled water the bacillus, after gradually decreasing in number until the sixteenth day, began again to increase, until at the end of a month colonies could be obtained as readily, and in as large numbers, as on the first day after the introduction. On the other hand, in the flasks containing tap water (sterilised or unsterilised) few or no colonies could be obtained after the sixteenth day. The same phenomena were observed with the *B. coli*. Dr. Klein proposes to pursue this investigation further, with the object of ascertaining the behaviour of these two microbes in waters of various characters under various conditions.

INOCULATION OF TYPHOID FEVER.

Certain experiments were made by Dr. Klein to test whether typhoid fever could be conveyed to monkeys by feeding or inoculation with artificial cultivations of the bacillus. The feeding experiments gave negative results, as did also subcutaneous injection, except in one of the eight monkeys used. In this monkey, which was also at the same time inoculated (accidentally) with erysipelas, of which it

died, the typhoid bacillus was found to have become established and to have multiplied in the spleen. In the case of four calves inoculated with typhoid cultures by subcutaneous injection in the groin, it was found that the neighbouring lymphatic glands contained the typhoid bacillus in considerable numbers when the animals were killed 10 to 14 days after inoculation.

THE ANTAGONISM OF MICROBES.

In the last number of these Reports Dr. Klein showed that the substance of the bodies, the protoplasm, of certain bacteria were poisonous. To this poison he applied the term "intracellular poison," and pointed out that it was to be distinguished sharply from the toxins produced by the same bacteria as the result of their growth and multiplication in the human body or in artificial media. The intracellular poison of the vibrio of cholera, of Finkler's vibrio, of the typhoid bacillus, of the bacillus coli, of proteus vulgaris, and of staphylococcus aureus produced similar or identical symptoms, whereas those produced by their toxins differed widely. Continuing this research, he found that the intracellular substance of the bacillus anthracis, the bacillus diphtheria, and the bacillus of fowl cholera is not poisonous, and does not confer on the animals (guinea-pigs) used for the experiments any immunity.

THE CHEMICAL PATHOLOGY OF TETANUS.

Dr. Sidney Martin, in continuation of his admirable researches on the chemical pathology of certain infectious diseases, now presents a preliminary report on acute traumatic tetanus. The blood, the spleen, and the spinal cord from cases of tetanus were examined chemically, but the present report deals with the blood and the spleen only. From them were obtained albumoses and acid organic bodies. The albumoses were found to produce fever but not tetanic contractions. The acid organic bodies which were contained in the alcoholic extract were divided, roughly, into two classes according as they were soluble or insoluble in ether. The material soluble in ether was found to produce tetanic muscular spasms, and death in certain doses. Dr. Martin concludes, therefore, that the ether extract—that is, the part of the alcoholic extract soluble in ether—contains the substance or substances which are the direct excitant of the muscular spasms in tetanus. The separation of the toxic substance or substances and the determination of their nature will be the subject of further inquiry.

THE BACTERIOLOGY OF VACCINIA.

Dr. Klein contributes a report on the bacteriology of vaccinia, in continuation of that published in the last number of these Reports. Further research has only confirmed the conclusion that, though human and calf vaccine lymph, as well as the clear lymph obtained from human small-pox on the third or fourth day of the eruption, all contained a short bacillus, present in great numbers in early lymph, yet these bacilli cannot be cultivated in any media which has yet been tried. Following on subcutaneous inoculation of active calf vaccine lymph, the lymphatic glands become enlarged in guinea-pigs and calves, and it was thought possible that the bacilli might be present in these enlarged glands and in a state more favourable for cultivation. Experiments were accordingly made in this direction, but again with negative results.

THE BACTERIOLOGY OF A "COMMON COLD."

Dr. Edmund Cautley has examined bacteriologically ten cases of "cold in the head" occurring at a season when influenza was not prevalent. In no case did he find the influenza bacillus, and the microbes found were not constant. In cases examined during the early stage staphylococci were cultivated, but it was not possible to determine the species, in later stages, in addition to staphylococci, moulds and sarcinae were cultivated.

MICROBES IN LYMPHATIC GLANDS.

Dr. Cautley has also made some investigations as to microbes present in lymphatic glands under various conditions in man. In some instances death had been due to accident, in others to acute, and in others again to more chronic disease. Neither in the bronchial nor in the mesenteric glands were large numbers of microbes found;

they were far from being "crowded with organisms." Farther, not all of those present were living. In only two instances was the tubercle bacillus seen (in the bronchial glands) and in both instance there were caseous glands in the neighbourhood. The organisms found in the mesenteric glands were such as are found commonly in the alimentary canal, but "their number and variety" were "surprisingly small." The bacillus coli commune was found in 2 cases only (out of 25 examined). In the bronchial glands the variety of microbes found was somewhat larger, but the number in any case was small, and in a large proportion of cases none at all were discovered. The bacillus coli was present in 5 out of 10 cases in which microbes were found.

PELOSPERMS AND CANCER.

Dr. Klein contributes an interesting critical review of the theory which would trace some causal relationship between pelosperms and cancer. The article is one which hardly bears condensation and should be read by everyone interested in this obscure, but most interesting question. Dr. Klein's arguments, founded as they are mainly on histological considerations, will be received with the utmost respect, even though he calls in question many, in fact the vast majority, of the observations which, it was hoped, might afford some clue as to the etiology of this terrible scourge. In concluding his report he writes:

"All that therefore remains, and cannot be placed to the account of either epithelial cells or their nuclei, or of leucocytes, are the large pedunculated protoplasmic bodies with a nucleated knobbed enlargement, contained within epithelial cells, that were first seen and described by Korotneff, rhophalocephalus carcinomatosus. These seem to me to be large amoeba-like bodies, which, by reproduction, bring forth small nucleated protoplasmic amoebæ generally also contained within epithelial cells. Such small amoebæ offspring, just like the parent amoeba, are conspicuous by their staining, and by their apparent direct connection with the pedunculated large amoebæ. Whether many of the nucleated cells enclosed within the epithelial cells of cancer, seen and described by other observers (Sondakewitch, Ruffer, and others) as conspicuous by their staining are or are not the young amoebæ in question, cannot be easily determined.

"Lastly, it has to be mentioned that the above pedunculated amoebæ have been found by myself in one case only, that of cancer of the œsophagus; I could not find them in many other cancers. It is quite possible that this condition, namely, that of the pedunculated form, may be more difficult to meet with, or may be more rare; the form of smaller, rapidly dividing amoebæ being more frequent. But at all events, even these latter forms are in many cancerous epithelial growths only sparingly to be met with; in some I have missed them altogether, while in others several sections had to be examined in order to find one or the other nucleated bodies resembling them. From this it would appear hazardous to assign to them a definite causative relation to the rapid growth and multiplication of the epithelial cells constituting carcinoma."

DEATHS UNDER ANÆSTHETICS.

CHLOROFORM.

DR. E. HUGH SWELL has furnished us with the following case of death under chloroform which occurred at the Greenwich Infirmary on September 11th, 1895: E. L., a woman, aged 54, was admitted to the Greenwich Infirmary on August 7th, 1895; on September 11th she required an anæsthetic for an abdominal section to be performed by Mr. W. J. C. Keate, Assistant Medical Officer. She had been suitably prepared for the operation, and everything that could possibly be required in the event of any untoward symptoms arising from the anæsthetic was at hand. No organic disease of the lungs or heart could be detected by physical examination; there was no albumen in the urine; there was a history of chronic alcoholism. This latter fact, together with a consideration of the nature of the operation, suggested chloroform as the most appropriate anæsthetic, which was accordingly administered. It was given him on a folded lint with left hand under the lint, the fingers extended, the ring and

little fingers supporting the chin. The right pupil was dilated and irregular on account of old iritis, and it was disregarded during the anæsthetisation; the left was small and reacted to light. The patient held her breath at first and began to struggle; afterwards she talked irrationally; this continued during the whole of the preliminary stages. The pulse at the right wrist was not felt to vary, and was fairly strong and regular. The conjunctival reflex and the delirious conversation disappeared together about seven minutes after the first application of the chloroform; she was then fully anæsthetised, and the lint was withdrawn and not again applied; the breathing was then regular, immediately afterwards it became noisy and then stertorous; the operation had not been commenced. The face began to become livid. The tongue was immediately drawn forward and the chin further upwards; the breathing then ceased altogether, and the face was more livid. Artificial respiration was then resorted to, and the patient made five or six irregular respirations herself. Venesection was performed on the right median cephalic and median basilic veins; only about half an ounce of blood flowed; the breathing not continuing, the artificial respiration was again started. Sylvester's method being employed; amyl nitrite was held to the nose, ether and strychnine were injected hypodermically, heart puncture and inversion were tried, and the artificial respiration was continued for half an hour, but all to no purpose; life was then seen to be extinct, and further efforts hopeless. About 2 drachms of chloroform (Duncan and Flockhart's) had been used, though since the two sides of the lint had been used alternately this is largely in excess of that which had been inhaled; the pulse was felt until the respiration ceased; during the efforts at resuscitation its beats were not felt for, nor the heart listened to, until the lapse of some ten minutes, when the pulse could no longer be distinguished nor the heart heard. The method of death appeared to be due to asphyxia; five medical men who were present concurred in this opinion. Necropsy on September 12th: The deceased was a very stout woman; meninges congested, brain normal; a large amount of dark fluid blood escaped from the cut cerebral vessels. Heart flabby, 10½ ounces, walls soft and fatty degenerated; mitral orifice admitted three fingers easily, and the valves were slightly thickened at the edges; the tricuspid orifice admitted four or five fingers; the sub-pericardial tissue contained extensive deposits of fat. All the cavities of the heart were quite empty of blood-clot or blood, the lungs were very much engorged with blood, otherwise normal; the larynx and trachea were free, containing no foreign body; liver fatty, kidneys very slightly granular, some cystic tumours connected with one ovary. At an inquest held on September 18th, the jury returned a verdict that "death was due to asphyxia brought on by chloroform, properly administered, for the performance of a necessary operation."

Mr. E. V. R. Fooks, M.R.C.S., L.R.C.P., Acting Medical Superintendent to the Infirmary, East Dulwich Grove, London, S.E., has favoured us with the following notes on a case of death under chloroform which occurred in that institution: C. H., aged 14, was admitted on June 5th suffering from tuberculous glands of the neck, which had broken down. These had partly healed, but broke down from time to time, leaving an intractable sinus which would not heal, so that on September 11th it was deemed necessary to scrape the sinus, for which purpose the patient, after being examined and no organic lesions found, was put under chloroform at 11.35 A.M., having been prepared in the usual way. The chloroform was administered on lint by the gradual method. The patient took it very well at the commencement, but after nearly 2 drachms had been administered began to struggle and got slightly blue at the lips. The chloroform was immediately stopped; the pulse was found to have become very weak, and soon afterwards imperceptible; respiration still continued. At the first sign of heart failure strychnine was injected hypodermically, and as no improvement took place she was suspended by the legs. Respiration getting weaker ether was injected, and artificial respiration was commenced and the battery applied over the vagus and precardial region. These means proved of no avail, and respiration ceased altogether. From the time of starting the anæsthetic until

respiration ceased was about twenty-five minutes. Artificial respiration was continued for one hour and twenty minutes, during which time the patient made one feeble respiratory effort. The pupils reacted well until shortly after cyanosis commenced, and then became dilated. The operation had not been commenced. Owing to a misunderstanding between the sister and one of the medical officers consent to perform the operation had not been obtained from the parents. On a post-mortem examination being made the right ventricle of the heart was found dilated and full of fluid blood, cerebral vessels congested, and a few old adhesions at the bases of both lungs; otherwise all organs were healthy.

THE MASSACRES IN CHINA.

THE WOUNDED SURVIVORS OF THE HOA SANG MASSACRE.

Dr. T. RENNIS sends us from Foochow the following account of the wounded survivors of the Hoa Sang massacre, which took place between 6 and 7 of the morning on August 1st:

Nine adult British subjects were brutally murdered, and of the eight European survivors seven were more or less seriously injured, whilst only one, who lodged in a native house situated some distance from the two English cottages, escaped unhurt. This gentleman, the Rev. H. S. Phillips, was thus fortunately able to staunch bleeding and in great measure alleviate the sufferings of the wounded until medical aid could be procured. About 8 p.m. on August 1st Dr. Gregory, of the American Methodist Mission, Kuehng, arrived to treat the wounded. After this had been done, owing to difficulties in procuring chair bearers, it was not till 4 p.m. on August 2nd that Dr. Gregory with his charge could leave Hoa Sang for Foochow. Three hours after commencing the journey H. S., a boy of 6 years, died. Besides being severely wounded about the upper parts of his body he had received several severe wounds on the head, one of which clove the occiput and exposed the brain.

At 8.30 a.m. on August 3rd, after travelling in native chairs for 30 miles, Dr. Gregory with his charges reached Chwi Kau, a village on the left banks of the river Min. There the wounded were transferred to native boats, and at 2 p.m. on August 4th Foochow was reached. Miss H., an American lady, was taken to the American Methodist Mission Hospital, whilst the rest of the wounded, five in all, were placed under my care in the private wards reserved for Europeans adjoining the Foochow Native Hospital. Their condition on admission was as follows:

Miss C. had a sword wound across the vault of the cranium 1 inch behind the anterior margin of the hair, 4 inches long, and extending down to the bone. The edges of the wound, except at two points where thick sanious pus exuded, were healed. Through the openings rough bare bone could be felt with the probe. Dr. Gregory told me that when he dressed this wound at Hoa Sang, on the evening of August 1st, he had removed several loose fragments of the external table of the skull. An incised wound 7 inches long commenced at the left angle of the mouth, passed downwards and backwards over the lower jaw on to the neck, cutting through the whole thickness of the lip, and exposing the inferior maxilla. Good union had taken place throughout the greater extent of the wound; but a large scar will remain. The thrust that had inflicted this wound had broken off the left upper lateral incisor tooth at the margin of the gum, leaving the sensitive dental pulp exposed. Of other incised wounds of importance one, five inches in length, ran across the bridge of the nose under the right eye; whilst another, four inches long, ran along the lower border of the right inferior maxilla. There was considerable ecchymosis of the right eyelids, much photophobia of the same eye was complained of, and the episceral vessels were deeply injected. Generally, over the head, there was much pain and discomfort, and when the head was shaved two punctured wounds of the scalp and numerous contusions were exposed to view. In other parts of the body ten shallow punctured wounds were counted. Miss C. was suffering from insomnia and slight symptomatic fever.

M. S., aged 12, had a sword wound 6 inches long, which commenced an inch and a-half to the inner side of a point 3 inches above the middle line of the right patella, passed outwards and downwards, and ended

at the junction of the inferior and middle thirds of the outer edge of the patella. The wound had a slanting direction outwards and backwards, was very deep for its lower four inches, and passed through the outer two-thirds of the rectus femoris, part of the crureus, and the greater part of the lower attachment of the vastus externus. I did not see any opening into the joint, but Dr. Gregory told me that when he first dressed this wound he had clearly seen part of the articular surfaces of the joint. Excepting for about two inches at the upper part, the wound had not healed. The whole joint was considerably swollen. A cavity from which thick sanious pus welled out, about the shape and capacity of an average-sized middle finger, extended upwards from the lower part of the wound just external, I think, to the lower aponeurosis and deep fascia of the vastus externus. There were besides two punctured wounds—one on the left leg and another on the left foot. When the head was shaved two punctured wounds and several contusions on the hairy scalp were discovered.

Her temperature was 102° F., but as there was no suppuration in the cavity of the joint it was deemed advisable to attempt, by treating it on antiseptic principles, adopting means to render the joint immovable, and to reduce the inflammation present to save the articulation.

K. S., aged 11, had, on various parts of her body five punctured wounds and several superficial bruises.

E. S., aged 4, had an incised wound on the left buttock, a punctured wound on the left arm, and was much bruised about the head. His wounds were not of a serious nature; but he suffered much from insomnia and nervous prostration.

H. S., aged 13 months, had a punctured wound about the middle of the left frontal bone one inch anterior to the margin of the hairy scalp. Thin sanious pus was exuding from the opening which, on examination, was found to enter the cranial cavity by an incised wound in the skull. Judging from the extent of the external wound and the formation of a native spear the contents of the cranium could not have been punctured more than one-half inch. A severe blow had been inflicted on the right eye. The upper eyelid was much ecchymosed and swollen. The palpebral conjunctiva at the inner part of the lower eyelid was torn from the adjoining scleral conjunctiva. The pupil was widely dilated, insensible to light, and the iris was lacerated. Backwards and upwards for several inches from the right ear there was an extensive contusion. A severe bruise ran diagonally across the right chest from the shoulder to the lower end of the sternum. The child's temperature on admission was 103° F. An attempt was made to render the cranial wound aseptic, and measures were taken to subdue and prevent extension of inflammation in the cranial cavity. In all the wounds seemed to have been inflicted by means of spears, swords and sticks.

AMBULANCE INSTRUCTION FOR SAILORS.—At a large gathering of merchant sailors in the Mission to Seamen's Institute at Poplar, on September 19th, a presentation of St. John Ambulance certificates was made. In the uncertain intervals of their voyages hundreds of seagoing men have, during the first year of the existence of the Seamen's Institute, received partial instruction in first aid to the injured from Dr. Radford, of the London Hospital, assisted by Mr. Noble, the Missions to Seamen reader. Fifty-nine of these sailors have been long enough ashore to complete the prescribed course of ambulance instruction, and to pass successfully the examinations held by Dr. Tunstall, of the volunteer forces. Already many of the certificated men who have gone to sea have had many occasions of putting their ambulance training into practice in consequence of severe accidents on board ship.

The report of the Harvard Medical School issued recently states that the influx of students has not been appreciably diminished by the extension of the course to four years. There were altogether in the academic year 454 medical students, of whom 182 belonged to the first year's class. The resources of the class rooms and laboratories are, it is said, likely to be strained if the new entries continue to be as numerous or to increase, and it is seriously proposed to meet this difficulty, not by increasing the accommodation, but by extending the curriculum to five years.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office Orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, SEPTEMBER 28TH, 1895.

THE SIGNS OF DEATH.

THE question of the possibility of the interment of living beings has recently been exercising the minds of a portion of the public, whose fears have found expression in a series of letters to some of the daily papers. It is a matter of regret that so much irresponsible nonsense and such hysterical outpourings should find a place in the columns of our great daily press. No attempt at the production of evidence in support of their beliefs or fears has been made by the majority of writers, whilst the cases mentioned by the few are either the inventions of the credulous or ignorant, or are destitute of foundation. It cannot be said that the few medical men who have joined in this public correspondence have either contributed any useful information or have seriously attempted to allay the fears of the public. One medical gentleman managed to earn for himself a cheap notoriety by employing, with very scanty acknowledgment of the source, copious extracts from Dr. Gowers's article on Trance in *Quain's Dictionary of Medicine*.

The possibility of apparent death being mistaken for real death can only be admitted when the decision of the reality of death is left to ignorant persons. We are quite unprepared to admit the possibility of such a mistake occurring in this country to a medical practitioner armed with the methods for the recognition of death that modern science has placed at his disposal. Moreover, even by the ignorant the reality of death can only be questioned during the period preceding putrefaction. During this period various signs of death appear which, taken collectively, allow of an absolute opinion as to the reality of death being given. To each of these, as a sign of death, exception may perhaps be individually taken, but a medical opinion is formed from a conjunction of these signs, and not from the presence of an individual one.

The various conditions or forms of disease which may occasionally to the casual observer closely simulate death are syncope, coma, concussion, hysterical spasm, catalepsy, and exhaustion; but in these cases the warmth of the body is retained, and the heart and lungs continue to act, although perhaps but feebly. Catalepsy or trance, and profound sleep lasting for a lengthened period, are conditions somewhat similar to the hibernation of animals. To a casual observer a hibernating animal would appear to be dead, but the vital functions are not arrested, but are reduced to a low ebb; the

pulsations of the heart and the respiration still occur, though feebly and at lengthened intervals. In like manner the authenticated cases of catalepsy and prolonged profound sleep that have been recorded by medical men, though presenting to the ordinary observer the appearances of death, have always yielded on careful auscultation evidence of the action of the heart and lungs, although the heart's action may have been very slow and feeble, and the respiration reduced to only four or five per minute. The very exceptional case of Colonel Townshend, who apparently possessed the extremely rare power of partially suspending, by an act of volition, the action of the heart, cannot even be taken as an exception to what has been stated above. It appears that Colonel Townshend possessed the power, by a mere effort of will, of so suspending the action of the heart that he was able to pass into a profound sleep, or condition of stupor, in which no radial pulse could be felt, no beating of the heart was perceptible by palpation, and no moisture condensed on a bright mirror held to his mouth. These, however, were but rough tests of the existence or not of respiration and circulation. It must be remembered that, at that time, the stethoscope was not invented, and that Colonel Townshend's heart must, in all probability, have been beating, although but feebly, and his respiration continuing, during the time he was in the senseless condition, a period which usually extended over half an hour. A few hours after one of these experiments, however, the Colonel died.

The signs on which a medical man should rely as furnishing the best evidence of the reality of death, prior to the commencement of putrefactive changes, are: (1) The absence of circulation and respiration; (2) the gradual cooling of the body, the extremities cooling first and the trunk last; (3) gradual supervention of rigor mortis; (4) the production of *post-mortem* stains or ecchymoses. The auscultatory test was first proposed by Bouchut, to whom the French Academy awarded a prize in 1848 for the discovery of this proof of death. Bouchut found that in all cases of apparent death, although the contractions of the heart were reduced in force and frequency, auscultation enabled him to detect the pulsations of the heart, and so to distinguish apparent from real death. The careful use of the stethoscope by a medical man will enable him to distinguish a living from a dead body.

The statement is occasionally made that certain forms of rigidity that may occur during life may be mistaken for rigor mortis. Rigidity during life may occur from tetanus, apoplexy, catalepsy, syncope, asphyxia, and hysterical spasm, but presents these three striking differences from cadaveric rigidity: (1) The warmth of the body is preserved. (2) The whole of the body becomes equally rigid at the same moment, due to the occurrence of a general muscular spasm; whereas, in connection with rigor mortis, the rigidity usually commences in the muscles of the neck and lower jaw, and then gradually affects the other parts of the body. (3) If a joint be forcibly bent, such as the arm at the elbow, the limb will, if in a state of spasm from disease, return to its original position when the bending force is removed, whereas if it be in a state of rigor mortis it will not.

From time to time the public mind is agitated by the fear of premature interment, and undoubtedly in past times, when medical men did not have at their disposal the

methods for the recognition of death which they now possess, living individuals may have been consigned to the grave. But in recent times all cases of alleged premature interment in this country have, upon close examination, proved to be nothing more than the delusions of superstitious or ignorant people, with a considerable amount of exaggeration added. The fact of an exhumed body being found turned in the coffin is no proof of premature interment, since such movement may have been caused by tilting or turning of the coffin during its conveyance to or lowering into the grave, or may be the result of gaseous distension of the corpse from putrefaction. The pressure exerted by the generation of the gases of putrefaction is responsible for many phenomena which are apt to be regarded as vital ones by the uninitiated. Thus the pressure of the gases of putrefaction within the alimentary tract may cause a *post-mortem* escape of alimentary and faecal matters from the outlets; and, in the cases of women who have died during labour and undelivered, the gases of putrefaction have even accumulated with sufficient force to expel the contents of the uterus on certain rare occasions. Again, various blood displacements may occur from the pressure of the gases of putrefaction generated within the heart and blood vessels causing *post-mortem* hæmorrhage from wounds, or changing the pallid face of a corpse to a red and rosy colour.

As burial is carried out in this country, and assuming that a person still living has been screwed down in an air-tight coffin, it is quite impossible to believe that such a person could ever recover consciousness, since speedy asphyxia must result from the accumulation of the products of respiration in the small amount of air within the coffin. With regard to the recorded cases of alleged death where the individuals supposed to have died have yet retained consciousness so as to overhear conversations, although unable to make any movement at the time, these have proved on investigation to be cases in which the reality of death has been wrongly assumed by ignorant persons and in which no examination as to the occurrence of death has been made by medical men. There is no certain and simple sign which would be of use in guiding ignorant persons to decide on the reality of death soon after it has occurred, nor is it, perhaps, desirable that such should be discovered, as it would be always dangerous to leave the decision of such a question to ignorant people. It is better that the rule should be strictly enforced that nobody should be buried without a medical certificate of death and its causes. To avoid the possibility of hasty interment of the living as dead no burial should be allowed to take place until after the lapse of twenty-four hours at least from the time of the supposed death, and only then upon the certificate of a medical practitioner who has examined the body.

If a proper interval be allowed to elapse after the supposed death there should be no difficulty in deciding the question of the reality of death prior to the commencement of putrefactive changes. If the signs of death, previously detailed, are observed, then, quoting the words of Taylor and Stevenson, "these changes are as certainly the forerunners of putrefaction as the process of putrefaction is itself the forerunner of the entire destruction of the body."

A "SYMPHILOLOGICAL CONGRESS" will, it is announced, be held at St. Petersburg in November, 1896.

THE PARLIAMENTARY COMMITTEE ON ADULTERATION.

THE second report of the "Food Products Adulteration" Committee of the House of Commons consists chiefly of a record of the evidence given by representatives of various trades and trade organisations, and, although, as might have been anticipated, it contains a not inconsiderable amount of matter of very doubtful accuracy and value, the report, taken as a whole, and intelligently read by those who may be able and willing to separate the wheat from the chaff, must be regarded as a most important public document. The adulteration question is one upon which profound and widespread misconception exists, and even among those who have given life-long attention to the subject there are still great differences of opinion as to the best methods of dealing with it.

The technical details, scientific and legal, which the matter involves, the complicated commercial questions which are affected, the vast commercial interests which are at stake, and the undoubted, but by no means always clear connection between adulteration and the health and well-being of a community are considerations which may well make any would-be legislator pause before settling about the production of any ameliorating legal scheme, until the subject has been threshed out to a far greater extent than can at present be said to be the case. As we have repeatedly urged, fresh and comprehensive legislation dealing with the adulteration, both of food and of drugs is absolutely necessary, and although the Parliamentary Committee's report does not contain much information as to adulteration practices beyond that which has been reported for years past by public analysts in this country and abroad, it is satisfactory to find our frequent contention thoroughly justified by the facts recorded in a Blue Book upon which forthcoming legislation must be partially based.

The Committee have had placed before them a number of facts relating to the adulteration of milk by the admixture of separated milk, the addition of water, the direct abstraction of fat, and the addition of colouring matters and "preservative" chemicals, all points upon which we have frequently animadverted and in regard to which a recent investigation carried out for the BRITISH MEDICAL JOURNAL has thrown considerable light. The adulteration of butter with margarine, and the substitution of the latter for the former, together with the methods employed to accomplish these ends to the satisfaction of the cheating wholesale and retail dealer; the sale of "filled" cheese, of chicoried coffee, of exhausted ginger, refuse pepper, diluted spirits, salted beer, aniline-dyed sugar crystals, factitious olive oil, and spurious drugs are all matters which have engaged the attention of the members, albeit these subjects have been presented to them in a somewhat incongruous jumble, and in some instances have been dealt with by witnesses whose evidence was too obviously influenced by personal considerations, or who were not very thoroughly acquainted with the matters upon which they were desirous of enlightening the Committee.

The Committee of the House of Commons, upon whose report the Sale of Food and Drugs Act, 1875, was principally based, came to the conclusion that in regard, at any rate, to the adulteration of food, the public were cheated rather than

poisoned; and that the same conclusion may be drawn from the report now before us is so far satisfactory. But it must be remembered that this could not be said about the adulteration practices of thirty or thirty-five years ago, and the state of things which then existed may well be taken as an earnest of what the public may expect in the complete absence of deterrent legislation; although it is only fair to say that the grosser and actually poisonous adulterations of those days were in some cases as much the result of ignorance as design. But while the deterrent effect of the existing law, imperfect as it is, and the great good done by its stringent application, and even by but little more than its mere existence where it is scarcely applied, were freely acknowledged before the Committee, the complaint was made that in many counties and boroughs the Act is a dead letter; and it was strongly urged that fresh legislation should make the taking of an adequate number of samples compulsory in every county and borough throughout the country and in every district in the metropolis. That this should be so no one can doubt, nor can there be any question as to the desirability of bringing the wholesale dealer and manufacturer within the operation of the law, a thing which cannot be satisfactorily accomplished under the existing Acts.

It is gratifying to find, from the evidence given by representatives of some of the largest and most important trading and manufacturing firms in London and the provinces, that the work done by the English public analysts is acknowledged to have been of great value, and almost invariably fair and accurate, by those persons who would necessarily be the first to complain were the facts different. At the same time it is contended, and very properly so, by witnesses whose high commercial positions lend considerable weight to their remarks, that care should be taken that all appointments should be held only by highly qualified men, and that in all cases at least the qualification granted by the Institute of Chemistry should be insisted upon as a *sine quâ non*.

We propose to deal in a more detailed manner with certain points of the report upon a future occasion. In the meantime we think it may be confidently asserted that the work has been well begun, and that the first step has been taken towards the framing of such legislation as will enable a really firm control to be exercised over the adulterator of food and drugs and over both the wholesale and retail vendors of his products.

SO-CALLED "TEMPORARY INSANITY" IN RELATION TO SUICIDE.

In cases of suicide it is a very common occurrence that the coroner's jury acting in the matter returns a verdict of "suicide during temporary insanity," when there is practically little evidence to bear out the fact of the existence of temporary insanity, and in some instances no evidence to that effect worthy of the name. That this, often at least, is done out of amiable motives and in order to spare the feelings of the relatives of the deceased is undeniable, but is not a satisfactory reason for the course in question being pursued. The jury is empanelled to make and give a true verdict and according to the sworn evidence brought before the coroner's court, and the jurymen themselves are under oath to perform their duties just in that way. The verdict

found by the jury, therefore, should be a true one and based solely on the evidence brought forward and established in a satisfactory manner. No verdict should contain an allegation of the "insanity" or of the "temporary insanity" of the suicide, unless or until the fact has been fairly established.

Next, as to the legal relations of suicide and attempts at suicide. Various propositions have been made on this subject, and some of them recently in the *Westminster Gazette*. It would be too much to hope for unanimity on a topic of this kind. On the whole we do not think any very sweeping changes in the law on the subject would be likely to have good effect. But it is eminently desirable that each case of suicide, and of attempted suicide, should be dealt with on its own merits or demerits.

To do away with the legal criminal bearings of suicide would be to loosen or remove the chief check on suicide, in at least some instances; and the time is not yet ripe for ceasing to view suicide as a crime.

And on the other hand, to treat every suicide or suicidal attempt as proof of dangerous insanity; to be followed, in every case of unsuccessful attempt, by reception into a lunatic asylum; is a suggestion which does not commend itself as advocating a proceeding at all adapted to secure the necessary discrimination which should be exercised in the disposal of such cases; and if carried into effect it would turn the asylum into a prison for the reception of such would-be suicides as are not insane.

A PORTRAIT bust in bronze of the late Dr. Robert Brown, the famous botanist, who by Humboldt was termed "*botanicorum facile princeps*," has just been handed over to the Montrose Town Council, the memorial being the gift of a kinswoman of Dr. Brown, Miss Paton. It has been placed in a niche in the house where Dr. Brown was born in 1773. For long Dr. Brown, who died in 1868, was Curator of the botanical collection in the British Museum, and was President of the Linnean Society.

DR. HUGHLINGS JACKSON will be presented with the portrait, which has been subscribed for by many friends and admirers of his eminent services to neurology, on Tuesday next, October 1st, at 3 p.m. The ceremony, which will take place in the Library of the London Hospital Medical College, will be performed by Sir James Paget, who will subsequently distribute the prizes to the medical students and nursing probationers.

THE artificial preparation of human milk is of such moment to the many children fed on that of donkeys, goats, and cows that the reported success of Dr. Backhaus in concocting it is of importance. Cow's milk is fermented by means of rennet and the serum obtained carefully sterilised and enriched as required for different individuals by the addition of cream. The sterilising of milk before distribution is insisted on by Dr. Backhaus. But we should imagine that in Berlin, at least, ordinary cleanliness is required quite as much, if his calculations are even approximately correct that the milk supplied to the Prussian capital is so foul as to compel the Berliners to consume in this way 300 cwt. of cowdung per diem. This amounts to more than the conventional "pound of dirt in a lifetime."

THE LISKEARD BOARD OF GUARDIANS.

In January of this year the Local Government Board sent a condemnatory report from its inspector to the guardians, and requested them to set their house in order. At the Sep-

tember meeting of the Board we read that the Board is still in consultation how to avoid doing that which it is their duty to do, and as we cast our eye back upon the progress of events since the January meeting it is one tissue of reference backwards and forwards from one body to another in the most approved style of obstruction. We wonder that public bodies do not put a little more energy into their conduct of business, remembering that money is not the only commodity to be saved. A new infirmary will have to be built sooner or later, and surely it is true economy to set about it at once.

ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.

THE new hospital on the south side of the meadows is now fast nearing completion, and it is hoped that it may be possible to open it next month. Her Royal Highness Princess Henry of Battenburg has been pleased to undertake the opening ceremony.

POISONING BY LABURNUM SEEDS.

EVERY summer a certain number of children are poisoned by eating the pods of the laburnum tree. We publish on p. 778 interesting notes of such an occurrence by Mr. Hedley Tomlinson, of Gateshead, and by Dr. McNaughton, of Arbroath, and it was recently reported in the public press that more than thirty of the younger scholars at the Melvin Road Board School, Penge, were recently more or less seriously affected by eating laburnum seeds. The report adds that the prompt administration of emetics obviated danger. We have heard nothing further of the occurrence and suppose that the consequences have not been serious, but it might have been otherwise. It cannot be too widely known that every part of the laburnum is poisonous, and many deaths have occurred among children both in this country and on the Continent through eating the seeds or the flowers. A single seed is sufficient to cause violent vomiting, and a dozen flowers have the same effect if chewed. The young shoots are strongly purgative, yet it is said that they are a favourite food of rabbits and hares. The deleterious properties of this plant are due to the presence of one or more alkaloids, cytisine and laburnin. Chevalier and Rassaigue have the credit of discovering the former and Husemann and Marmé the latter.

INSANITARY BOARD SCHOOLS.

DURING a recent School Board election in London much political capital was made out of the discovery of gross defects in the construction of drains and the proved connection therewith of sundry outbreaks of diphtheria, especially in the case of the Yarrow Street Schools, the blame being laid on the late architect, the contractor, or the officials of the Board according to the predilections or prejudices of the several parties. The question of the sanitary arrangements of public elementary schools seems to be in a very unsatisfactory position. Plans and estimates for the erection of new or the enlargement of existing schools are, indeed, submitted to the Education Department, which retains the services of an architect, at a salary of £800 a year, presumably for the purpose of examining and approving such plans, though he probably confines his attention to the accommodation proposed and the number and cubic space of the class room. Her Majesty's inspector, at his annual visit, is supposed to satisfy himself as to the sanitary condition of the schools, by which he probably understands outward cleanliness and decency. In either case the arrangements seem to be left very much to the discretion of the builder as beneath the notice of the Board or their architect. In the recent outbreak of diphtheria at Bedding near Merthyr, there can be no doubt as to its origin in, as well as its diffusion by means of, the new Board schools. With the exception of twenty old wooden cottages, damp and confined, with privies and cesspits in their rear, the

village, with its industrial and mining population of 1,500, consists of substantial and airy stone-built houses, with a good sewerage system and water supply; but though incidence of the epidemic, which lasted from April to August, was heaviest among the occupants of the "huts," it was by no means limited to that locality, and the sporadic cases occurring between December and March were all in other streets. In every instance the first cases in a house or family were children attending school, those among older or younger children being invariably subsequent or secondary. In all, excluding occasional cases during the previous winter, 78 cases were reported, 61 of these being children attending school. The schools themselves are spacious modern buildings, and in every respect, save one, leave nothing to be desired; but the sanitary conveniences consist of two series of trough closets, with an automatic flushing cistern and an untrapped drain leading to cesspits hewn out of the pervious sandstone rock, with no cement lining or aperture for emptying or even ventilation. They are, in fact, so constructed as not to need emptying, the fluid part of the sewage soaking away into the rock. But, in the absence of any exit, a volume of the foulest gases, displaced by the flush, finds its way into the closets connected with the schools every time the cistern discharges itself. Such "bottomless pits" were once general in sandstone and limestone districts; but, even supposing that the local architect knew no better or was overruled by an ignorant Board, we have a right to know, in the interest of the millions of children in public elementary schools, whether the control claimed by the Education Department over these buildings does or does not extend to their sanitary arrangements, and, if it does, how such a place—and we know not how many more of the kind may be in existence—could pass or be allowed to pass the architect's department at Whitehall.

APPOINTMENTS OF NURSES.

As a sequel to our discussion on this subject, it is evident from the advertisements for trained nurses that some of the metropolitan workhouses are either increasing the nursing staff or adding the trained nurse to their list of officers. St. Matthew's, Bethnal Green, is making large additions to the staff, and we gathered that a nurses' home forms part of the scheme; but we are sorry to see that the nurses seem to have entire freedom in the selection of their lodgings, which is hardly a wise arrangement on the part of the Board. Hackney Union also is advertising for nurses, which is a move in the right direction; this infirmary having been somewhat behind in this particular. Poplar and Stepney are appointing a sister for the Sick Asylum at Bromley, also staff nurses; we fear, however, that the Board will experience some difficulty in filling these posts, the salaries offered—£24 for the sister, £20 for the nurses—being quite below the usual standard.

DOCTORS AND THE LAW.

UNDOUBTEDLY the medical curriculum embraces a wide range of study, and we would be the last to suggest the addition to it of any unnecessary subjects. We would, however, urge upon young practitioners that after qualification they might well fill up that superabundance of leisure with which they are credited while waiting for patients by a careful study of their relations to various officers of the law and of their duties in those positions of medico-legal responsibility which are sure sooner or later to be thrust upon them. Such a study would often save a man from ridicule and from placing himself in a false position. For example, he would find among other things that a coroner can call what medical evidence he likes, subject to the jury being satisfied on the subject. Yet it is clear that numbers of medical men do not understand this simple fact, and feel aggrieved when others are called in cases in which they have been engaged. So far does this misunderstanding go that in

a case reported in the *Daily Telegraph* of September 24th a medical man who was the first sent for to a case of suicide, but not the first to arrive, when summoned to the inquest offered the fee to the other man. Courteous no doubt, but quite unnecessary. Still more unnecessary, although not so courteous, were the remarks made by the other medical man on the subject. A little study of the duties of witnesses and the functions of the coroner would have saved this gentleman from an unpleasant rebuff. It cannot be too carefully remembered that a medical man called to a coroner's court has no status except as a witness, first, as to facts, and, secondly, as to opinion in regard to such facts as are given in evidence. Directly a medical witness goes beyond this duty, or enters upon extraneous matters, he exposes himself to unpleasantness, any attempt to illustrate his evidence or explain his words being fatal; yet this is just what many men love to do.

THE EAST END WATER QUESTION.

THE stars in their courses appear to be fighting against the East London Water Company. A baby was recently found drowned in a water tub in a backyard in Mile End. The mother of the child stated at the inquest that she was obliged to fill the tub because the water was cut off at night, and there was no storage cistern on the premises. Whereupon certain gentlemen of the jury seemed inclined to attribute the death of the child to the breakdown of the constant supply of water. This somewhat far-fetched view has not been allowed to pass without criticism, and in a letter to a contemporary a correspondent defends the water company, and insists that it is the duty of landlords to fix cisterns in houses let to tenants, and that poor people waste a great deal of water, and so on. The moral of all this appears to be that it is desirable some understanding should be arrived at as to what constitutes "a constant supply." It has been supposed that given a constant supply, there is no need for a storage cistern. Now we are told that this view is absurd, and that whether the supply be constant or not, a cistern is necessary to meet cases of emergency. The official inquiry which is to be instituted, will perhaps enlighten the people of East London and Londoners generally on this point.

NUNS AS NURSES IN IRELAND.

WE referred last week to the circumstances of the dispute between the Local Government Board and the Athlone Board of Guardians, who refused to have one of the Roman Catholic sisters trained in a Dublin hospital before taking up the duties of a night nurse. The Local Government Board has acted with promptness, and has dissolved the Board of Guardians by sealed order. Two vice-guardians will now be appointed at a salary of £250 a year, so that the ratepayers will have to pay £600 a year until a new election takes place. There are no fewer than sixty-seven workhouses in Ireland where the nursing is controlled or carried out by the nuns. These ladies, excellent in their devotion to charitable work, have not as a rule received what is understood as hospital training. We are extremely sorry that any difficulty has arisen in regard to them; but we hope that wise counsels will prevail, and that their advisers will see how necessary it is that modern requirements in regard to nursing must be met.

THE BRITISH ASSOCIATION IN CANADA.

A CORRESPONDENT writes: Toronto is jubilant over the decision that the British Association for the Advancement of Science should hold its annual meeting in 1897 in that city. If the British Association can successfully hold its annual congress in Canada, why should not the British Medical Association do the same? In Canada we have flourishing Branches in Montreal, Toronto, and Winnipeg. Though separated by a wide strip of ocean, Canada and England are one country, and the British Medical Association there and here is one body.

There is nothing which draws together more closely the bonds of union than meetings, out of which grow personal friendships and mutual understanding and respect. Distance is now nearly abolished by steam, and the old dangers of travel have been swallowed up in the comfort and ease with which a journey is undertaken in one of the big liners. We might even anticipate meetings in our distant Branches in Australia, India, Canada, and the Cape, so that the British Medical Association may become not only coextensive with the great British empire, but may extend the aid and support of membership and corporate existence to medical men toiling solitarily in remote colonies and dependencies. The British Medical Association is not confined in its members, and should not be in its annual meetings, by the narrow limits of Great Britain and Ireland.

THE SICK POOR IN IRISH WORKHOUSES. SOUTH DUBLIN UNION.

OUR Special Commissioner reports that the South Dublin Union Workhouse is regarded as a model to other institutions of the kind. Is it that size is considered as in itself a merit? The advantage of crowding over 3,000 paupers of all classes into a single group of buildings, with insufficient air space round them, is more than doubtful. These barrack-like buildings, even when not overcrowded, are now known to be a mistake. The various classes of inmates should be separated and treated according to their needs under distinct administration, not herded under one indiscriminate and cast-iron rule. Moreover, we refer our readers to the report itself that they may judge how far this self-complacency is justified in detail. The whole workhouse is disgracefully overcrowded and understaffed; there is no trained nursing except in one department, and in all departments pauper help is extensively used; the infirm are locked in at night without any attendance at all; there are no wards for isolation; the sanitary arrangements are insufficient; the nursery sordid and lacking proper control and supervision. And this is a model workhouse! Truly the guardians and the Irish Local Government Board are easily satisfied.

THE BARIUM WATERS OF LLANGAMMARCH.

THE barium spring of Llangammarch Wells, Central Wales, deserves to be more widely resorted to than is yet the case, though it has been for some years growing steadily in favour. The water, which is from a deep spring, contains a little over 6 grains of chloride of barium to the gallon. This salt, when taken internally, reduces the frequency and increases the force of the heart's action, without raising arterial tension to the same extent as digitalis. As the waters are also rich in other salines (chiefly chlorides of sodium, calcium, and magnesium) they can be used with advantage for baths in those cases of heart disease which are likely to be benefited by a course of the Nauheim waters combined with the exercises employed by Dr. Theodore Schott and his brother the late Dr. Augustus Schott of Nauheim. A course of baths, combined with a moderate internal use of the water at Llangammarch and the special exercises, is likely to be of great use in cases of inefficient cardiac action, whether associated with obvious valvular disease or not. The effect of the baths of saline water is to produce a degree of cutaneous stimulation affecting the cutaneous nerves, and also the vasomotors in such a way as to produce a dilatation of the capillaries over the whole surface of the body. The stimulation of the cutaneous nerves, which probably exercises its beneficial action in a reflex manner, appears to have a persistent effect. However this may be, there can be no doubt that in many cases of cardiac disease accompanied by dilatation, the slowing of the heart, the increase of its force, and the general improvement in the efficiency of the circulation, which are very marked during the bath, do not pass away entirely at its completion, but that after each bath a certain proportion of the improvement

remains as a permanent gain. This is evidenced by the diminution of the pulse rate, and by a decrease in the area of cardiac dulness. The influence of the barium salt taken internally in slowing and strengthening the heart comes in to reinforce the beneficial action of the baths. Cases of cardiac debility secondary to influenza have been treated at Llangammarch during recent years with much success. Llangammarch lies in a broad valley, some 600 feet above the sea, between which and it is mountainous country. The air is thus fresh and invigorating, so that invalids and persons suffering from overwork commonly regain appetite and quickly recover strength. The surroundings are agreeable. There is a picturesque lake on which boating can be enjoyed; the river Irfon affords salmon and trout fishing, and the pump house and hotel have been built with due regard to modern sanitary requirements. It should be added that the water appears to be very constant in composition, analyses made at an interval of ten years showing only very slight differences. As the quantity of chloride of calcium is considerable (about 85 grains in the gallon), the water has been tried in cases of strumous enlargement of the glands, and has yielded good results. Altogether Llangammarch is an interesting spring, which is likely to become better known in the near future.

THE INTERNATIONAL CONFERENCE OF RAILWAY AND MARINE HYGIENE.

We publish in this issue a report of the above conference held last week at Amsterdam. While selecting a distinguished ophthalmologist as President it was the desire of the promoters not to limit the scope of their inquiry to the question of eyesight, and it will be observed from our report that other topics received consideration. All that was desired on this occasion was an opportunity for discussion, and no attempt was made to frame international codes or postulate demands. The Conference, though small, was thoroughly representative, and produced a valuable interchange of opinion. The transactions will shortly be published, and intending purchasers would do well to apply early to Dr. Pijnappel, Stadhouderskade 60, Amsterdam. It would be unfitting to conclude this brief note without heartily acknowledging the very great kindness shown to the members of the British Medical Association who took part in the conference by the Dutch physicians and surgeons, who spared no pains to promote the comfort of their visitors and provide for their entertainment. To M. Callach, the President, and to the Committee of the World's Exhibition, as well as to Professor Snellen, Dr. Pijnappel, the indefatigable Secretary, and the members of the Committee of the Conference a special meed of thanks is gratefully accorded.

MEDICAL PRACTITIONERS, REGISTRARS, AND CORONERS.

A REGISTERED medical practitioner, who feels aggrieved because a registrar of births and deaths frequently refers to the coroner cases in which the cause of death has been duly certified, asks whether there is anyone in authority over the registrar to whom a complaint can be made. We have good reason to know that if a registered medical practitioner has any ground to complain of the manner in which medical certificates are dealt with by registrars such a complaint would receive immediate and careful consideration from the Registrar-General at Somerset House. We should, however, point out that the responsibility for deciding whether an inquest is necessary in any case rests entirely with the coroner, and that the decision of the coroner in any given case that an inquest is unnecessary affords no proof that a registrar exceeded his duty in reporting the case to that official. It is obviously desirable that too many rather than too few doubtful cases should be reported to the coroner; and it is therefore undesirable that a medical practitioner

should regard as a personal affront the reporting of a case to the coroner respecting which he has given a medical certificate. It is clear, moreover, that such an excess of zeal on the part of the registrar as is complained of by our correspondent would not justify a registered medical practitioner in refusing to give a medical certificate in a subsequent case in which such practitioner was in attendance during the last illness of a deceased person. The duty of furnishing these certificates is statutory and compulsory, and can therefore be enforced.

THE ISOLATION OF INFECTIOUS DISEASES IN LONDON.

MANY adverse comments have been made during the week in regard to the arrangements of the Metropolitan Asylums Board for the reception of patients suffering from scarlet fever. The facts of the case which have given rise to the discussion are sufficiently simple. A child attacked with scarlet fever was taken to the London Hospital on the night of September 9th, two days after the rash had appeared. The authorities at the London Hospital of course could not receive her, but sent at once for the ambulance to remove her to the Asylums Board Hospital. On the arrival of the ambulance, however, the nurse in charge said there was no bed vacant, and that the child would have to be taken home. This was accordingly done. Then came what appears to have been a misunderstanding. The parents waited, thinking that so soon as there was room the child would be fetched, whereas the Asylums Board officers took no further notice, waiting for renewed application. We have no doubt that this was quite in accordance with rule and precedence, and that the Asylums Board officials are quite free from blame according to the peculiarly limited view of their functions entertained at Norfolk House. It would appear from the official letter which has been published that if at the moment when application for admission is made no beds are available the case is at once refused, and that there is an end of the matter unless renewed application is made. This is a weak spot in the management of fever in the metropolis. There are splendid hospitals and a splendid ambulance service, but there is no proper selection of cases for removal, and apparently the only way to secure admission is to stand importunately at the telephone until a bed is empty. As a shining example of how to remove such cases of fever as it does remove with the greatest celerity, and to treat such cases as it does treat with the greatest perfection, the Asylum Board deserves great praise, but there is but small common-sense in its distribution of its favours. If it were true that the ambulance service did in fact clear out the cases as they arose, and so stopped the distribution of infection it would be something to be proud of, but to remove in hot haste trivial cases that have been ill for days, to the exclusion of others of far greater urgency, is of small service in restricting the spread of epidemics.

BERI-BERI IN LUNATIC ASYLUMS.

IN view of the outbreak of epidemic peripheral neuritis in the Richmond Lunatic Asylum, Dublin, and of a similar and more recent occurrence in an English asylum, Dr. Oswald Baker's experience of an epidemic of beri-beri in Rangoon may have some interest for our alienist readers. In his admirable reports, Dr. Baker informs us that the Rangoon Lunatic Asylum, which had been in existence for twenty-three years, had hitherto enjoyed immunity from this disease, although beri-beri may be said to be endemic in the district. Its presence in the asylum was recognised for the first time on October 4th last year. On that date three of the patients were found to be affected with extensive oedema of an undoubtedly beri-beric character, and on examining the rest of the inmates, some 250 to 260 in number, several others were found to be similarly affected,

though to a slighter extent. On October 14th, the number of cases having risen to 30, it was thought advisable to transfer 18 of the invalids to Moulmein. On October 24th a careful examination of every lunatic in the asylum was made, when it was found that out of the 233 patients remaining, 84, or 36 per cent., had more or less oedema. The disease continued epidemic till November 25th, and in this short space of time 211 of the lunatics became affected in various degrees. Seven of them died, and when Dr. Baker's report was written there were several about whose recovery there were still grave doubts. All the cases were of the "wet" or oedematous variety. Bad cases suffered from breathlessness and other signs of respiratory and circulatory embarrassment. Paretic conditions were not observed; nor was anaesthesia noticed, though, of course, such symptoms may very well be present in lunatics without attracting observation. In discussing the etiology of this disease Dr. Baker remarks: "Beri-beri, as already stated, is a specific malady, and, like other diseases of its class, cannot exist in the absence of its particular virus. But the presence of the germ alone is often insufficient to give rise to any of the symptoms of beri-beri. Under hygienic conditions the disease may remain latent for long periods, or the tendency to it may become altogether eradicated. Given, however, persons with debilitated constitutions or lowered vitality, resulting from insanitary surroundings, especially overcrowding and bad ventilation,"—and, we may add, damp and a high atmospheric temperature—"the potentiality of the beri-beri virus then makes itself manifest, and symptoms of the disease are produced. And it is under circumstances such as these that the development of beri-beri takes place, and epidemics of it are produced." These remarks we thoroughly endorse; we commend them to those responsible for the health of our overgrown, overcrowded asylums in England, in too many of which the constant presence of endemic dysentery is standing testimony to persistent grave hygienic defects. That ordinary insanitary conditions are not alone responsible for beri-beri, or that they are in every instance necessary for its development, however much they may favour its epidemic explosion, is evident from Dr. Baker's statements as to the condition in these respects of the Rangoon Asylum. The hygienic conditions were excellent, he says, and he concludes that the outbreak was the consequence of the prevalence of a widely distributed epidemic affecting the population of the entire district in which the asylum stands. In several cases in which removal was tried the results were not invariably encouraging, or such as might have been expected judging from the experience of this measure elsewhere. Considering the extensive character in a geographical sense of the epidemic in and about Rangoon, we question if the patients were really removed from the endemic area, and we would hesitate, on the strength of Dr. Baker's experience, to lose our faith in this valuable and proved measure. Dr. Baker reports very favourably on the effect of blood-letting in the attacks of dyspnoea which are so painful and so fatal a feature in beri-beri; he says he has seen it give great relief, and in several instances save life.

THE SANITATION OF HEALTH RESORTS.

On many occasions for many years past opportunities have been taken in these columns to direct public attention to the question of the sanitation of health resorts, and to insist that the sanitary authorities of such towns were under a peculiarly strong obligation to make the amplest use of the powers conferred upon them by the Public Health Acts. Too many instances have shown that necessary precautions are frequently neglected, until some epidemic outbreak has roused public indignation, with the consequence of bringing temporary ruin to the affected locality. We shall not be suspected of desiring to shield health resorts which are backward in their sanitary affairs, but at the same time the greatest discrimination should be exercised in making charges of the sort, and it is to be feared that the kind of

war dance which Mr. Russell Endean has been executing in the public press will not have the effect of strengthening the hands of sanitary reformers. *Non tui auxilio nec defensoribus istis!* we may well exclaim. The charges which he has made against Paignton, a seaside resort on the coast of Devon, appear to be incapable of proof, and the statistics published by the medical officer of health show that the number of deaths from zymotic disease has been during the last quinquennial period exceedingly small. An extensive outbreak of measles is quoted by Mr. Endean as a proof of the insanitary condition of Paignton, but this is a very speculative opinion, since there is little or no proof that the spread of measles—a disease which is intensely infectious at an early stage—is directly related to bad drainage or insanitary conditions of a similar nature. Mr. Endean's want of acquaintance with public health questions is further shown by the fact that he goes out of his way to make a shameful attack upon the honour of the medical profession. Founding himself upon a strained interpretation of a passage in Dr. Cleveland's Presidential Address to the Section of Ethics at the recent annual meeting of the British Medical Association—an interpretation which Dr. Cleveland has emphatically repudiated—Mr. Endean asserts that it is the opinion of medical men that improved sanitation is, in the interests of the medical profession, undesirable. The implication is clear, and a more outrageously false and unhistorical charge could not be made. The history of improved hygiene in this country is the history of the unselfish struggles of the medical profession for better public health laws and better administration of these laws when obtained. Scandalous imputations against an honourable profession, and rash assertion, for which public apology has subsequently to be tendered, only hinder the cause of public health reform.

LOURDES AND ITS MIRACLES.

No doubt it is distressing to believers in the miraculous to find flaws in the character of those for whose benefit great miracles have been performed; nevertheless, those whose faith is less robust will find a certain satisfaction in the news that the investigations of the law courts have brought one more example of that asserted intrusion of the occult in the affairs of life which goes by the name of a miracle down to the humbler and more sordid level of a fraud. With the phenomena of faith cure and the tricks of hypnotism before us it would be idle to deny to Lourdes a share in the efficacy of suggestion on the human mind. Cases, however, here and there crop up which are admittedly difficult to explain, and in regard to some of them people have been found who think it simpler to believe in a miracle than to accept as possible the double improbability involved in the explanations given by those who reject supernatural interference. It appears that a man named Delaney, who was once a hospital attendant, was admitted to the Salpêtrière Hospital many years ago, where his case was diagnosed by Charcot as one of incipient locomotor ataxy. In 1884 he entered Dr. Callard's ward at the Hôtel Dieu. In 1886 he was at the Necker Hospital, where Dr. Rigal applied the actual cautery to the spine. Later he came under the care of Dr. Bull, in whose ward he stayed a whole year. He left the hospital apparently cured, but subsequently returned, and was afterwards in several other hospitals in Paris, and on several occasions underwent the treatment by suspension, having been hung up fifty-eight times, it is said, in the course of two months, which we venture to think is an exaggeration, and only another example of the sympathy-seeking devices to which this neurotic subject continually had recourse throughout his strange career. At length he went to Lourdes, where among his other adventures he came under the notice of M. Zola, who mentions him as being, to him, an inexplicable case. He arrived at Lourdes in the most pitiable con-

dition, and was carried to the grotto, where suddenly he had an extraordinary feeling of an inner force that impelled him to drop the crutch by the aid of which he had before hardly been able to crawl and to stand unsupported and walk. The next day he was medically examined in the presence of persons whose veracity and good faith are beyond question, and found to be cured of his ataxy, and on returning to the Charité Hospital in Paris the chaplain telegraphed to the fathers at Lourdes: "Doctors here staggered by cure of Delanoy. Have seen him four times this week. Walks like a country postman." Now here was a good miracle. There was no doubt that, so far as the ataxy was concerned, the man was well, and to explain the cure the non-believer in miracles had to form two extremely improbable hypotheses. First it had to be admitted that, for no very apparent object, a man should sham a disease, and persist for years in his deception, notwithstanding that it led to his having to undergo treatment of the most disagreeable character. Next the confession had to be made that all these eminent medical men had been mistaken; and although to some that may seem quite in the natural order of events, to others it seemed extremely unlikely. Now for the sequel. The miracle was made an overseer of a home for invalids awaiting the cure at Lourdes, but in 1891 he decamped after robbing the fathers of 400 francs. He then returned to Paris, and again took up his career of malingering, being admitted to Saint Anne's Asylum as suffering from persecution mania. Six months later he was there again for a few months, being certified as suffering from mental debility, but left after stealing 1,800 francs from the hospital pharmacy. In May, 1894, he was arrested by the police, when he endeavoured to play the part of one suffering from paralysis and insanity. He was, however, declared by the medical men who examined him to be malingering, and being found guilty was sentenced to four years' imprisonment and ten years' police surveillance. Now, we would be far from crying "*ex uno disces omnes*." The human mind is far too great a tangle, and the spurs to action in different men are far too varied for us to suggest that these phenomena can be explained so simply. But when we find a case which had been for so long regarded as inexplicable explaining itself in such a very simple way, it is worth while drawing attention to the importance of not calling Heaven to witness as to the miraculous nature of "inexplicable" phenomena just because we cannot explain them without accepting hypothesis repugnant to "common sense."

INDIVIDUAL LIBERTY AND SOCIAL DEGRADATION.

There are many optimistic people who profess to think that we are much over-ridden with laws and sanitary regulations, and that, in view of the general progress of the race, legislation might well hold its hand, and leave the future of mankind to the beneficent guidance of individual effort. Such people must often receive uncomfortable shocks when they rub shoulders with the disparity of actual life. The evidence given at a recent inquest at Croydon, for example, shows well the tendencies of unruled, unregulated, natural man, and proves that however greatly we endeavour to elevate the normal standard of living among the masses, there is always present a substratum of humanity so indifferent to decency and ordinary comfort as to be amenable only to the firm administration of sanitary law. It appeared that a man, having obtained permission to place his furniture, such as it was, in an unused stable, took up his abode there with his wife and children, and was ultimately joined by another family, so that in a stable measuring little more than 14 feet by 18 feet there were living four adults and thirteen children. There were two beds occupied by the two couples, and the remainder of the population appear to have slept upon the straw or in the mangers. In this predicament one of the women was confined of twins, and though the doctor urged her to go to the infirmary she persistently declined, saying that it was all right in the stable, as the

rain did not come in. At first she did well, but on the tenth day she went out and returned very wet and very drunk, after which she became so ill that she had to be removed to the infirmary, where she died. It is not a pleasant story, and does but illustrate the necessity for the rigid enforcement of sanitary law on the very poor, and the constant inspection of their dwellings by sanitary officials. For the fact has to be faced that the tendency of the lowest stratum in our towns is not upwards, and that one of the first directions in which the pinch of poverty shows its degrading influence is by producing indifference to overcrowding and carelessness about the decencies of home. These are matters that affect others besides themselves, for fever nests are thus developed. While then the community offers help, may be by charity, may be by the Poor-law, to those who are in poverty, the community may justly exact some return by enforcing submission to sanitary law.

ENZOOTIC DISEASES AMONG COWS AND MARES.

In an article appearing in a recent number of the *Journal of Comparative Pathology*, Professor Penberthy draws attention to the above subject. In Great Britain, in common with many other countries in which horse and cattle breeding is extensively carried on, a plague-like form of abortion causes serious losses. The affection amongst cows has been recognised for many years, but appears of late to be on the increase. On appearing in a herd, it frequently happens that 95 per cent. of the cows abort. Usually this condition of affairs obtains for two or three years, but, as a rule, after this period the cases of abortion become fewer, and in a year or two spontaneously cease. This, however, it is pointed out, largely depends on whether or not new animals for breeding are imported into affected herds. Expulsion of the fetus occurs at all periods of gestation, and evidence of putrefactive change in the abortion is by no means constant. The health of the cow is rarely appreciably affected, fresh conception is however often delayed, and when this occurs gestation is usually interrupted in the early stages. Though the most widely varying opinions have been expressed as to the cause of these abortions from the earliest records, it is gathered that the view of contagion has been held by some stock owners. Some narrated experiments by M. Nocard on the identical or a similar affection occurring in France give support to the view that it is a contagious disease and that the contagium enters by the external genital passages. Though the details of M. Nocard's experiments have not been corroborated, the writer of the article adduces as evidence in favour of a contagious nature the results of experimental cases, the fact that he has traced the affection to the introduction into previously healthy herds of cows from affected herds, and the favourable results of disinfectant treatment in cutting short outbreaks of the malady. Particular attention is drawn to the disastrous effects on some of our most valuable breeding studs. So serious has become the affection amongst cows that the Minister of Agriculture has been asked to include it in the Contagious Diseases (Animals) Act; while the Royal Agricultural Society has appointed a special committee to inquire into its nature and the best way of dealing with it. Professor Penberthy, referring to the maintenance and spread of the malady, attributes the greatest danger to the introduction of cows and mares, particularly animals which have aborted, from herds and studs in which the affection exists, the introduction of healthy pregnant animals into herds or studs where abortion is obtaining, and a disregard for thorough disinfection.

One of the strongest proposals for legislation which has been made for some time is to be discussed at the annual congress of the German Social Democratic party, to be held at Breslau next month. It is that the State should prohibit wet nurses. The reason assigned for the proposal is hardly less strange—the advantages attending the use of sterilised milk!

REPORTS

ON

THE NURSING AND ADMINISTRATION OF IRISH WORKHOUSES AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

I.—SOUTH DUBLIN UNION.

As the city of Dublin is divided by the river into north and south portions, it has two unions corresponding to these divisions; that in the south being the larger, and regarded by the authorities as somewhat of a model to other unions. The group of buildings stands on the outskirts of the city, on the road to Inchicore; they are clustered round an old Foundling House, which, with the old Houses of Industry scattered over the country, were taken over by the Poor Law Commissioners when, in 1840, the Poor Law was introduced into the country. The blocks of varying size and character, are built of grey stone, which gives a prison-like aspect to the exterior, and the whole forms a large establishment capable of accommodating 3,000 or more inmates; these include able-bodied, infirm, sick, lunatics (that is, feeble-minded and idiots), and children. The government of the establishment is in the hands of the master and matron.

THE SICK DEPARTMENT

is divided into "Catholic" and "Protestant" Hospitals, and there is a separate hospital for the children. The Roman Catholic patients are nursed by the nuns (Sisters of Mercy) and the Protestant by deaconesses, some of whom have been trained in the Tottenham Hospital, and formed part of the body under Dr. Lazoron. The nuns are untrained as nurses; they also nurse in the Children's Hospital.

The hospitals are supervised by a resident medical officer, who has 1,000 or more patients under his care, and there are three visiting doctors, each of whom has charge of one department. The matron who, in the absence of the master, kindly accompanied us round the building, gave us every facility for inspection, and all the information in her power. The wards gave us the impression of being

OVERCROWDED.

an impression which a closer view confirmed. They are long, narrow rooms, not lofty, and as the windows are small, and not carried up to the cornice, the ventilation is imperfect; the beds are placed side by side, with only enough space between them to stand in, and that amount of space is not always possible; in some of the wards the rafters are unceiled, and on the top always the roofs are pitched. The walls have a smooth surface painted in two colours. As these wards are occupied by the patients without the relief of a day room, and as in winter they would be more crowded, with less ventilation than on a summer day, and with more artificial light, we felt convinced that the cubic allowance was insufficient. The ground plan of the hospitals forms three sides of a square, the Protestant Hospital taking one side, with the male patients on the top floor and the females on the two lower floors. The Children's Hospital stands adjacent and accommodates over 100 patients; among these are the delicate children, and those who are unfit for school life.

THE PATIENTS

are classified as medical, surgical, and phthisical. Besides these a few female lock patients are kept apart and retained under treatment, because they have children, but the bulk of these cases are sent to the Government Lock Hospital. Mild cases of epilepsy are treated in these wards; simple idiots are also brought into the wards for treatment. A small bed card was over each bed; it was the regulation card, giving no clinical information. We noticed also a few temperature charts. The class of cases are such as would be found in any general hospital; indeed, there could be no difference except that there were more cases of hopeless paralysis and senility.

We were glad to see that these sad cases were being nursed in the general wards. The wards were fuller than usual; the medical officer, Mr. MacNamara, mentioned that many of the general hospitals had some of their wards closed for cleaning. The special wards for phthisis (this disease being very prevalent and fatal in Ireland) are kept at a higher temperature; we noticed several patients in advanced stages of the complaint.

Each patient was supplied with a small high table between the beds for food; there was a long table down the middle of the ward with benches, a few arm-chairs and ordinary chairs; a few commodes and lockers completed the furniture. The bedsteads are mostly of iron, with wire-mesh and hair mattresses for special patients; otherwise cocoa fibre and straw is in use, and the matron informed us that some wood-wool shavings had been sent for trial in the ticks. We did not observe that any of the beds were provided with pulls. This is a great omission, especially in a workhouse hospital where so many of the patients are helpless, and where the assistance is so scanty.

THE NURSING

in the part under the nuns is carried on under the triple disadvantage of being done by an untrained staff, of the nursing of the male patients being confined to supervision only, and of the night nursing being in the hands of a different staff. We noticed at once the difference between the work of the trained and untrained nurses, though the nuns brought system and order into their wards, their work was just lacking in that attention to details of nursing which can only be learnt in a hospital. Pauper help is very largely used in nursing the sick; the supply of nuns or of deaconesses is about one to each large ward containing from 45 to 50 beds, or to a group of smaller wards, so that too much reliance is placed on the inmates, or "deputies" as they are called. These paupers receive extra rations, and have some privileges, besides such bribes in kind or money as they may receive from the patients. On the female side most of the deputies are women of indifferent character, retained in the house because of their children; on the male side we noticed some able-bodied deputies who ought to have been earning their living outside, and off the rates. We omitted to mention that there is a wardmaster—an officer responsible for the control of the ward under the nuns.

At night there is one nurse for the male side and one for the female side, assisted by a staff of deputies, one or more of whom sit up in each ward. By this arrangement a large and important hospital is practically nursed by paupers, especially at night.

The patients in the separation ward appeared to be looking after themselves, or at best were in charge of an inmate. It is hard to conceive a more dismal hole than that in which we found these cases—a small, dark ward, crowded with women and children of a very low type, dirty and untidy in their persons and clothing, the unfortunate infants uncared for except by their mothers; the whitewashed walls, dirty floor, and pitched roof, small windows, low wooden frames, and straw beds, presented a picture of official neglect which we shall not soon forget. The door is locked on these inmates from 7 p.m., and they are left to get through the night with such decency and cleanliness as can be obtained by the use of pails, etc., and under no vestige of control.

THE CHILDREN'S HOSPITAL

is a bright and cheerful spot among these dreary surroundings; the wards are large, walls painted in two colours, coats down the middle, and small bedsteads round the walls, with toys, pictures, and plants giving it a pleasant appearance. The boys' and girls' wards duplicate each other on the ground floor. There is also a good playground, but no dayroom to relieve the wards in bad weather. The children are treated here until the age of 14 or 15. The hospital is nursed by the nuns and the inmates. The cases include every variety—the chronic hip joint, or spinal case, with cases requiring active surgical treatment, or of acute medical diseases; some convalescents were running about.

THE NURSERY

for healthy infants under 2 years occupies two floors, that for the day being on the ground floor, and above is the room

where the mothers sleep with their infants. In the day nursery there was a large number of babies, some in wooden cradles or being nursed by their mothers. The cradles are filled with straw, covered by a sheet and blanket; some of the cots that we looked into had wet sheets and straw; in some the food had been upset and not cleansed; many of the infants were untidy and ill cared for, the whole nursery showing want of control and supervision. The atmosphere, in spite of cross ventilation, was very close; there was no sense of freshness, but a very powerful odour of uncleanness. There is an officer over the nursery, but she is much handicapped in her work by the ignorant mothers, who are very difficult to manage. The lavatory and bath room attached to this department was littered and untidy, and anything but wholesome.

Besides these two departments for children, there is a probationary ward for the detention of fresh admissions without their parents for ten or more days at the discretion of the medical officer before they are sent into the schools.

THE AGED AND INFIRM,

as is the case in all Irish workhouses, form a separate class, and are located in blocks quite away from the hospitals. That for women was one of the best parts of the house; they are in small huts which run three sides round a garden where are seats, flowers, and grass, all of easy access from the wards. The wards themselves had a bright, home-like appearance, the cross-lights and the distance from the high buildings allowing of plenty of sunshine. The old men are not so well placed; they are in one of the stone blocks, their wards are dark and low-pitched, are crowded, and altogether are destitute of the comfort that one looks for for the aged.

Here we were introduced to the "harrow" bed, which is quite a feature in an Irish workhouse; it consists of five parallel wooden bars supported at the foot on an iron cross-bar and two iron legs, and at the head it rests on a continuous rail fixed on iron uprights about 6 inches from the wall, or, failing the rail, its place is taken by two legs; there is no bed head, the tick and pillows resting against the wall, and there are no sides. The bed is 2 feet 3 inches wide, stands about a foot from the ground, and on this is placed the straw tick. A variation of this bed is two low trestles, supporting two or three planks (see illustration.)

These old people are under the care of inmates, themselves only one remove from the stage of infirmity; no one is supposed to be in these wards who requires any help during the night, and that is as well, taking into consideration that the infirm are locked in their wards at 7 P.M., with only such assistance as they can render each other; and also that the only sanitary appliances are the commodes or pails in the wards. We did not notice anything but benches for the old men, either in their day room or wards.

THE LUNACY WARDS

are beyond these blocks, and separated from them by locked gates. The wards are large, but very full, the beds being placed in double rows back to back down the middle of the ward, as well as down the sides, an arrangement that appeared to us to be an unusual one for that class of patient. Some of the more helpless cases were in crib or box beds filled with straw; the wards were distinctly overcrowded, for the ceiling was low-pitched and the windows small. Several of the inmates were in the court, but many were in bed. One recent admission, the victim of puerperal mania, was dis-

Infirm Ward, Coochill Workhouse, showing the "harrow" bed.

turbing the whole ward by her cries, and arousing some of the patients to restlessness; this patient was restrained in bed by the usual lunatic's nightgown, and the matron was going to put on extra pauper assistants for the night. We were informed that there is no padded room, as violent cases are sent at once to the asylum; but in this case, the attack being recent, the doctor wished not to send the woman to the asylum. There is a great want all through the various departments of small wards for isolation. These wards are under the charge of officers, but they are not trained in lunacy work, and the number of patients under their care, amounting sometimes to 60 or more, makes it quite impossible for the attendants with only the help of the deputies to do more than keep these unfortunates in their places; indeed, it appeared to us that neither in their accommodation nor treatment was much done for these unhappy patients. The male lunatics are similarly circumstanced, if possible more crowded.

THE MATERNITY BLOCK

is near the gate, and is a small self-contained house, accommodating 40 beds in four wards. On the ground floor there are two wards for the labour cases; the wards are used indiscriminately, there being no separate room for the confinement, and above are the wards for pregnant women. There is no day room. The walls are whitewashed, and there is a want of light, the block being overshadowed by taller buildings. The number of confinements varies from 80 to 100 per annum. The women are attended by a midwife, who at the time of our visit was incapacitated from duty by a poisoned hand; her place was taken by a midwife from outside. Here also there is no small ward for the isolation of an infected case, which, considering the large number who pass through the wards, must sometimes present itself.

We were surprised to learn that there are no sanitary appliances in this block. The matron showed us a privy at some little distance, to which everything has to be carried. There is no bath room, slop-sink, or any of these adjuncts to nursing; and as there appeared to be structural space for the addition of these offices, we are at a loss to discover the cause of their absence.

HEATING AND VENTILATION.

The wards are heated by open fireplaces; many of them are old-fashioned and wasteful of heat and coals. In the winter there are besides steam-pipes running round the skirting of the wards; these pipes are of very large diameter. The windows throughout the buildings are small, set in heavy frames, and they do not reach the cornice. Sometimes they open on a pivot, and otherwise the upper half of the sash falls inwards, on a toothed bar; as the frames are heavy, these are awkward to manage. Gas is used throughout the workhouse.

THE SANITARY SYSTEM

is in course of alteration, many new closets are being added to the wards, and additional bath rooms with hot and cold supply are being fixed; these will be a great improvement. The new closets are fitted in the modern style with the flush, and they are on the landings near the wards; this situation appeared to us too near to be sanitary, as the space did not admit of an intercepting lobby. There are some closets outside the main wards that are flushed automatically. We were informed that the cloisters discharge itself every four hours, but, whatever may be the interval, it is evidently insufficient, as the trough was full of filth, and the fittings, floor, etc., were in a dirty state. There also appeared to be a deficiency in the arrangements for the disposal of foul clothing, as we came across a soiled tick hung over the railing outside a ward, making the air quite insupportable; we were informed that it was on its way to the laundry.

THE LAUNDRIES AND KITCHENS

are attached to each hospital, and are under the control of the officers; some of them were well appointed kitchens, with suitable appliances for expeditious and economical cooking. There are, besides, the main kitchen and laundry for general service. This union kills its own meat; we saw the victims in a paddock close to the building awaiting their turn of execution. The bread also is baked in the house. The sick diet is in the hands of the medical staff; the children are largely fed on eggs and milk. The inmates were assembling

for dinner at 2 o'clock; this is surely a long interval for the old and young, the breakfast hour being 8 o'clock.

RECOMMENDATIONS.

The impression that we carried away was that there are too many departments crowded into the space, and that it was quite impossible for efficient control to be exercised over such a heterogeneous establishment. The hospitals alone outnumbered several of the general hospitals in the city, for whose government a far more generous staff is considered necessary. It is a counsel of perfection to suggest the removal of the sick to more modern quarters and sanitary surroundings on the outskirts of the city, but that would be the most satisfactory solution of the difficulty, and such a move is bound to come in time. The staff in attendance on the sick is quite inadequate—13 nuns and less than half that number of deaconesses for the nursing by night and day of 1,000 sick, for the "deputies" cannot be reckoned on the nursing staff; and then we must take into consideration that the nuns are untrained. We yield to none in our admiration for the devotion of these religious ladies to their work, for the order and system that they have introduced into the wards, and for the care with which they minister to the poor committed to their care; if only to these qualities they could add the hospital training their efficiency would be increased, but as it is, too much of the nursing is in the hands of the "deputies." This union should take its place as one of the large training schools for the workhouse nurses, but until the entire staff is trained and until the deputies are swept away this cannot be done. We would also suggest that the attendants in the lunacy wards should be trained in the asylum, and that their number be increased; that attendants be provided for the infirm wards, whose quarters should be placed close to these wards, for assistance at night in case of emergency; and that the nursery officer should have better assistants; that the infants be placed under her entire charge, the mothers only having access to their infants at stated times. We fear encountering the wrath of the Board as it reads our suggestions, but they are made with an earnest desire to place before the guardians the impressions that we carried away, and we do not hesitate to say, from long experience in these matters, that, after the first outlay, the work would be done with greater economy and efficiency, and the South Dublin Union would take the position that belongs to it of right—that of the pioneer in the matter of workhouse reform.

VACCINATION AND SMALL-POX AT BRISTOL IN 1893-94.

XXI.

Dr. D. S. DAVIES, the health officer of Bristol, and his two assistants, have now issued their conjoint report on the epidemic of small-pox that visited the city in parts of 1893-94, and very interesting and instructive reading it is. The report deals first with the history of the disease in earlier times in Bristol, but space does not allow of our touching this portion; and then it proceeds to relate the difficulties as to hospital accommodation, and the successive steps taken in regard of the matter, the result being that not a single claim for admission had to be refused. But at one particular period only one bed was vacant.

Dealing with 360 cases occurring in sequence in the epidemic, Dr. Davies states that the total deaths among these numbered 36, or just 10 per cent. Of this total, 258 were of once vaccinated persons, with 19 deaths, or 6.6 per cent.; 15 re-vaccinated, with 1 death, or 6.5 per cent.; and 41 unvaccinated persons, with 11 deaths, or 26.8 per cent. of cases. Of the remaining cases, 7 had had previous small-pox, none dying, and concerning the rest no reliable information as to vaccination was forthcoming.

In the first ten years of life there were 7 attacks in vaccinated children, all being mild, and no death occurring; and 23 in unvaccinated, 16 being severe, and 6, or 26.1 per cent., proving fatal. Thus vaccination at this age-period gave absolute protection against fatal attack. In the next quinquennia there were 25 vaccinated cases, 1 death, and 4 unvaccinated, none fatal. At ages 15 to 30 there were 160 vaccinated cases, 2 deaths, or 1.2 per cent.; and 10 unvaccinated,

with 2 deaths, or 20 per cent.; at greater ages 97 vaccinated cases, 16 deaths, or 16.5 per cent.; and 4 unvaccinated cases, 3 deaths, or 75 per cent. These data show the increasing tendency to attack and death in the vaccinated as age advances and the effects of the primary vaccination wear away; while the disproportionate fatality rate in the unvaccinated class is equally striking in the earlier years of life. Looking to the age periods of all cases, we find the per case rates of mortality were as follow:

	0 to 10.	10 to 15.	15 to 20.	20 and over.	All ages.
Vaccinated	0.0	4.9	2.7	18.4	6.6
Unvaccinated	25.1	0.0	20.0	75.0	30.8
All cases	25.0	3.4	3.3	26.4	10.0

The single death in a vaccinated child under 15 years of age is phenomenal in Dr. Davies's experience of 687 cases of the disease, among which 96 were in children under 15 years of age. In one instance he relates that a baby born while its mother was recovering from small-pox did not catch the disease, and was also proof against vaccination.

Treating of the data culled from study of invaded houses, Dr. Davies shows that in Bristol vaccination conveyed, when set against non-vaccination, a twenty-three fold immunity from attack and absolute immunity from death as against 11.5 per cent. fatal in the unvaccinated, at ages under 10 years, and a three-fold immunity from attack and a ten-fold immunity from death at ages over 10 years. Of 59 unvaccinated persons found in invaded houses, 23 were vaccinated on or before the fifth day of exposure to infection, and not one took small-pox in any degree; but of 32 persons remaining unvaccinated and exposed to infection, no fewer than 19 (59 per cent.) contracted small-pox. Of 468 persons thus exposed and successfully revaccinated only 8, in whom the disease had already begun to incubate, were attacked by small-pox, all recovering, and only 5 per cent. of other 859 exposed persons once vaccinated were attacked.

Of 62 persons on the hospital and ambulance staff, 3 contracted small-pox, namely, 1 primarily vaccinated only, 1 revaccinated fourteen years back, and 1 (fatally) who had been revaccinated twenty years back, the deceased being a hospital laundress who had on previous occurrences of small-pox also washed the clothing of patients without ill-effect. She was accidentally omitted from the list of those set down as requiring vaccination in the present epidemic.

There is other matter of interest in the report which, for considerations of space, we are reluctantly compelled to pass over.

THE INTERNATIONAL CONFERENCE ON RAILWAY AND MARINE HYGIENE.

[FROM OUR SPECIAL CORRESPONDENT.]

OPENING CEREMONIES.

THIS Conference, which took place in Amsterdam on September 20th and 21st, owes its origin to the initiative of the Committee of the "World's Exhibition" now being held in the Dutch capital to illustrate the progress of modern travelling facilities. Through the kindness of the promoters each member of the Conference received a free ticket of admission to the Exhibition, and at a reception held on the evening of September 19th the members were cordially welcomed by the Exhibition Committee, and conducted over the buildings.

PRESIDENT'S ADDRESS.

The special work of the Conference commenced on the morning of September 20th, when from forty to fifty gentlemen assembled in one of the salons attached to the Zoological Society's Gardens, under the presidency of Professor Snellen, the eminent ophthalmic surgeon of Utrecht, and consulting oculist to the Dutch State Railways. In his opening address, the President pointed to the fact that by the increase of travel for business or recreation, many questions of great hygienic importance to the public and the various traffic-conducting organisations had been raised. These demanded more attention than had yet been paid to them at the International Medical Congresses. Referring to the necessity for efficient eyesight in traffic conductors, he traced the development of the movement for seeing better control which originated with Wilson of Edinburgh in 1853, and was supported by Favre in France, Holmgren in Sweden,

by Cohen, and specially Donders in Holland, as well as Joy Jeffries in America, and he generously acknowledged the importance and the stimulating influence of the work done by the British Medical Association's Committee in recent years. With evident pleasure he quoted from the Appendix to the Committee's First Report (1892) the statement that the arrangements for the control of railway servants' eyesight are more complete in Holland than in any other country. This is undoubtedly the case. The examinations are entrusted to a limited number of competent medical men, the refraction is measured. Emmetropia and normal vision ($\frac{1}{2}$ Snellen) are required for the locomotive service, the colour sense is estimated qualitatively and quantitatively. Every man is re-examined at regular intervals, and all doubtful cases are referred to the consulting oculist for a special opinion.

OFFICIAL BUSINESS AND REPORTS.

After the presidential address, Dr. PRINAPPEL, as Secretary of the Organising Committee, gave some details of the preliminary work which had been done prior to the assembling of the Conference, not the least valuable part having been the preparation and distribution of a summary of the hygienic measures adopted in the Dutch railway and marine services.

The Organising Committee was then constituted the "Bureau définitif," and the following gentlemen were elected Vice-Presidents: Mr. Berry (Great Britain), Dr. Créquy (France), Dr. Zeitlmann (Germany), Dr. Wyruboff (Russia), Professor Nüßl (Belgium), Dr. Joy Jeffries (*in absentia*) (America), and M. Mahieu (Holland). In the programme of the Conference ten subjects were submitted for discussion.

EXAMINATION OF RAILWAY SERVANTS.

In the first place an expression of opinion was sought as to whether the examinations in sight and hearing and general fitness ought to be entrusted exclusively to medical men, and in conformity with fixed standards. Information as to the regulations existing in different countries was also requested.

Mr. BERRY (Edinburgh) made a brief statement of his views, and, while deprecating any alarmist attitude, thought that the examinations should be conducted by the ordinary railway surgeons.

Dr. GEORGE MACKAY (Edinburgh), Honorary Secretary of the British Medical Association's Committee for Promoting the Efficient Control of Railway Servants' and Mariners' Eyesight, presented a paper dealing with the present position of the Railway Servants' Eyesight Question in Great Britain and Ireland. He stated that since the publication of the Royal Society's and the British Medical Association's Committee's reports in 1892, a considerable improvement had taken place in the methods of examination employed by the railway companies in the United Kingdom. Most of the largest now entrust their eyesight examinations to medical men, but fully one-third of the railway servants are still accepted merely on the judgment of lay officials. The tests are not uniform. A few demand $V = \frac{1}{2}$ Snellen. Many use the Army dot test at 15 feet, which is equal to $\frac{1}{3} = \frac{1}{2}$ Snellen. Refraction is rarely estimated. Holmgren's wood test is now largely used for the colour sense, but there is little control over the competency of the examiners to apply it. Quantitative estimations are practically unknown. He submitted the recommendations published in 1892 by the two above mentioned Committees, and supported the proposition of the day in the affirmative.

Dr. CRÉQUY (Paris) thought it was more practical that the sight should be tested with models of the actual signals instead of letter type, and presented a set of the coloured test cards which are employed by the Compagnie du Chemin de Fer de l'Est.

Professor NÜSSL (Liege) lamented the insufficiency of control on the Belgian lines, and favoured an international standard.

Dr. LANTSCHERRE (Brussels) gave some striking personal experience of defective eyesight among Belgian railway servants and strongly supported the opinion that a thorough medical examination should be required of all candidates at the time of entrance.

EXAMEN'S EYESIGHT.

At the afternoon sitting Mr. BICKERTON (Liverpool) read a

communication on the History of Ships' Sidelights and Screening, the indifference with which the English Board of Trade have permitted colour-blind and defective-sighted men to enter the mercantile marine, and the utter neglect of the eyesight question in Board of Trade inquiries into shipping disasters, etc. Mr. Bickerton's paper dealt with some of the serious results which have followed from the Board of Trade's misguided efforts to control the eyesight of officers in the mercantile marine,¹ and he illustrated with diagrams the fresh danger which has arisen from the insufficient screening of the red and green sidelights recommended by the latest Board of Trade regulations.

On the second morning of the Conference a very interesting discussion was initiated by Dr. MAYWEG (Hagen) as to the extent to which spectacles are admissible for railway employees. In 1887 he advocated their use. In Baden, Saxony, and Bavaria they had been used without complaint; at one time in Prussia also, but not now. Dr. Mayweg thought that new applicants for service requiring spectacles to secure normal vision should not be accepted, but that men found to have refractive errors after admission to service should be allowed to wear glasses.

Professor SNELLEN said that it was the custom in Holland not to admit men with abnormal vision, but that if at re-examination spectacles were needed they were supplied by the company. Hitherto locomotive men had not been allowed to wear glasses, but he was at present trying them experimentally in a hypermetropic driver of long experience and exceptional trustworthiness.

Dr. LANTSCHERE objected to spectacles for men exposed to snow, rain, frost, smoke, oil, and dust; and was supported in that opinion by Professor McHARDY (London), who emphasised the difficulty of keeping not merely the front but the back of the glasses clean.

The general opinion seemed to be that glasses were not advisable for locomotive men, though permissible for other ranks.

THE MEASUREMENT OF ACUITY OF VISION.

In introducing the question of the best method of measuring acuteness of vision, an important communication was made by Professor SNELLEN. After passing in rapid review all the best known modes of form-vision testing, he discussed the merits and disadvantages of various type tests. He admitted that his own test-type letters were open to the objection that the letters in any row were not equally discernible through inherent difference of shape. Exactitude of expression had become very necessary, for cases had arisen (for example, in courts of law) where a very precise estimate of the visual power was of the gravest importance. For ordinary purposes he considered that his familiar **W**-shaped test figures were at once accurate and convenient, but that if any other types are to be employed their value should be stated in terms of three parallel lines of black, each subtending a visual angle of one minute at a given distance, and separated from one another by white interspaces of the same breadth.

QUANTITATIVE ESTIMATION OF THE COLOUR SENSE.

Professor SNELLEN also made an interesting communication on the various methods of estimating the colour sense quantitatively. He mentioned a modification of Donders's system which he had lately devised with the assistance of Professor Enthoven of Leyden, but admitted that a good method was still a desideratum.

ACOUSTIC SIGNALS AND ACUTENESS OF HEARING.

Another communication of considerable interest and practical importance was that presented by Dr. ZWAARDMAKER (Utrecht), on acoustic signals and acuteness of hearing, who, after supplying the results of an original inquiry into the hearing of a large number of railway men, urged that applicants for railway service should have at least one ear possessing normal acuteness for the whispered voice at one metre, and recommended that the test should not be limited to one tone, but applied over the whole chromatic scale of Bezold.

His contention was supported in an able speech by Professor GUYX (Amsterdam).

RAILWAY HYGIENE.

Papers dealing with the organisation of medical aid on railways were read by Dr. BLUM and CHÉQUY (Paris), Dr. DENTZ (Helmönd) and Dr. J. MENNO HUIZINGA (The Hague) described the excellent arrangements made under his directions by the Compagnie Néerlandaise-Américaine de Navigation for accommodating emigrants from the Hague.

Dr. G. WALLER (Amsterdam) gave a communication on Overwork and other Conditions which lead to the Invaliding of Railway Servants; Dr. BLUM contributed one on Traumatic Hysteria; and Dr. DOZY (Amsterdam) discussed the Disinfection of Stations, Restaurants, etc.

NEXT MEETING.

It was agreed to hold another Conference at Brussels in 1897, under the presidency of Professor Nüßl, with Dr. Lantscheere (Brussels) as Secretary.

INTERNATIONAL CONGRESS OF PHYSIOLOGISTS, BERNE, 1895.

Opening Ceremonies.—Goltz and Ewald on the Spinal Cord and the Functions of Defecation and Urination.—Langley on Sympathetic Areas.—Effects of Hypnotics on Cortical Cells.—The Physiology of Digestion.—Tigerstedt on Respiration.—Professor Kronecker's Garden Party.—The Physiology of the Circulation.—Cathedral Concert and Illumination.—Excursion to the Scheinige Platte.—Gamblee on Hemoglobin.—Cold Baths in Fever.—Banquet.—Mosso on Circulation and Respiration at High Altitudes.—Next Congress to be held at Cambridge.—Exhibition of Apparatus.

[FROM OUR SPECIAL CORRESPONDENT.]

ALL physiologists should rise early. In Berne they were true to their principles; the valley of the Aar was still misty when at 8 A.M. on Monday, September 9th, the physiologists began to collect in the magnificent new institute which after the great Berne professor is named the Hallerianum. A plaster relief of Ludwig, surrounded by a wreath of laurels, and a bust of Helmholtz served to remind the members of the Congress of the activity of the hand of death during the past year. A speech of welcome from Professor Kronecker (Berne) and the Swiss Minister of Education, and the election of Professors Bowditch and Chauveau as Presidents, opened the proceedings.

To those who were on the look out for facts of value to practical medicine or surgery, the most interesting paper of the morning would be that of Professors Goltz and Ewald, of Strassburg. These physiologists showed a dog all of whose spinal cord had been removed from the middle dorsal region downwards, including the cauda equina. The removal had been performed at three stages during one year and a-half, and the animal had survived the last operation two years. Its voluntary muscles below the line of the lesion had undergone complete degeneration; it however retained the power of perfectly normal defecation, and practically normal urination. The external sphincter ani was perfectly normal. The bitch since the last operation had given birth to young ones, and suckled them normally.

Upon this demonstration of Ewald's by an almost anatomical sequence followed that of Professor Langley on the functions of the sympathetic system. Professor Langley showed in a striking manner the erection of the hairs in skin areas, corresponding to the distribution of the sympathetic fibres stimulated.

Dr. Demoor (Brussels) showed the interesting fact that an actual anatomical change takes place in the processes of the cortical nerve cells in animals to whom a strong dose of morphine or chloral hydrate has been given.

In the afternoon the two papers of medical interest were those of Professor Herzen (Lausanne) and Professor Tigerstedt (Stockholm). Herzen showed a specimen of pure gastric juice collected by a fistula from the isolated stomach of the dog, which was capable of digesting its own weight of cooked protein; he further brought evidence to prove that the spleen exerts an important influence on pancreatic digestion. By comparing the digestive power of two pancreatic infusions to

¹ BRITISH MEDICAL JOURNAL, May 15th, 1896, p. 1112.

which the same quantity of ordinary arterial blood and blood from the splenic vein had been respectively added. Professor Tigerstedt described an apparatus for research on respiration in man. The point of the apparatus was that it was perfectly ventilated, and that the chamber was of sufficient size to allow the author to work on several men at the same time.

After a hard day's work an evening's pleasure did not come amiss, and nearly everybody availed themselves of Professor Kronecker's invitation to an evening garden party. Music, dancing, and a most excellent supper gave ample sources of enjoyment, and the delightful friendliness of the host and hostess gave a charm to the whole which it is seldom one's lot to experience.

Tuesday morning was devoted to the physiology of the circulation. Professors Hürtle and Mosso each showed a new apparatus for the determination of the blood pressure in man. In Hürtle's apparatus the arm, rendered bloodless by an Esmarch's bandage, was introduced into what was practically a phlethysmograph, and this was connected with a tambour, the movements of which were registered on a recording cylinder. In Mosso's apparatus two fingers of each hand were introduced into gloves, which were contained in a metal tube filled with water and closed except at one place, where it was connected with a mercurial manometer, on the distant limb of which a pen floated, and this wrote on a cylinder. In the tracing produced by each apparatus the individual pulsations as well as the respiratory curves were clearly reproduced. Professor Kronecker showed a most striking experiment on a dog's heart. He injected paraffin having a melting point of 39° C. into the descending coronary artery; the heart entered at once into a condition of fibrillary contraction, from which, according to Kronecker, it never, except in very young animals, recovers. The great sensitiveness of the structures which produce the rhythmic contraction of the heart to sudden anemia is greatly in favour of the view which regards them as being of the nature of ganglia.

Two papers of general interest were read in the afternoon, one by Dr. Dastre (Paris) which showed that strong neutral saline solutions will produce the same effects on fibrin as the gastric juice; and one by Professor Gotch (Oxford) on the nature of the discharge of certain electric fishes. On Tuesday evening the "congressists," on pleasure bent, met in the cathedral, where an excellent concert, in which the famous organ took an active part, was provided for them; afterwards, the tower of the cathedral was illuminated in their honour.

Wednesday was a whole holiday at the Congress, and an excursion was organised to the Scheinige Platte. Unfortunately the day was not a very fine one, and a good view of the Jungfrau was not obtained.

On Thursday morning M. Arthus (Paris) defended the view that the oxalates remove the coagulability of the blood by removing the calcium salts against the view of Alex. Schmidt, who holds that they have a specific action, and that calcium salts are not absolutely necessary to coagulation. M. Arthus was followed by Professor Gamgee, who gave the result of his researches on the violet and ultra-violet spectrum of hemoglobin and its derivatives. He showed that the broad absorption band produced by this substance, and situated between the lines G and H, was in reduced hemoglobin, in NO hemoglobin, and in CO hemoglobin, displaced to the less refrangible end of the spectrum. Dr. Jaquet (Basle) read a paper on the influence of cold baths on the circulation in fever. He showed that in fever the red blood cells disappear from the systemic veins and collect in the loin and abdominal veins, and that cold baths prevent this, while antipyrin does not. On Thursday evening a large banquet took place. During dinner speeches were made by Professors Kronecker, Kocher, Mosso, Hegir, Langley, Burdon Sanderson, Dastre, and Bowditch.

Friday was devoted to physiology and business. Professor Mosso read a paper on his researches on the respiration and circulation in man at high altitudes. These researches were made on Mount Rosa at a height of 5,600 metres. Mosso found that at this altitude during repose respiratory exchange is less, and this he regards as due mainly to two factors—a diminution in the tension of the carbonic acid in arterial blood, and the physical effect of low pressure on the nervous system.

The business proceedings of the Congress included an invitation from Professor Michael Foster, which was accepted, to hold the next congress at Cambridge.

An exhibition of physiological apparatus, in which mechanicians from nearly all the Continental laboratories took part, brought to a close a work which was most full both of pleasure and instruction.

BERI-BERI IN AUSTRALIA.

We have received a very interesting communication from Dr. Cyril Ernest Corlette on the subject of beri-beri in Sydney, N.S.W. We regret that the demands on our space preclude us from giving his paper *in extenso*, and that we must content ourselves with little more than recording the fact of the endemic existence of this important disease in our Australian Colonies.

Dr. Molloy, of the Melbourne Hospital, in the *Transactions* of the third session of the Intercolonial Medical Congress of Australia, 1892, asks the question, "Is beri-beri endemic in Melbourne?" He mentions that in March, 1888, nine Chinese were brought from a particular shop to the Alfred Hospital all of them suffering from symptoms of peripheral neuritis and oedema; and he further states that subsequently a series of similar cases cropped up in Melbourne.

Dr. Graham describes¹ a form of peripheral neuritis epidemic among the Chinese in Sydney, and Dr. R. T. Paton² who has seen beri-beri in its recognised haunts in the East, has concluded that these cases of peripheral neuritis are really of this nature. Some time ago³ we recorded the occurrence of an epidemic of this disease among some aboriginal Australians at Wyndham, East Kimberley, Western Australia. It is evident therefore that an endemic form of peripheral neuritis is extensively distributed in Australia, seeing that we have accounts of it from three widely separated points; and now Dr. Corlette's account, based on an experience of 60 cases, does away with any doubt that may have existed as to its true nature and significance. The symptoms, the progress of the disease, the mode of death, the pathological anatomy, and the hygienic conditions under which the cases develop distinctly point to beri-beri. Hitherto only Chinese and other Orientals have been attacked, and from this circumstance it might have been conjectured that the cases were imported, but on inquiry it is found that many of those attacked had been resident in the Colonies for years. Moreover, it was ascertained that the disease tended to occur in little epidemics, several cases coming from one house, a fact distinctly pointing to the existence of local endemic foci.

Dr. Corlette's description of the symptoms and pathological anatomy coincides in the main with the accepted descriptions of beri-beri. He points out one or two symptoms not alluded to by other writers, which, should the observation be confirmed, may prove of great use in diagnosis and differentiation. He says, "Patients suffering from this disease are very subject to attacks of sweating, most frequently confined to the head, face, and trunk, but sometimes general." In some instances it is profuse, in others more moderate, and it is not influenced by atmospheric temperature. He further says that he has almost constantly found two very acutely tender spots on the foot—one about the middle of the dorsal aspect of the first metatarsal space over the bifurcation of the internal branch of the anterior tibial nerve, the second on the outer side of the foot at the prominence of the cuboid corresponding to the external saphenous nerve. He believes that these tender points are peculiar to beri-beri.

It is difficult to say how long beri-beri has existed unrecognised in Australia—probably for many years. There is evidence of its presence there at least 15 years ago, although the true nature of the cases was unsuspected at the time; they appear in the hospital records as "ataxia," "rheumatism," and so forth. Although hitherto, so far as known, confined to Chinese, there can be little doubt that sooner or later Europeans will be attacked, and that we will hear of outbreaks of beri-beri in Australia.

¹ *Australasian Medical Gazette*, No. 116, November 1893, 1894.

² *Australasian Medical Gazette*, No. 156, November 1894, 1895.

³ *British Medical Journal*, October 27th, 1894.

gaols, poorhouses, lunatic asylums, and similar institutions. In future the possibility of the case being of this nature must be borne in mind by the Australian practitioner when he approaches the diagnosis of peripheral neuritis.

Dr. Corlette's remarks on treatment are judicious; he very properly dwells on the paramount importance of removal of the patient from the endemic locality. He says nothing, however, about the employment of bleeding, nitrite of amyl or nitroglycerine and purgatives, measures which have been found of service elsewhere in relieving the attacks of orthopnea from overdistended right heart, so common and so dangerous an occurrence in bad cases of beri-beri.

The sanitary authorities in Australian towns will doubtless take note of the appearance of beri-beri in the colonies, and institute measures calculated to improve the hygienic conditions under which their fellow Chinese colonists elect to live.

THE RETIREMENT OF PROFESSORS.

THE report of the Committee appointed by the Treasury to consider the question of the desirability of a fixed age for the compulsory retirement of professors serving under the Crown has been published as a Parliamentary paper. The Committee consisted of Lord Playfair, Lord Welby, and Sir M. W. Ridley, M.P.; Mr. C. L. Davies was secretary. The report, which was addressed to the Lords Commissioners of Her Majesty's Treasury, was in the following terms: The Commissioners have taken the evidence of presidents and professors of the Queen's Colleges in relation to their retirement upon superannuation at fixed ages, as determined by the Order in Council of August 15th, 1890. They were of opinion that the Commission of 1888, upon the report of which to some extent that Order in Council was based, did not intend that the limitations of age applied to Civil servants generally should be deemed applicable to presidents and professors of colleges who are appointed and serve under different conditions from those which prevail in the Civil Service. These presidents and professors were appointed at a maturer age, and have, by the nature of their employment at seats of learning, less tendency than civil servants to become inefficient at the age of 65. Indeed, up to that age it was often found that their efficiency increased by experience in teaching as their age progressed, though undoubtedly a time does arrive when advancing age weakens the receptivity of the professor to new discoveries in science, and diminishes the inclination to alter his instruction in order to adapt it to these changes. When this occurs the students are the sufferers. In the German Universities this well-known degeneration of intellectual activity among the aged is partly compensated by the appointment of active young "extraordinary professors," who, though not on the ordinary staff of the colleges, are allowed to give competing lectures within their walls.

In Edinburgh an extramural competition is encouraged, and in each Scotch University, when professors show diminished efficiency through age, it is the duty of the University Court to superannuate the professor under a pension scheme, which is charged upon a fixed Parliamentary vote for all the Scotch universities.

The Queen's Colleges in Ireland are in a different position, for they are only to a small extent dependent upon votes in Parliament, being mainly supported out of the Consolidated Fund. They are in consequence of this peculiarity in more intimate connection with the executive Government, with which the presidents are in frequent communication as to the working of the college and the efficiency of the professors, who are appointed by the Crown and can be dismissed by the Crown.

The statutes which govern the colleges also emanate from the Crown, and are not like those of other colleges, the product of academic autonomy. Under these circumstances the Commission are of opinion that there should be fixed rules as to superannuation of presidents and professors, and that they should be made by college statutes and not by an Order in Council. They are of opinion that when a professor reaches 65 years of age the president of the college should be bound to report to the Government the condition of efficiency of the teaching. If these are, and continue to be, satisfactory, the professor need not be superannuated till 70, but at this age his re-

tirements should be absolute. In regard to presidents, they are of opinion that the age of 70 should be the period of retirement, but should the visitors of the college formally report that the college would suffer by the loss of the experience which the president has acquired, they think that the treasurer and not the Irish Office, should have power to continue him as president for a certain number of years, not exceeding five, so that at the age of 75 the retirement of the professor should be absolute. They are quite aware that there are cases where professors at 70, and presidents at 75, are fully competent to discharge their duties, but the advantages derived from superannuation would be seriously diminished if to meet these rare cases there were uncertainty in regard to the application of a general rule. They have observed with regret that the alumni of the Queen's colleges do not seek to go back to them as professors, and it was explained to them that one reason for this was that it was useless for them to prepare for a professorial career in these colleges while so much uncertainty prevails as to when the chair would become vacant. They also took the evidence of Professors Lockyer and Rucker as to the conditions which prevail in the Government School of Science in South Kensington, and they found that the age of 70 for professors was considered a proper age for retirement under ordinary circumstances. In their opinion, as the professors are not appointed till middle life, the addition of seven years to their period of service in calculating the amount of their superannuation obviously tends to secure eminent specialists as candidates for office. The power of voluntary retirement at the age of 60 has also much to commend it in this sense.

The report is followed by the minutes of evidence taken on June 17th, 18th, and 19th, during which nine witnesses were examined.

THE TITLE OF PHYSICIAN.

WHO IS A PHYSICIAN, AND WHO HAS THE RIGHT TO CALL HIMSELF BY THAT TITLE?

THIS is a question to which some time ago the medical profession and the public would have given the same answer, but now it is evident that a large section of the medical profession is desirous of extending to the title a meaning which outside the profession is either not recognised, or at any rate very imperfectly understood.

We are not for a moment contending that the way in which the public regard the title of Physician can in the slightest degree affect the legal aspect of the question, and we admit that the courts of law in dealing with that question may have regarded it from a too academic point of view.

But we have yet to learn that the Fellows and Licentiate Members of the Royal College of Physicians of London regard those Licentiates to whom there has been granted a diploma to practise medicine, surgery, and midwifery, and who are allowed to compound and dispense medicine for patients under their own care and to practise in partnership, as equally entitled to call themselves Physicians with the Fellows and Licentiate Members of the College.

It certainly appears that beyond the fact that such Licentiates receive their diploma from the Royal College of Physicians there is nothing as regards their legal status to imply that they stand in a different position than the Licentiates of the Society of Apothecaries as to whom Lord Coleridge and Mr. Justice Wright in their observations in the case of *Regina v. Baker* expressed an opinion adverse to their right to call themselves Physicians. The question at issue is still further complicated by the fact that the Licentiates of the Royal College of Physicians of Ireland are by the terms of their diploma styled Physicians, and, if they are so styled, it seems an anomaly that Licentiates of the Royal College of Physicians of England, who are not Members or Fellows of the College, should be in any worse position. What effect this circumstance, if it had been brought to the knowledge of Lord Coleridge and Mr. Justice Wright, would have had we do not know, but, so far as our opinion is of any value, we doubt whether a Licentiate of the Society of Apothecaries or a Licentiate of the Royal College of Physicians of London at the present moment could be successfully proceeded against for assuming the title of Physician. At the same time, if our view of the legal position is correct, it follows that the

title of Physician will cease to have the special value it formerly possessed. This may be a matter of comparatively little importance, but it is the logical consequence which flows from the wish that the distinction between the pure physician and the general practitioner should no longer be accentuated as heretofore.

THE BARBER-SURGEONS' HOLBEIN.

A short time ago we called attention to the endeavour which was being made to purchase the Holbein, now in the possession of the Barbers' Company, for the purpose of placing it in one of the public galleries, where it would be safe from fire. The urgent necessity of ensuring its safety has again been emphasised by the large fire which occurred in Monkwell Street, within two doors of the Barbers' Hall. The conflagration was fortunately kept within bounds on this occasion, but the great city fires spread with such tremendous rapidity that it is often impossible to arrest their course.

Sir J. C. Robinson, Her Majesty's Surveyor of Pictures, in an interesting letter to the *Times*, suggests that the same precautions should be adopted in regard to the Holbein as have already been adopted for the Montagna cartoons at Hampton Court. He claims that by his system great pictures can be detached from the walls and can be taken bodily out of a building and placed in safety in the course of a very few minutes. He thinks that the position of the Holbein upon the ground floor of the Barbers' Hall would render this removal easier than in the case of the Hampton Court cartoons, which are upon the first floor. These are so awkwardly placed that it has been necessary to cut a slit in the floor, through which the pictures, whose frames are on wheels, can be lowered. It should be remembered, however, that the Holbein is placed in a particularly unfortunate position, for the forecourt of the Barbers' Hall is surrounded by high buildings and is approached by a narrow gateway, which would probably become impassable at a very early period in case of fire. Monkwell Street, too, is very narrow and the turnings out of it are rectangular.

Sir J. C. Robinson has examined the picture with the experience of an expert, and he says that it "cannot be taken as a masterpiece of the great German painter. All indications seem to point to the fact that it was originally a somewhat hasty conventional performance, its composition and arrangement being dictated by the worthy citizens, not specially enlightened in matters of art, who commissioned the work, and that it was left unfinished at the death of the painter from the plague in 1543. Furthermore, that at a subsequent period a very inferior hand or hands completed the picture in a perfunctory manner."

"The changes induced by time and by injudicious treatment from century to century under the pretence of 'restoration' have resulted in further deterioration, rendering it difficult on any casual and cursory examination to decide on the manner and measure in which Holbein's original work has been distorted and defaced."

"The principal conclusion to which my recent examination has led me is that when the hand of Holbein was paralyzed by death, it had nevertheless worked more or less over every part of the great panel—very elaborately and minutely in some parts, and very slightly in others; but that nowhere had the finishing touches and work required to give final truth and perfection of representation been bestowed. Nevertheless, had the picture remained in the condition in which it was left at the death of the painter, it would have been of infinitely greater value than at present. We should then have had invaluable insight into the great painter's technique and mode of procedure, and the truth to Nature and suggestive excellence of every unfinished line or vaguely impressed tint would probably have had a charm for us scarcely less potent than would have resulted from months or years even of patient elaboration by the artist himself."

"This, however, was not to be. It was decreed that fools should rush where angels might have feared to tread. Cunning and mighty indeed should have been the hand which dared to lay a touch on Hans Holbein's work; but, as it happened, it was those of countless duffers of a low type. I think it most likely that an interval of some twenty

1 BRITISH MEDICAL JOURNAL, 1895, 1, p. 1450.

or thirty years elapsed before the Barber-Surgeons, in an inauspicious moment, determined on the completion of their picture. For the style of execution—if style it can be called—of the superadded work seems to be that of a somewhat rather advanced Elizabethan period. Probably the worthy guildsmen thought it unseemly that the lineaments of some of their number should stand out conspicuously in the corporate picture whilst those of others were seen as mere ghostly shadows, and it would seem that when the principal range of figures received the finishing touches from the post-Holbein improver there was still a relay of entirely unrepresented claimants, for the upper row of portraits on the right of the picture were obviously painted at a still later period, and by an even weaker hand. These last are so entirely devoid of artistic merit and are so awkwardly placed in the composition that they were probably not even indicated on the panel by Holbein, and, in fact, formed no part of his original scheme. This, however, requires further verification and consideration. It is unfortunate that the picture should not have been sent to the Guildhall Gallery, if even only for a brief period, as there would then have been an opportunity for the minute examination of the picture which is almost impossible in the half light of the Hall. So far as I could judge, considerable portions of the work, notably the draperies and many of the hands of the principal kneeling figures on the right, were the portions most advanced by Holbein himself, and these portions appear to me almost free from repainting or other injury by so-called restorers. Of the heads two only remain, I think, much as Holbein left them, somewhat abraded and thinned, but not materially painted over; but these even, though far advanced, do not seem to have been quite completed by Holbein."

This criticism is extremely valuable, and is certainly fairer than the wholesale condemnation passed upon it in Wornum's *Holbein and his Times*, and in Woltman's *Life of Holbein*. It appears that the Barbers' Company, after due consideration, have decided not to send the picture to the Guildhall Gallery. It will therefore remain for the present where it is, and where it has been since it was painted in 1540.

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held in the Council Room of the Association, at No. 429, Strand (corner of Agar Street), London, on Wednesday the 28th day of October next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary*.

September, 1895.

NOTICE OF LAST QUARTERLY MEETING FOR 1895.

ELECTION OF MEMBERS.

A MEETING of the Council will be held on October 23rd, 1895. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before the meeting—namely, October 2nd, 1895.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, *General Secretary*.

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION

MEMBERS are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the

Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 2 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

SHROPSHIRE AND MID-WALES BRANCH.—The annual general meeting will be held at the Salop Infirmary on Tuesday, October 16th, at 3 o'clock. Members who wish to bring forward any business, to read papers, to show cases or specimens, or to propose any new members, are requested to communicate with the (Honorary Secretary not later than Saturday, October 14th.—H. WILLOUGHBY GARDNER, Honorary Secretary, Swan Hill, Shrewsbury.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.—Amended notice of meeting. The next meeting will be held at the Crown Hotel, East Grinstead, at 4.15 P.M., on October 14th, Mr. F. E. Wallis, in the chair. Dinner at 3.15. Charge 3s., exclusive of wine. Notice of communications, etc., should be sent to the District Secretary, J. W. BATTERHAM, M.B., Bank House, Grand Parade, St. Leonards.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.—The next meeting will be held at the White Hart Hotel, Belgate, on Thursday, October 16th, at 4.15 P.M., Mr. F. E. Hollowes, of Redhill, in the chair. Dinner at 6 P.M.; charge, 1s., exclusive of wine. Agenda: Minutes of Croydon meeting. To decide when and where the next meeting shall be held, and to nominate a member of the branch to take the chair thereat. Discussion on *Leishmania*.—Introduced by Dr. Sidney Martin. Speaker: Mr. H. G. Farmer, who will show some cultures and slides. Medical: Dr. Washburn. Speakers: Dr. Holman, Dr. Galton, Dr. Adeney, Dr. J. G. Ogle. Surgical: Mr. C. J. Symonds. Speakers: Dr. Walters, Dr. Hodges, of the South-Eastern Fever Hospital. In its Relation to Public Health: Dr. R. B. R. Sweeting, Local Government Board. Speakers: Dr. Philpot, M.D. H. Croydon, Dr. Jacobs, M.D. H. Belgate. All members of the South-Eastern Branch are entitled to attend and to introduce professional friends.—HENRY J. FRANKLEY, Honorary Secretary, 161, Anerley Road, S.E.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.—The next meeting of this district will take place at St. Bartholomew's Hospital, Rochester, on Friday, October 16th, Mr. J. Holroyde, of Hamond Hill, Chatham, in the chair. Gentlemen desiring to read papers or exhibit specimens are requested to communicate with the Honorary Secretary, E. GROUND, M.B., 1, Ashford Road, Maidstone, as early as possible.

SOUTH-WESTERN BRANCH.—A very kind invitation has been received from the President and members of the Dorset and West Hants Branch to the South-Western Branch to the next meeting, which will be held at Bournemouth, Bournemouth, on Wednesday, October 16th, when Dr. Radcliffe Crocker, Physician to the Skin Department, University College Hospital, will give an address on the Treatment of Inflammations of the Skin. Those members who purpose attending are requested to send their names before October 8th to the Honorary Secretary, W. V. Lush, M.D., 19, Frederick Place, Weymouth, who has kindly promised to forward the agenda and other particulars.—W. GORDON, Honorary Secretary, Barnard Lodge, Exeter.

NORTH OF ENGLAND BRANCH.—The autumnal meeting will be held at the Hydro-Pathic Establishment, Hexham, on Thursday, October 8th, at 4 P.M. The Honorary Secretary will be glad to receive notice of communications. The dinner after the meeting will be at the same place, at 4.45 P.M.; 5s. 6d. each, wine extra.—G. E. WILLIAMSON, F.R.C.S., 8, Eldon Square, Newcastle-on-Tyne, Honorary Secretary.

SOUTH MIDLAND BRANCH.—The autumnal meeting of this Branch will be held at Olney on Thursday, October 8th. The following papers have been promised.—Mr. H. A. Milligan: Two cases of Intestinal Obstruction successfully treated by Abdominal Section. Mr. George H. Percival: Some cases of Ovariotomy. Mr. W. H. Bull will bring forward a proposal: "That a provincial medical association be formed, in conjunction with the South Midland Branch, to combat the growing evil of commercial 'medical aid societies' in the South Midland Counties."—CHARLES JAMES EVANS, Honorary Secretary, Northampton.

WEST SUSSEX BRANCH.—The autumnal meeting of this Branch will be held at the Railway Hotel, Brighton, on Friday, October 25th, at 5 P.M. Dinner at 4.30. The subject as settled by the Council for discussion after dinner will be Club Practice, and the discussion will be opened by Mr. Abbott. Short papers or cases may be taken before dinner, and others afterwards. The Honorary Secretary will be glad to receive notice of any case or paper to be communicated at the meeting in the course of the next three or four weeks.—W. M. KELLY, M.D., Honorary Secretary, Brighton.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT. The 15th meeting of this district was held at the Deaf and Dumb Asylum, Margate, on September 12th, at 3 P.M.; Mr. Bertram Thornton, Medical Officer to the institution and Surgeon to the Sea-bathing Infirmary, in the chair. Twenty members and visitors were present.

Business.—The minutes of the last meeting were read and confirmed.

Election of Chairman for Next Meeting.—It was resolved that Dr. Wilks, of Ashford, should be invited to take the chair at the meeting to be held at Canterbury in November.

The Education of Deaf Mutes.—The CHAIRMAN (Mr. Thornton) introduced this subject by pointing out that about 1 in 2,000 of the population of England were deaf mutes, and he argued that the subject did not receive from medical men the attention it deserved. After describing the two classes of deaf-mutism, brief allusion was made to the etiology and pathology of the condition. The "sign" and the "oral" systems of education were then described at some length, the relative merit of the two methods was discussed, and Mr. Thornton strongly favoured the pure "oral" system as more suitable for the majority of cases. In conclusion, emphasis was laid on the early recognition and active treatment of ear disease in young children in order that, even when the organ has suffered serious lesions, every possible remnant of hearing and speaking power should be preserved. He also pointed out the importance of beginning the training of deaf mutes at an early age and especially insisted on the necessity of systematic examination of all children with regard to their refraction and on the desirability of correcting all errors of vision by means of the ophthalmoscope at as early an age as possible.—Mr. Thornton's paper was discussed by Dr. SHUTTLEWORTH (London) and Dr. ELLIOTT, Superintendent of the Asylum.—Dr. ELLIOTT then gave a most interesting demonstration on some of the children in the institution, taking separate groups, according to the severity of the cases, and showing the wonderful results that had been obtained even under the most unpromising conditions.

Faucial Sequelæ of Scarlet Fever.—Dr. LATTER (Folkestone) read a paper on the Faucial Sequelæ of Scarlet Fever. These were chiefly post-scarlatinal diphtheria, coccid-diphtheria, and ulcerative stomatitis. The connection of these diseases with undue aggregation of convalescents from scarlet fever was illustrated by an account of an epidemic at Gore Farm Convalescent Hospital. A short account was given of pseudo-coccid-diphtheria. The variety met with by Dr. Latter exhibited a thin pellicle on the fauces, soft palate, or uvula, accompanied with great physical prostration, slight elevation of temperature, and, occasionally, rapid wasting. Clinically, it was hard to distinguish from true diphtheria, and differed only in the absence of sequelæ. Bacteriologically, the pellicle showed strepto- and staphylococci, but never the Klebs-Loeffler bacillus. Dr. Latter urged the importance of ample air space for scarlet fever convalescents, and the absolute necessity of bacteriological examination in all cases of doubtful sore throats.

Cock's Operation.—Dr. HALSTED (Ramsgate) read notes on, and showed a case of recovery after Cock's operation done for impassable stricture and extensive extravasation of urine with cystitis. The patient was 76 years of age, and since the operation he micturates through the opening in the perineum every three hours, without any discomfort or soreness, or wetting of the clothes.

Votes of Thanks.—Tea and coffee were served in the asylum at the termination of the meeting; and hearty votes of thanks were given to Dr. Elliott and to the Committee of the Asylum for their kindness and hospitality.

PARIS.

Hysteria in Marshy Districts—Vaccination and the Influence of Weather—Music and Therapeutics—The Detection of Horsesleek in Sauvages—Money and Microbes—Stays and Health—A Patient Sued—General News.

Dr. TARNIER published some time ago in the *Archives de Neurologie* a paper on hysteria in the Vendée which attracted the attention of the medical men of that department. It seems clear that in the marshy part of this province paludism plays a certain part in provoking a series of morbid phenomena impossible to class under any other neurosis. At the present moment events are in process of evolution in the marshy part of La Vendée which indicate the connection of paludism with nervous trouble. A young girl sees in visions the Virgin Mary and people flock to her to be cured. It is stated

that this visionary, who is delicate and ailing in appearance, has entered a hospital to be treated.

Dr. Marty, an army surgeon, states that the time of year has an influence on the success of revaccination. It is generally believed that vaccination direct from the heifer is not influenced by the season, whereas vaccination with vaccine lymph should be practised in cold weather. Dr. Marty has observed that under these circumstances vaccination has a slower evolution. The following table gives the exact results:—

Date.	Cases.	Successes.	Per Cent.
January ..	279	134	44.44
March ..	848	502	59.19
April ..	497	141	30.60
May ..	948	336	35.44
August ..	707	88	12.44
September ..	690	74	9.02
October ..	635	105	21.25
November ..	2,655	1,138	42.48
December ..	1,992	384	51.84

The most favourable months for vaccination are November, December, and March.

Dr. Ferraud in his paper read before the Paris Medical Academy on the physiological influence of music, states that it powerfully modifies the activity of the nervous system, and should be classed in therapeutics among the antispasmodics. Music, according to its character, can act as a simple antispasmodic, as a stimulant to the nervous system, or the reverse. In treatment, the character of the music prescribed must be stated.

M. Nocard, at a meeting of the Conseil d'Hygiène, recommended the following method for detecting the presence of horseflesh in sausages, etc. Boil the substance for half an hour or an hour in four times its weight of water, or steep it in cold water during twenty-four hours and filter. Then add, when the fluid filtered is cold, 5 per cent. of hydrochloric acid; filter again, pour a few cubic centimetres into a tube, then drop on the inside of the tube a few drops of water saturated with iodine. A brown-red-violet ring appears. Instead of a saturated solution of iodine, Gram's liquor can be used, and the coloration is more intense. This coloration appears also when cows' foetus is used in sausages, or of sheep.

M. H. Vincent, in the *Revue Scientifique*, states that certain precautions ought to be observed in handling pieces of money. They teem with microbes, especially those of supuration, the bacillus of tetanus and of tuberculosis. Gold pieces are less infected, probably because their circulation is more limited. Not long ago the dangers of medical fees was pointed out, and it was suggested that medical men should receive their golden fees in hermetically closed boxes, and that they should be subsequently disinfected by the receiver. When in bank notes, these should be handed to them already disinfected in an antiseptic solution. How to disinfect change given by omnibus conductors is a more difficult question.

Madame Gaches Sarraute at a recent meeting of the Medical Sanitary Society, read a paper on the hygienic results of wearing stays. Her conclusions were as follows: If stays are necessary for the comfort of women, they ought to be made on the following principles: They ought not to be high that the stomach cannot expand freely, the upper edge of the stays should be loose and soft, so as not to incommode the ribs. The waist in the stays should be well marked in the back, and in front this should not be so in order that the abdominal viscera should not be incommode. According to Madame Gaches Sarraute, the lower border of stays should reach the pubic bone, and offer the same support as an abdominal belt.

A patient has been sued by a medical man under the following circumstances. From 1883 to 1886 attendance was given for a fee of 4s. 8d. a visit. In 1886 the patient underwent a very serious operation performed by a celebrated surgeon for a fee of £50. After the operation the doctor in general attendance paid 27 visits, and charged 10 francs a visit. The patient refused to pay more than 5 francs. The Court de-

cided that the visits subsequently to the operation involved more care and skill than those previous to it, ordered the payment of the said fees to the plaintiff, with interest and costs.

M. Abbadié and M. Viollet, members of the Institute of France, and M. Isaac, Senator, have in the name of the "Société de Protection des Indigènes" asked the War Minister to extend to the natives of Madagascar the privileges of the Geneva Convention. The War Minister replies that the wounded Malgaches are tended and treated like the French soldiers and allies.

The President of the Republic has visited the hospitals at Havre; at the General Hospital he left a donation of £12, and at the East Hospital £8.

A hair cutter and copper at Paulin, practising as a dentist without any diploma, whilst drawing a tooth sawed away with it a piece of the jaw. He has been fined for practising illegally. He pleaded he learned hair-dressing in Germany, and there all hair-dressers take out teeth. The excuse was rejected by the court, and Dr. Brouardel is commissioned to examine the plaintiff.

MELBOURNE.

The Melbourne Hospital Election.

THE election of surgeons and physicians to the Melbourne Hospital is over, and the result has been declared. There were 31 candidates for 18 places, 8 of these being for the in-patient staff, these being naturally, and perhaps only properly, those most sought after. In this department the old members of the staff have been re-elected, namely, Drs. Williams, 2,674 votes; Springthorpe, 2,481; MacInernay, 2,331; Moloney, 1,962. Surgeons: Messrs. Stirling, 2,632; Fitzgerald, 2,310; Bird, 2,272; Ryan, 2,249. The subscribers also re-elected the whole 10 of the old out-patient staff, namely, Drs. Nihill, Boyd, Daish, Howard, and Lawrence, and on the surgical side Messrs. Noyes, Syme, Rennie, Moore, and Langlands.

In mentioning these names it may be assumed that if the voters had had the choice of the whole profession in this metropolis they could not have made a better selection. But the truth is that many eligible men recoiled from the indignity of having to encounter the degrading work of canvassing and advertising apparently required of those who seek the honour of a connection with this charity. Perhaps, to most of the candidates in this late competition the opportunity afforded of self-adulating advertisement was eagerly seized upon. They had proclaimed themselves for several months before the day of election both by direct announcement and by newspaper paragraphs obtained by various kinds of influence. They had thus, a double chance, they might be elected which was what they hoped for, or if not elected, they were certain to be much talked about. It may be concluded, therefore, that none of the candidates in this scramble have been entirely disappointed.

Everyone has got something of value to him. They are all happy, although in various degrees. They have not all hit the target in the centre, but they have all hit it somewhere. And the public who know nothing of medical ethics, and who, if they did, would not care anything, have had the amusement of witnessing thirty-one members of what is theoretically supposed to be an ennobling profession engaged in a scrimmage which, perhaps, has its aptest parallel in a football match, with this difference, that in the hospital fight it has been every man for himself. But the moral of this contest, so far as the collective medical profession is concerned, is this: that medical ethics represent an exploded sentiment; that to refrain from announcing oneself as a great deal wiser and cleverer and better qualified than one's fellows is a weakness to which only old world delicacy clings, and that *saute qui peut* and "the devil take the hindmost" are the aphorisms worth adopting. Of course the defence offered for this charlatanic quacksalverism is the old one that the mode of electing the Melbourne hospital staff renders such appeals unavoidable. He who blows his trumpet loudest, and beats his big drum most incessantly, is, say they, heard the furthest. These conditions, they insist, are the conditions essential to success, so they are

complied with; and until a different method of election is adopted, it is not likely that there will be any alteration in the methods resorted to by candidates to obtain the support of those to whom they appeal. An incidental and by no means improbable consequence of this disregard of professional amenities is a general extension of the practice of advertising; for the competition among medical men is now so great, owing to the steady increase in their numbers in this colony, that, on the "needs must when the devil drives" principle, we may presently be all placarding the boardings with autobiographical notices of ourselves, accompanied by more or less fearsome portraits, for it is quite certain that this kind of self-laudation pays.

If advertisement and puffing paragraphs may help a man on to the hospital staff, why may they not also fill his consulting room with patients, and so enlarge his bank balance? Out of 5,700 voters on the list about 87 per cent. voted. It is now virtually agreed upon that the present method of election is not only degrading to the profession but demoralising all round. The tenure of office is only four years, and there exists no reason why it should not be longer. The revenue of the hospital is about £21,000, the Government contributing of this £12,000 and £1 subscribers about £3,500. It is these latter, with the life-governors, who decide and control the elections. The Government, strange to say, exercises no voice in the matter. Some little while ago Professor Elkington proposed a scheme of election which at the time found favour with many, which was to the effect that a body consisting of certain members of the medical profession, of the University Senate, and of the committee of the hospital should form an elective committee. The subscriber knew nothing of the merits of the candidate, and was therefore not considered, but although the scheme showed weaknesses it was still preferable to the present mode of election. A very much simpler mode, and which at the present moment seems the most popular, is to allow the members of the present staff to retain office for either a period of fifteen years or until the age of sixty is reached. The vacancies as they occur in the in-patient department to be recruited from the out-patient staff, and vacancies in the out-patient staff to be filled up by an election of the subscribers. This is the scheme which the staff will shortly endeavour to induce the committee to adopt. It is sincerely hoped that this election is the last of its kind, and that the whole profession will resent any further attempt to render it ridiculous, to lower its prestige and destroy its ideals by dragging its traditions through the mire.

CORRESPONDENCE.

SANITARY PROGRESS IN INDIA.

SIR,—Mr. Ernest Hart is making a great effort on behalf of Indian sanitation. He is heavily handicapped, because in the entrance examination for the Indian Medical Service in London no marks whatever are given for sanitary knowledge. A man might be a D.P.H., and yet not gain any advantage from having it.

Surely this is wrong, and in a medical preventive service sanitary science should count for much. If Mr. Ernest Hart will get the India Office authorities to offer 1,000 marks for sanitary science, as they now do for anatomy, he will soon see good results. Anatomy may be overmarked in such examinations. —I am, etc.,

Sept 17th.

TWENTY YEARS IN INDIA.

MEDICAL MISSIONARIES AND PRIVATE PRACTICE.

SIR.—If the "protest" published under the above heading in the BRITISH MEDICAL JOURNAL for August 17th is to lead to any useful discussion, "Vindex" ought first to furnish us with precise data. Rajputana is a very wide word, will he favour us with the exact whereabouts of himself and the peasant medical missionaries?

Then, again, there is no "Colonial Missionary Society" at work in India.

Several missionary societies, and a number of medical missionaries are at work in Rajputana; but it is not possible

to discuss the protest of "Vindex" until we find the range of his guns.—I am, etc.,

H. MARTYN CLARK, M.D., C.M. Edin.,
Medical Missionary, Church Missionary Society,
Unrishtur, Punjab.

Sept. 2nd.

THE THROAT HOSPITAL, GOLDEN SQUARE.

SIR,—While we thought it expedient to announce publicly the severance of our connection with the Throat Hospital, we did not think it necessary in the interests of the institution to state at the time our reasons for so doing. As, however, others think differently, we now ask you to publish the following statement.—We are, etc.,

SUTHERLAND.

R. COURTENAY WELCH.
GREVILLE MACDONALD.

STATEMENT.

At the annual general meeting of the governors and subscribers of the Throat Hospital, held on April 10th last, after Mr. Courtenay Welch and two others of the retiring members had been unanimously re-elected, four other gentlemen (Dr. Norris Wolfenden, a former member of the honorary medical staff of the hospital, Major Probyn, Mr. Allom, and Mr. Osborne) were, after opposition, elected to serve on the Committee of Management. A few days later it was discovered that among those who had voted in support of these gentlemen were several persons who, in order to obtain a colourable qualification to vote under By-law 16 ("No annual subscriber shall be entitled to vote until after the payment of his subscription for the second year"), had, a few days before the meeting, paid to the secretary a subscription, with the request that one moiety should be entered as a subscription for 1894 and the remainder as for 1895; one of the four gentlemen thus elected having himself in this manner obtained his qualification to vote. Although some of these payments were made just before the monthly Committee meeting of April 2nd, the Secretary made no mention to the Committee of this unusual procedure; nor did he at the annual general meeting, when the qualification of one voter was challenged, give any hint that anything irregular had taken place.

At the next Committee meeting, held on May 7th, Dr. MacDonald proposed, and Mr. Welch seconded, a resolution to the effect that a special general meeting of the governors and subscribers should be called to reconsider the opposed resolutions passed at the annual meeting. When this proposal was rejected, and the Committee thus refused to allow the question to be reopened and the facts laid before the subscribers, Dr. MacDonald and Mr. Welch at once resigned.

The Duke of Sutherland, at the earnest request of Mr. G. H. Pember, the new chairman, and of Dr. MacDonald, who, acting independently of each other, pointed out the irreparable injury which his Grace's resignation would inflict upon the hospital, consented to defer any definite step until it could be ascertained whether the four gentlemen, the validity of whose election had been called in question, would voluntarily retire. A deputation from the Committee subsequently waited upon the President; but as the arrangement he had suggested was not carried out, he had no alternative but to resign.

"A QUESTION OF CONSCIENCE."

SIR.—In the BRITISH MEDICAL JOURNAL of September 14th Dr. Arabella Kenely asks for help in deciding how to act in a "question of conscience" under circumstances very interestingly and graphically narrated, which may be thus abbreviated. Dr. A. Kenely was called to the wreck of a young woman early married. She had had three abortions, then one living child, two other abortions follow, and the third is threatening to occur. Whilst considering the case downstairs she sees the only outcome of this marriage—a miserable fragment of humanity—and she asks herself, though not in these words, if the fetus now threatened to be expelled is to be a repetition of the one then before her, would it be wise to save it? In addition she asks, if we can save it from expulsion, can we cure it? and further discusses the power of mercury over syphilis, and also of other remedies, and the nature of cures.

"Thus there are many separate points raised which it would be impossible to go into in a single letter; but the essence of the "question of conscience" has doubtless occurred to most thoughtful minds both within and without the medical profession. It is this—supposing we have the power of checking abortions, so endeavouring to bring the foetus to maturity, are we wise and therefore right in exercising it? Of course we have now only regard to the foetus: the fact that we know the one or both parents are syphilitised does not affect the question, and before we can answer it we ask other questions. Do we know the actual condition of the ovum and, particularly, of the foetus, how far it is damaged? Is the uterus rebelling against an unwholesome thing or influenced by reflex agencies only from mind or body? Is every fruit of a syphilitic parentage so far affected as to render it useless to others and a misery to itself? How far does our most penetrating glance, our keenest vision, enable us to determine the actual use or value of any human being?

When called to cases of this kind these questions naturally crowd themselves on my mind, and recognizing the impossibility of answering them satisfactorily, with the occasional exception of uterine action caused by mental or bodily reflexes and cases where the signs of the death of the ovum are manifest I have had to draw rules for guidance from my previous experience, and it may be thus briefly stated—that in those cases of threatened abortion the symptoms subsided and pregnancy continued, that the children in a considerable proportion turned out satisfactorily. Of course some were weakly. Though in my early life I felt that theoretically the expulsion of the ovum was not to be regretted, yet afterwards I learnt that those that arrived at maturity were worth preserving.

It must not be concluded that every child of syphilitised parents will turn out a blighted life, far from it, a large number make excellent and valuable citizens.

In view, therefore, of our uncertainties and of our defective insight as to the present and of our absolute blindness as to the future I would say, that if we have the power of checking these abortions, it will be wise, and therefore right to exercise that power. And that we do possess by various means such a power, I have no doubt in a considerable number of cases.

But the principle underlying our rule of action here discussed is of far wider application than to the case of abortions, for, if it be right to suspend treatment in what we guess to be Nature's wisdom, so we should, in the event of Nature's apparent failure, be wise in interfering in the opposite direction, and to this end adopt measures to cause and assist Nature to expel its contents, which we guess to be in a damaged condition; but this, my experience has shown, would in the long run be destructive of a considerable number of foetuses that might, for ought we know, have become ornaments and useful members of society.

And so, how can we logically limit this principle to the treatment of abortions alone? Why not apply it to the newborn infant which to us seems to be ineligible to live, and in the poor morsel of being, described only too truly, why not refuse it succour; and why not assist it out of its troubles in a dream of euthanasia? and the limit cannot rest here; we must apply the principle through all medicine and surgery; and not least in mental diseases. Where can we stop? And all this on the assumption that we have a perfect or sufficient knowledge of the future to guide us to such momentous issues. The principle goes yet further before we can arrest our trembling steps. Shall we save a life in danger, which life we know to be base, villainous, dangerous? Shall we let such a one drown whilst we stand by with folded arms though with power to save?

When I first began my professional life the goal placed before us was this: To relieve suffering humanity and to prolong life by every means possible, though but for a minute, even at the risk of our own, leaving the event to Providence. Is this rule dead? If not, then it is clear that even with the fears before us it would be not possibly unwise and therefore not wrong in doing what we can to enable the uterus to tolerate the presence of its contents till we have proof of their death or the jeopardy of the life of the mother.

There is not space to discuss now what "cures" we can

effect on the syphilitised foetus, or whether the poison affects the foetus so much as the apoplexies which it causes cuts off its nutriment; nor the other points raised; yet the "conscience questioner" may somewhat console herself when she thinks of the ever-widening stream of taint that as it widens it becomes shatower, and that this stream has "Nature's vast reparative power" as its sandbanks.—I am, etc.,

George Street, W., Sept. 18th.

J. BRAXTON HICKS.

SIR,—I have just read Miss Arabella Kenealy's letter and would like to tell her a story; albeit not in her poetic style, which may be of use to her. In 1870 I entered into partnership with an old practitioner in a town in Worcestershire, and one of my first patients was a handsome young woman, the wife of a tradesman, whom I was called on to attend in labour.

She gave birth to a dead syphilitic macerated foetus, at about eight months. I was informed that the same thing had happened twice before. I could not venture to speak. I consulted my partner, and he informed me that he had treated this woman for syphilis some years previously before she married, but she was only under treatment a few weeks. I had just read Diday's book.

In the following year she came to me saying she was pregnant four months, and asking me the cause of her sorrow, inquired could nothing be done that she might have a living child. I explained to her the cause and said "You will have another dead child, then I shall treat you and you shall have a living one."

Now comes the question of conscience. "Why not now?" she asked. "Because it is not expedient that the child at present in your womb should live." I considered that no treatment could make such a change in it as to make life anything but a curse.

Between seven and eight months she was again delivered of a dead child. I then put her under mercurial treatment. In twelve months she had a perfectly healthy son. I put this son under mercury for twelve months, keeping up the mother's treatment uninterruptedly for three years. She had three more perfectly healthy children in rapid succession, which were not treated separately.

Two years ago I visited the town and found them out and four better grown, better looking (they had all their mother's beauty) or more intelligent young men and women you could not find in their station in life, two were married and had healthy children. The husband does not know till this day.

Some lessons are to be learned from this case:

1. Women are not the only ones who are wronged and deceived.

2. Miss Arabella Kenealy will have to modify her views as to the mercurial cure, and (in parenthesis) she will also modify her others with experience.

3. What effect the same treatment would have had upon the four months foetus and its future fate I cannot tell, but I dared not try, and Miss Kenealy's conscience and mine, I think, are at one on the question.—I am, etc.,

Dover, Sept. 21st.

JOHN ORMSBY, M.D.

SIR,—Dr. Kenealy raises certain questions which must interest us all, and as she asks for criticism I trust she will accept my remarks in the spirit of one who is merely anxious that the well-understood principles of our action as medical men should not be eclipsed by vague generalisations, for ours is a severely practical profession.

It seems to me that the first mistake is in mixing up abstract speculation with what should be the practical considerations of a healer of the sick. When one takes up the latter rôle surely the one duty and responsibility is to do the very best for our patients, even although, as everyone must admit, we have very often but a farthing rushlight wherewith to work instead of the clear light of noonday, still the moral burden is on us to do all we can under the special circumstances, however little it may be, and it will be a bad day for our profession if ever we depart from this.

Taking the concrete cases on which Dr. Kenealy bases her remarks, it seems, if I understand her aright, that because she cannot do everything therefore she will do nothing, and in so doing she departs from first principles which should have guided her. The case is quite a clear one of threatened

abortion due to syphilis, and her conduct of the case up to the library scene is what all of us would have done.

The sight of such an unfortunate child could not fail to produce the deepest compassion, and even indignation, when one records the fact that syphilis is a preventable disease, but when this induces Dr. Kenealy to tear up her prescription surely it is mere sentimentalism, and also a running away from the bounden duty of relieving the unhappy mother and yet unborn child, to save whom she was called in.

Dr. Kenealy goes on to excuse herself on the ground that to interfere with the natural course of the case is to violate a "physical conscience." Now, what are the facts embraced in this term? Merely, that when a woman is suffering from syphilis she is very liable to abort. We know as a matter of practical experience that mercury carefully administered, or in some cases iodide of potassium, will not only prevent this, but will have a most beneficial influence on the mother, restoring her health, and preventing future abortions, enabling her to bear fairly healthy children, and also that the unborn babe will be equally benefited. There can be no question, I imagine, that it is our bounden duty to, at least, aim at this end.

Dr. Kenealy allows the argument from analogy—a most fruitful source of error—to cloud her mind, and blind her to the practical side of the question, acting as an abstract moralist, a part she was certainly not called in to play. As to the ill effects of mercury, may I, in all humility, not say that these are due to want of care and inattention to the general health.

I feel sure Dr. Kenealy's action will be condemned by the general sense of the profession. Arguing as Dr. Kenealy does, I think she was bound from a logical point of view to procure abortion, in order that the "physical conscience" might not be violated.

The general statements which occupy the latter part of the letter would, in my opinion, not stand the test of destructive criticism. I should be very sorry if anything in this letter led anyone to suppose that any medical man can see such cases without deeply sympathising with the unfortunate sufferers, but the remedy is social, and lies outside our profession; nevertheless, it is our duty to do all we can, both morally and physically, to render syphilis an unknown disease, and so confer on our race an incalculable benefit.—I am, etc.,

London, E.W., Sept. 14th.

M. G. BIGGS.

SIR,—Miss Kenealy is a lady who possesses the courage of her convictions, for few of her brother practitioners will regard her action as anything but morally indefensible. To purposely refrain from interfering to prevent abortion does not differ in principle from actively bringing it about, and the question she has raised resolves itself into whether it is justifiable in the interest of the child to procure abortion when the parents are syphilitic. If we admit the justifiability of abortion in these cases, we must also admit that it is justifiable when the parents are phthisical, for phthisis is far more loathsome and more painful than syphilis; and if justifiable in these cases, it is also justifiable in other diseases which may entail future suffering on the offspring. The logical conclusion is that preventive treatment must consist in procuring abortion whenever there is a chance that the child will inherit any tendency to disease—a radical method of eliminating unhealthy strains in the race. As doctors we must regard life as sacred, and it is our plain duty to strive to save or prolong life as long as we can, when we have to treat our patients, and only when another life is threatened are we justified in contemplating any measure which will destroy life. Whether the life we are striving to save is or is not of value has nothing to do with us.

If we allow exceptions to this golden rule the thin edge of the wedge is inserted. Allow a doctor the right of deciding whether he shall kill or cure, according as he deems the particular life to be of value or not, and the most terrible abuses will most certainly follow.

In a world in which pain and suffering are the only realities, if anything indeed is real, it is not for us to decide the question of existence. However much Miss Kenealy's emotions may have been affected by the sight of the syphilitic child previously born of the same parents, she took upon

herself a grave responsibility when she indirectly helped to bring about abortion by refraining to give the proper remedies. Her duty obviously was to have done her best to enable the birth to have taken place at the proper time, and by judicious treatment to have mitigated the ill to which the child was heir, seeing that she was called in and paid by the parents for this purpose.

Lately much hysterical rubbish has been issued to the world in the pages of semi-erotic novels on this subject of syphilis; and although works such as *The Heavenly Twins* are calculated to disturb the equilibrium of their lay readers, members of our profession should at least be above that weakness. Even if the evils of syphilis were as great as they are represented to be in these pernicious books, nothing can justify a doctor in breaking the golden rule of his profession, and in destroying life because his emotional facilities have been strongly affected.—I am, etc.,

Dover, Sept. 15th.

A. G. WELSFORD.

SIR,—The writer of the letter headed "A Question of Conscience" has not, I take it, caught her foot in a rut of conventional professional procedure, but has rather, with eyes wide open, though blinded by auto-suggestion, walked along the dirty gutters of morbid sentimentality and more than doubtful morality, and now calls out for us to admire her mudstained boots.

The doctrine that we may determine who are fit to live and who are not—for this is what her practice really comes to—has for some time past been abandoned by civilised nations, and although the race would doubtless be improved if the doctrine could be successfully applied, it is, apart from other considerations, too dangerous a one, for man and woman too is prone to err.

Why if one child has been stamped with congenital syphilis, possibly without any attempt to prevent it, should we withhold such relief as we possess, even if, "in some way not understood, it only so modify the evil that it should not show eruption on the outside"? We are told because there is no such thing as "cure" in medicine, and therefore forsooth we are to withhold the admitted chance of preventing the outward sign of disease; in other words, because we cannot do everything we may not do anything.

Surely our civilisation is a failure, and the Caucasian is played out when we descend to cutting off other people's noses to spite our own feebleness; and the Caucasian had better give place to the Mongolian if we must hesitate to relieve pain by opium because it dulls the senses to the fact of injury, which is often the very thing we ought to do—for example, in severe burns.

The Caucasian is learning now, and the Mongolian in Japan is helping him, that disease, when prevention has failed, is to be attacked not directly, but indirectly; and that, as is shown by the ideas of antitoxin and defensive proteid treatments, our remedies do good only in so far as they enable the tissues to resist morbid processes. Still, if on this account there are, strictly speaking, no such things as specifics, we should not refuse to administer remedies which are of some service. To quarrel with mercury because its administration is not always followed by the desired success, or, what is more likely, because, although it is a constant, the individual to whom it is given is a variable, quantity, savours not of wisdom, but of "visions about."—I am, etc.,

September 15th.

J. N. C.

SIR,—The writer of the letter in the *BRITISH MEDICAL JOURNAL* for September 14th, entitled "A Question of Conscience" opens up the very important question as to how far any individual has the right to make himself the judge of whether or not another human being is fit to live, and to withhold from him his chance of living. To do so is to accept a responsibility which to my mind is far beyond that which any man or woman individually should assume.

The mother of the foetus in question trusts to the honour of her medical attendant to give both her and her child the best chances of life and health available; and whatever may be the opinion of Miss Kenealy of the exact degree of value of mercury as a "cure" for the disease, being convinced, as she seems to be, that it is the one drug offering any chance

of improvement, however little, she will in my opinion be neglecting an obvious duty both to her patient and to society if she fails to make use of it.

General experience shows that a syphilitic mother often gives birth to a child who afterwards becomes a useful member of society; that the syphilitic virus becomes attenuated so that the children of successive pregnancies are less and less affected, and that a practically healthy child may be born where mercury has been given during pregnancy, while in the next pregnancy abortion may occur, or a child with marked syphilitic lesions be born, if no treatment is adopted.

Miss Kenealy says that no such phenomenon as a cure is known in the whole range of medicine. But if the above be true—and I think it represents the experience of most—we may not say that, for practical purposes, a cure has been worked, and that the growing tissues have been so influenced as to lead to the production of an organism too good to be thrown away? At all events, no person to whose honour a patient entrusts her life and that of her child ought to answer that question in the negative.

The writer, in a pessimistic mood, calls in other drugs as parallel instances to support her views. I venture to think, however, that, if space permitted, arguments might be adduced to prove that, at all events in the cases of salicylic acid and quinine these statements are incorrect.

In conclusion, I ask her to again reconsider the question before taking a course of which the general body of practitioners cannot but disapprove, and which, if generally adopted, would justly shatter the confidence of society in our profession.—I am, etc.,

September 17th.

R. E.

THE EDUCATION OF THE STUDENT IN PRACTICAL MIDWIFERY.

SIR.—In the *BRITISH MEDICAL JOURNAL* of August 17th and 24th Drs. Divine and Don object to my remarks and to those of Mr. Wheelhouse relating to the dangerously inefficient training of students in the above subject. The present requirements are disgraceful and disease producing.

The present Recommendation of the General Medical Council is: "No. 18. Every student should be required to attend for three months the indoor practice of a lying-in hospital, or to have been present at not less than twelve labours, at least three of which he should have conducted personally under the direct supervision of a registered practitioner." This infamous recommendation means that a student, before coming up for his final examination, has to show he has "personally conducted" only three labours. This death-dealing recommendation of the thirty practitioners who form the General Medical Council has been sent to many members of the Commons by those in favour of the so-called registration of midwives, and has reflected grave discredit upon us.

In November, 1890, at the session of the General Medical Council it was moved:

That it is urgently necessary for the examining bodies to require of candidates for their diploma additional guarantees of practical education in obstetrics, and that candidates at the Final Examination be required to produce proof that they have personally attended at least thirty cases of midwifery and been attached as pupils for three months to a lying-in hospital, or attendance on the lying-in department of a general hospital or a maternity institution with arrangements for clinical teaching approved by the examining body granting the diploma.

This motion was defeated by 12 to 10 votes. It is disgraceful further to note that it was defeated by the Scottish vote, as Dr. Struthers (Aberdeen University), Sir W. Turner (Edinburgh University), Dr. Leishman (Glasgow University), Dr. H. Watson (Royal College of Surgeons, Edinburgh), Dr. Tuke (Royal College of Physicians, Edinburgh), Dr. Pettigrew (St. Andrews University), Dr. Cameron (Faculty of Physicians and Surgeons, Glasgow), Sir G. H. B. Macleod (Crown nominee for Scotland) voted dead against it. Even Dr. Bruce, the Scottish direct representative, refused to vote, although present.¹

Perhaps Drs. Divine and Don will explain this solid Scottish vote. My advice would be, not to excuse their Scottish representatives, but to urge them to vote differently. They take objection to our criticism of the obstructive tactics

of the late Dr. Leishman. When we consider Dr. Leishman's then position, and the advice he gave the members of the General Medical Council, we can readily see why Mr. Wheelhouse considers it so absolutely misleading. Dr. Leishman's words were: "I could communicate more sound instruction in practical details at the bedside in one case of labour than the student would pick up haphazard in the course of a casual attendance on twenty."² If his statement was not directly antagonistic to the proposed improvement, then I do not know what words mean.

Let us hope the General Medical Council at its next session will take the subject up in a statesmanlike, and not in a pettifogging, narrow, medical school manner. If there be not a sufficient number of lying-in cases in Scotland for students, then let the hospital staffs cease training pupil midwives. Or does it pay better to train pupil midwives? Also, their Poor Law infirmaries should be utilised, while practitioners should take senior students as pupils. Or do the staffs of hospitals fear that the fees of students may pass to other practitioners?

I have looked carefully into this question before I petitioned the General Medical Council to recognise that it has a national duty to perform, besides seeing that the fees of students should not be deflected to other sources. I found that the following table showed the actual requirements of the various (and too numerous) medical examining bodies:

Examining Body.	Lectures in Midwifery.	Clinical Instruction.	Number of Labours to be Attended.
R.C.P. and R.C.S. Eng.	3 months	and 3 months	and 20
Soc. of Apoths., Lon.	3 ..	" 3 ..	" 20
Univ. of London	1 course	" 0 ..	" 20
" Oxford	0 ..	" 0 ..	" 0
" Cambridge	1 ..	" 0 ..	" 20
" Durham	6 months	" 3 ..	" 20
" Victoria	6 ..	" 3 ..	" 20
R.C.P.E., R.C.S.E., and F.P. and S.G.	3 ..	and 3 months with 6 labours	or 12
Univ. of Edinburgh	6 ..	" ..	" 12
" Glasgow	6 ..	" ..	" 12
" Aberdeen	6 ..	and 3 months	" 6
" St. Andrews	6 ..	" 3 ..	" 6
R.C.P.I. and R.C.S.I.	6 ..	" 6 ..	" 30
R.C.S.I. and Apoth. H.	6 ..	" 6 ..	" 30
Univ. of Dublin	6 ..	" 0 ..	" 0
Royal Univ.	6 ..	" 6 ..	and 20

The course of lectures for the London University is optional; while the University of Oxford, since June, 1895, requires attendance upon 20 labours.

At the last annual meeting of our Association, a resolution was unanimously adopted calling upon the Council of our Association to (a) petition the General Medical Council to increase the number of lying-in cases required from 3 to 30; (b) to take steps to having the law altered so that the Poor-law infirmaries may be opened for the clinical instruction of medical students in practical midwifery; and (c) to petition the committees of the three lying-in hospitals in London to cease excluding male medical students from clinical instruction in midwifery.

If the General Medical Council and the Council of our Association do their duty, then this present disgrace will soon be wiped out.

Liverpool, Sept. 18th.

ROBERT R. RENTOUL.

THE UNIVERSITY GRIEVANCE IN LONDON.

SIR,—I am an unfortunate London diplomate with six years' experience in public health work, but my application for the post of medical officer of health to the West Kent Combined District is declined by return of post. The advertisement states that a preference will be given to graduates of London, Oxford, Cambridge, Edinburgh, and Dublin, and this apparently means that all candidates not possessing a degree from one of these Universities are struck out at the first selection.

¹ See Minutes, General Medical Council, November, 1890, p. 26.

² *BRITISH MEDICAL JOURNAL*, December 4th, 1890, p. 1306.

That an English authority in the neighbourhood of London should prefer a Scotch or Irish graduate to a London diplomate is only another sign of the usual lay ignorance on medical matters, but why graduates of other English Universities should be ruled out I do not know.

May I venture to suggest that every London diplomate having qualified as M.R.C.S., L.R.C.P., L.S.A., and D.P.H. should be allowed to apply for the Lambeth degree of M.D.? This degree would not interfere with the vested interests of any university. The fees would be very acceptable to the Church, and the degree would give London men that title of doctor, the want of which tells against them so strongly in their struggle against the, to say the least of it, no better informed graduates of all the other universities, that of London excepted.—I am, etc.,

Sept. 17th.

MEDICAL OFFICER OF HEALTH.

THE QUALIFICATION OF FEMALE PRACTITIONERS.

SIR.—I read with great interest the admirable article in your Educational Number, by Dr. Elizabeth Garrett Anderson, on the Qualification of Female Practitioners. It is full of valuable information to girls who contemplate entering on a medical career, and points out the various schools of medicine where they may attend the necessary classes in England, Scotland, and Ireland. But she unfortunately omits any mention of the Faculty of Medicine organised in connection with University College, Cardiff. The Cardiff Medical School has only existed for two winter sessions, and at present only provides for the first three of the five years of the medical course, that is, until the student has passed his Intermediate M.B. Examination of the London University, or its equivalent in the other British universities, or the Second Examination of the Conjoint Board. But up to this point all the arrangements are excellent, and the staff of professors leaves nothing to be desired. I believe no student who wishes to be prepared for the Preliminary Scientific Examination of the University of London could choose a better school than one of the three Welsh Colleges. Each has a very highly qualified staff of professors, whose main business is to prepare students for this examination, and admirable laboratories fitted up with all necessary appliances. Youths of 17 or 18 are far more likely to get a good start in their student career by being sent to such places as Aberystwyth, Bangor, or even Cardiff, than by being sent into the huge metropolis, with its manifold snares and distractions. But Cardiff carries its students on to the stage of passing the intermediate M.B.Lond. Lectures are given in anatomy by Professor Alfred Hughes, F.R.C.S.Eng.; and in Physiology by Professor Hayercraft, M.D., D.Sc.; and in materia medica by Dr. Paterson; whilst in the dissecting rooms and laboratories, fitted with all the most recent appliances, every opportunity and encouragement are given the student to help him in his studies. I have recently returned from an inspection of the medical school, and have been delighted with the completeness of the arrangements, and the facilities offered the students. Clinical experience, clerkships and dresserships, etc., can be obtained at the Cardiff Infirmary. There are about thirty students at present in the medical faculty, and the fees are very moderate, whilst lodging and living are much cheaper than in London. And the success of the students of these Welsh colleges at the London University is very marked. At the last Intermediate Arts Examination Aberystwyth passed 27, and Cardiff was fourth in the list, passing 6; whilst Bedford College passed 5, and University College, London, 4. In the Preliminary Science list of thirty-three hospitals and colleges Cardiff has the eighth place; whilst three of its students passed also the Intermediate Science Examination, which includes all the Preliminary Science subjects *plus* mathematics.

And one special feature of the Welsh Colleges has been the mingling of the sexes in education. In the University of Wales every post is expressly open to women—even to that of the Chancellor. Sex is no bar to any professorship, or examinership, or office of any kind. And the Cardiff Medical School throws open all its classes, and offers all its advantages, to men and women on equal terms. Both Professor Hughes and Dr. Hayercraft will heartily welcome women medicals, and having determined to send my own daughter to

be under their able teaching. I thought other fathers might like to know that such a medical school exists for their girls, and so make further and fuller inquiries for themselves.—I am, etc.,

September 17th.

T. J.

HOSPITAL ISOLATION AND THE DISINFECTION OF PATIENTS.

SIR.—In Dr. Boobbyer's address at the last meeting of the British Medical Association Public Health Section he says "The same sort of thing is now occurring in another suburb of Nottingham. The presence of an epidemic of scarlet fever is practically ignored by the sanitary authority having supervision of the district, and we on our side are left the unprofitable task of baling a sieve. There are more than sixty cases of scarlet fever in one short street of this suburb, which closely approaches our boundary."

Now, from correspondence which has subsequently taken place between the Town Clerk of Nottingham and the Carlton District Council, I have no doubt that Dr. Boobbyer referred to this district for which I am medical officer of health. In the first place, my means of information enable me to assert that, scattered over the whole district with a population of about 7,000, there were not more than sixty cases of scarlet fever, with no especial concentration in any one street—his statement that there were sixty cases in one street having been absurdly inaccurate. Secondly, directions for isolation at home and disinfection were given in all known cases, and the houses were fumigated after recovery, either privately or gratis by an experienced servant of the Council. The schools were also closed for about six weeks, and the epidemic rapidly abated.

But I quite agree with Dr. Boobbyer that adequate means have not been taken for most effectually coping with infectious outbreaks, inasmuch as there is no infectious hospital and no compulsory notification in force. In my humble opinion, a good central permanent infectious hospital for two or more districts would be more satisfactory than a small one for each district, and that the County Council might undertake the task and, if necessary, call upon each district to contribute proportionately towards its maintenance; or a town like Nottingham might do something in the same direction as a protection against the dangerous epidemics of its suburbs.

I should not have troubled you, Sir, respecting this matter but that Dr. Boobbyer appears to have ignored the Carlton District Council and its officers in procuring information respecting the outbreak previous to giving his address. Whether he thought that information procurable from this source would be biased and less reliable than that which he gleaned elsewhere I cannot say, but I do think such an omission in the first instance in case of an outbreak in a suburb contiguous to his district is not most conducive to effectually battling with it, as any communication or advice from so excellent a source would always, I am sure, be appreciated and respected by those with whom I work and by myself.—I am, etc.,

Nottingham, Sept. 9th.

J. T. KNIGHT,
Medical Officer of Health, Carlton.

PLAGUE HONOURS.

SIR.—I observe in the BRITISH MEDICAL JOURNAL of July 20th, 1895, that reference is made to the two men who stand out pre-eminently before the community of Hong Kong as having devoted themselves to battling with the epidemic of plague in 1894. One, the chairman of the permanent committee, Mr. Francis, Q.C., directed the whole of the work and was elected to the post as the foremost citizen, and the most capable man we had for the work in hand. Yet Mr. Francis is asked to be satisfied with a school-boy reward of "a handsome inkstand." The residents in Hong Kong felt the insult keenly and hope that the Government will yet redeem their position and in justice and common fairness request a more fitting reward.

The other worker who has been neglected in the list of awards has been Dr. J. A. Lawson. Dr. Lawson was in medical charge of the hospital during the entire period of the epidemic. He was indefatigable in his work, and for three long months was on duty night and day.

In the BRITISH MEDICAL JOURNAL of Sept. 8th, 1894, your correspondent wrote: "Dr. J. A. Lawson has earned a lasting name for his fearless devotion and untiring exertions during the whole period of the epidemic. Upon him fell the work of organising and maintaining the sanitation of the hospitals, and very earnest and well were his duties performed." Then follows a request that the work of Surgeon Penny, R.N., and Surgeon-Major James, M.S., be recognised. "The latter officer, Surgeon-Major James, has performed most laborious sanitary duties. He was elected a member of the sanitary board, a member of the permanent committee, and inspecting medical officer for the board during the long trying period whilst the epidemic held the city in its clutches. A colony of limited means with its exchequer bled to the last dollar to cope with the enormous losses incurred by the plague epidemic cannot award nor even pay their officers anything extra for their unsavoury work. It is hard to stand by and see unrequited labour of the high character these medical men have performed without being able to move a finger whereby to obtain some recognition of their services. Surely some channel will be opened whereby true merit and devotion to work in this most trying time may be acknowledged and stamped with a people's approval." I would repeat these statements, and again repeat, can we not get some recognition? The medical men of the Colony, naval, military, and civil, subscribed their names to a petition that the Albert Medal should be bestowed on these three men, but it fell into the wrong channel. May I ask the editor of the BRITISH MEDICAL JOURNAL to take this matter in hand and endeavour to obtain the Albert Medal for our medical fellows?—I am, etc.,

Hong Kong, Aug. 28th.

JAMES CANTLIE.

CLUBS, CHEAP PRACTICE, AND UNDERSELLING.

SIR.—There has been a good deal written in the BRITISH MEDICAL JOURNAL lately on the subject of medical clubs, aid societies, etc. The question opens up a very wide field for reform, and not before it is sadly needed; but as long as the medical profession is so disunited and ready to "cut each other's throats," so long shall we have to work at the present low rate of remuneration. The remedy is in our own hands.

I do not know what the experience of other members may be, but mine is such as to cause me each day to feel more and more disgusted with a body of men who, though belonging to a noble profession, are by their conduct fast making it most ignoble.

Some little time ago a graduate of a northern university purchased a practice in a neighbouring village. He called on me, and afterwards dined at my house. Over our post-prandial pipe I innocently told him the fees I was in the habit of charging. The next thing I heard of this member of our honourable profession was that he had been going round to my clubs offering to take them for fourpence a head less. He is also in the habit of going—accidentally of course—into my patients' cottages and telling them that if he were treating the case he could bring about a speedy cure.

Is there nothing that can be done to check this sort of thing? Cannot our great Association bring forward some scheme to stop it, and thus make themselves of some real service to the general practitioner? Other professions have their remedy for such base conduct, and why cannot we? The regular quack will do us but little harm—it is within our own ranks that the purging is required, and then when we are clean the rest will easily follow. I am, etc.,

Wylie, Bath, Sept. 15th.

C. PENRUDDOCKE, M.R.C.S.

"THEY KNOW NOT THE MANNER OF THE GOD OF THE LAND."

SIR.—In recent issues of the BRITISH MEDICAL JOURNAL, August 31st, page 502, and August 31st, page 520, two letters have appeared under the above heading, to which I trust you will permit me to reply.

In the first letter Staff-Surgeon Kirker attributes the prevalence of enteric fever among British soldiers and sailors abroad to their want of knowledge of the manner of living as compared with that of the natives. I think that anyone who knows the manner of living of native will agree that their mode of life, from a sanitary point of view, is in no way

superior to the Englishman's, except as regards dietetics, and those are, first alcoholic drinks, and, secondly, a larger meat diet.

With regard to the first, it is notorious that total abstainers suffer at least equally with non-abstainers, and with regard to the second it cannot be contended that the Englishman of the present day abroad is a larger meat eater than he of two or three decades ago, yet at that time enteric fever was practically unknown.

In the second letter Surgeon-Colonel Davy apparently attributes this disease to "defective personal hygiene," that is, to want of personal cleanliness. I think all will agree that there is no more cleanly person in existence than the British officer, yet he suffers from enteric fever equally with his comrades in the lower ranks, and I presume no one would advance the idea that the soldier of to-day is less cleanly than he of thirty years ago.

The cause, I consider, must obviously be sought elsewhere, and the factors something that was non-existent twenty or thirty years ago.—I am, etc.,

W. L. CHESTER M.B.

Surgeon-Lieutenant-Colonel, A.M.S.

Cairo, Sept. 14th.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL STAFF EXCHANGE.

The charge for inserting notices respecting Exchanges in the Army Medical Department is 3s. 6d., which should be forwarded in stamps or post office order with the notice. The last post on Wednesday is the latest by which these announcements can be received.

A MEDICAL OFFICER of field rank, who expects to go to India this trooping season, desires an exchange with an officer under orders for a colony. Apply, A. Phagre, General Post Office, Dublin.

A SURGEON-MAJOR serving in Bengal wishes for an exchange which would give him about three years at home. Address, stating terms, to S. L. H., care of Messrs. Holt and Co., 17, Whitehall Place, London, S.W.

THE NAVY.

SURGEON MICHAEL O'BRIEN, M.D., has been placed on the retired list of his rank, with a gratuity, September 17th. His commission was dated August 17th, 1887.

The following appointments have been made in the Admiralty: EDWARD CONCORAN, to the Comus, October 1st; MILARY C. ARATHOON, Surgeon, to the Royal Arthur, September 24th; GERALD T. S. SIBBEL, Surgeon, to the Research, September 24th.

THE ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT-COLONEL JAMES McHARRN retires on retired pay, September 25th. He was appointed Surgeon, September 20th, 1877; Surgeon-Major, September 20th, 1880; and Surgeon-Lieutenant-Colonel, September 20th, 1894. He was in the Boer war of 1881, and was present in the engagements at Lang's Nek and the Ingogo River, for both of which he was mentioned in despatches.

Under instructions from the Horse Guards, the under-mentioned officers of the Army Medical Staff, whose tour of foreign service will expire during the trooping season of 1895-96, will proceed to England and will be detailed by the principal medical officer, Her Majesty's forces in India, for duty with troops on the homeward voyages. Medical officers requiring passage for their families should apply to the general officer commanding the district in which they are serving, who will arrange with the other commanding at the port of embarkation for allotment of the authorised accommodation in the troopship to which they will be detailed.

Punjab Command.—Brigade-Surgeon-Lieutenant-Colonel H. T. Brown, M.D.; Surgeon-Lieutenant-Colonel G. Corry (in exchange with Surgeon-Lieutenant-Colonel J. McNamara); W. Denovan and G. T. Langridge; Surgeon-Majors N. Leader, H. E. W. Barrington, T. B. McGuff, G. E. A. Smythe (in exchange with Surgeon-Major J. F. Williamson), and J. Harman. W. Dugdale (in exchange with Surgeon-Major R. E. R. Morgan, who exchanged with Surgeon-Major J. G. MacNicol); L. W. Swabey, and T. E. Noding (in exchange with Surgeon-Major C. A. Webb).

Bengal Command.—Brigade-Surgeon-Lieutenant-Colonel M. Knox and A. A. Macrobain, M.B.; Surgeon-Lieutenant-Colonel R. M. Mennerick; Surgeon-Majors W. Keays, H. A. H. Charlton, J. Watson, M.D., A. O. G. Leitch, M.D., A. P. Hart, M.B. (in exchange with Surgeon-Major J. L. Peyton, who exchanged with Surgeon-Lieutenant-Colonel H. Stannard) and E. Butt; Surgeon-Captains E. G. Browne and J. W. Bullen, M.D.

Madras Command.—Surgeon-Lieutenant-Colonel J. Martin (in exchange with Surgeon-Major W. P. Feltham); Surgeon-Majors I. B. Emerson, A. W. Carleton, M.B. (in exchange with Surgeon-Major J. R. Dodd), W. T. Johnson, M.D., R. O. Cusack, W. D. A. Cowen, G. W. Robinson, G. F. Poynder, and C. R. Woods, M.D.; Surgeon-Captains M. Kelly, M.D., R. J. D. Hall (in exchange with Surgeon-Captain E. O. Wright), J. W. Cockerell, and W. L. Gray, M.B.

Bombay Command.—Surgeon-Lieutenant-Colonel R. H. Quill, M.B.; Surgeon-Majors E. H. Myles, M.B. (in exchange with Surgeon-Major J. C. Culling), A. E. J. Croft, E. L. Maunsell, R. F. Adams, M.B., C. G. D. Mosse, J. Macoschie, and T. A. Dixon.

It is really to be hoped our correspondent is mistaken, as it could scarcely pay any practitioner to give his services at this rate. In cases of this kind it is usually found that it is "the poverty and not the will" of the practitioner that consents to such miserable payment, so it is difficult to conceive that anything of the kind could be done by a responsible practitioner in any circumstances.

B.—Our correspondent, having omitted to communicate his name, we are constrained to defer a reply until he has conformed to our essential and invariable rule.

PROFESSIONAL ADVERTISING.

DR. RICHARD P. LONG (99, Queen's Crescent, Haverstock Hill, N.W.) writes: As I am neither directly, nor indirectly, responsible for the paragraph in the *St. Pancras Gazette* (see *BRITISH MEDICAL JOURNAL*, September 21st, p. 769), I hasten to inform you of the fact. People who know me are well aware that I am in no need of advertisement, and that to do so would be both reprehensible and superfluous. In conclusion, I may add, that as a member of the *St. Pancras Vestry*, and consequently a public man, I am as powerless to restrain the local press from recording my movements as I am to prevent them from criticising my votes.

TOUTING SOCIETIES AND PERSONAL ADVERTISEMENT.

JUAN DE F.—The London and Manchester Assurance Society does, we believe, carry on a system of "touting," so that we cannot recommend our correspondent to accept office in it; he may be quite sure his brother practitioners in his neighbourhood will look askance at him, if agents of a society of which he is one of the medical officers, endeavour to entice away their patients for his benefit.

With regard to the labels referred to, they are discreditable to the persons whose names they bear, and afford a striking proof of how practices of this kind are made use of for purposes of advertising. We print one of these as an example of what a medical man ought not to do.

LONDON AND MANCHESTER INDUSTRIAL INSURANCE SOCIETY.

DR. A. SHAW-MACKENZIE,

Physician and Accoucheur,

Fell. Brit. Gynaecol. Soc.,

"Danehurst," 3, Barclay Road, Fulham Road,
(Near Broadway, Waltham Green.)

Hours: 9 to 11 A.M. and 7 to 9 P.M., Sundays Excepted.
Messages for Visiting to be left before 11 A.M.

All Members on Dr. MACKENZIE'S List are entitled to Medical Aid immediately on joining the Society.

A reduced fee for Confinements is charged to Members, which may be paid by instalments if desired, but all payments must be completed previous to attendance on the case.

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF DURHAM.

SECOND EXAMINATION FOR THE DEGREE OF BACHELOR IN MEDICINE.
—The following candidates have satisfied the examiners:

Anatomy, Physiology, Materia Medica.—First Class Honours: G. G. Turner, College of Medicine, Newcastle-upon-Tyne; E. G. E. Arnold, M.R.C.S., L.R.C.P., St. Thomas's Hospital. Second Class Honours: V. Burrow, St. Mary's Hospital; R. F. Moorhead, Bristol Medical School; T. Streetfield, M.R.C.S., L.R.C.P., University College Hospital, London; H. C. Coxon, College of Medicine, Newcastle-upon-Tyne. Pass List: J. E. Baker, College of Medicine, Newcastle-upon-Tyne; F. A. Cooke, College of Medicine, Newcastle-upon-Tyne; W. W. Deans, Yorkshire College, Leeds; C. E. Fern, King's College; J. M. Gover, College of Medicine, Newcastle-upon-Tyne; C. Johnson, College of Medicine, Newcastle-upon-Tyne; R. A. R. Lankester, University College Hospital, London; W. H. Lister, College of Medicine, Newcastle-upon-Tyne; W. B. Milbank, College of Medicine, Newcastle-upon-Tyne; G. W. Middlemiss, College of Medicine, Newcastle-upon-Tyne; F. Pope, Mason College, Birmingham; H. C. Reguart, Guy's Hospital; B. C. Stevens, St. Thomas's Hospital.

OBITUARY.

PROFESSOR FRIEDRICH MIESCHER.

DR. MIESCHER, the Professor of Physiology in Bale, died at Davos on August 26th. To Davos he went in the hope of recovering from a severe pulmonary affection, which was, however, tuberculous in its origin and proved fatal. Miescher was born in Bale on August 13th, 1844, so that he was only 51 at his death. He studied at Bale, and in 1867 became Doctor of Medicine. His bias, however, was towards natural science—a bias strengthened by the example of his father and by his uncle and teacher Professor His.

From an early period he devoted himself to the study of physiology, and as his father had been a pupil of Johannes

Müller, so Miescher early learned to regard the great master as his ideal, and it was ever his wish and endeavour to follow in his footsteps. About this time the Leipzig School of Physiology under C. Ludwig was the great centre of physiological investigation, and thither Miescher went.

Under the inspiration of Ludwig, Miescher studied the course of sensory impulses in the spinal cord, and in Ludwig's *Arbeiten* (V, 1870) has published "Zur Frage d. sensiblen Leitung im Rückenmark." But Miescher's bias lay rather in the investigation of chemical problems, so that he perfected his chemical knowledge under Hoppe-Seyler, who was then in Tübingen; and he also spent some time in Strecker's laboratory. As the result of his work in Tübingen he published the discovery of a new phosphorus-containing body—nuclein, which forms the chief part of the cell nuclei. In 1871 Miescher began as *Privat-docent* of Physiology in Bale. When Professor His in 1872 was called to Leipzig to the Chair of Anatomy there, Miescher became Professor of Physiology in Bale, a post which he held until his death. In the head of spermatozoon he discovered a new organic base—protamin. This research led him to the study of the life-history of the Rhine salmon. The salmon pass from the sea to the fresh water of the Rhine, where they remain several months, but during all the time of their sojourn in fresh water Miescher found that they took no food. Nevertheless, during all this time, the reproductive organs developed enormously, increasing in weight over 100 times. Miescher succeeded in explaining how, in spite of the absence of food, the development of the reproductive organs took place at the expense of other organs, especially the muscles. In later years he studied the relations of the respiratory and circulatory systems. In 1893 he sought to explain the rationale of the restorative effects of a sojourn at high altitudes. Miescher was much beloved by his pupils, and to all of them he was the type of a noble, true, and unselfish friend. He is succeeded in the Chair of Physiology by his friend and pupil R. Retzner, who lectured for him during the last year of his professorship, when he was too weak to continue to fulfil the duties of the office.

PROFESSOR BARDELEBEN.

A RUTHER telegram from Berlin announces that Professor Bardeleben, the eminent surgeon, died there on September 24th, at the age of 76. Professor Bardeleben was born at Frankfurt-on-the-Oder in 1819. He received his medical education in Berlin, Heidelberg, and Paris, and after some years spent as assistant and professor at Giessen and Griefswald was, on the outbreak of war in 1866, appointed Surgeon-General, acting as consulting surgeon to the field hospitals of the Gitchin district. In 1868 he became Professor of Surgery in Berlin University. When the Franco-Prussian war broke out Professor Bardeleben again took the field, being attached to the First Army Corps as consulting surgeon. For his services he was created Surgeon-General *à la suite*. His literary fame rests principally upon his *Lehrbuch der Chirurgie und Operationslehre*, which was at once accepted as a standard work both at home and abroad.

We regret to have to record the death of Surgeon-General JOHN IRVINE, M.D., Honorary Physician to the Queen, who died in Kensington on September 21st. Dr. Irvine graduated M.D. of Aberdeen University in 1849, and in the same year obtained the qualification of L.R.C.S. Edinburgh. He entered the Army Medical Department as Assistant-Surgeon in 1850. He served throughout the operations with Havelock's column in 1857 in medical charge of the Royal Artillery (Maudslayi), and was present at a number of actions and at the relief of Lucknow, being mentioned in despatches. He was with Outram's force in the Alumbagh from November, 1857, to March, 1858, and at the siege and capture of Lucknow by Lord Clyde. He was awarded in this connection the medal with two clasps and a year's service. He also received a medal with clasp for service with the Burmah expedition in 1886. In 1869 he was promoted to be Surgeon-Major, and he became Deputy Surgeon-General in 1876, and Surgeon-General in 1883. He was appointed Honorary Physician to the Queen in 1885, and was placed on the retired list of the army in 1888.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns, including London, 6,378 births and 4,668 deaths were registered during the week ending Saturday, September 21st. The annual rate of mortality in these towns, which had been 19.9 and 19.3 per 1,000 in the two preceding weeks, rose again to 10.8 last week. The rates in the several towns ranged from 4.1 in Croydon, 12.3 in Plymouth, and 14.8 in West Ham, to 30.5 in Salford, 31.8 in Hull, and 32.9 in Sunderland. In the thirty-two provincial towns the mean death-rate was 2.4 per 1,000, and exceeded by 6.5 the rate recorded in London, which was only 10.6 per 1,000. The zymotic death-rate in the thirty-three towns averaged 4.8 per 1,000; in London the death-rate did not exceed 2.7 per 1,000, while it averaged 6.3 in the thirty-two provincial towns, and was highest in Sunderland, Salford, Blackburn, and Burnley. Measles caused a death-rate of 2.2 in Oldham, and 2.9 in Blackburn; whooping-cough of 1.9 in Sunderland, and 2.7 in Gateshead; "fever" of 1.2 in Blackburn, 2.1 in Derby, and 4.2 in Sunderland; and diarrhoea of 7.2 in Sunderland, 7.4 in Salford, 8.6 in Blackburn, 9.1 in Hull, and 9.4 in Burnley. The mortality from scarlet fever showed no marked excess in any of the large towns. The 65 deaths from diphtheria in the thirty-three towns included 37 in London, 4 in West Ham, and 4 in Burnley. Two fatal cases of small-pox were registered in London, and 1 in Oldham, but not one in any other of the thirty-three large towns. There were 271 cases of small-pox under treatment in the Metropolitan Asylums Hospitals and in the Higgate Small-pox Hospital on Saturday last, September 21st, against 261, 264, and 277 at the end of the three preceding weeks; 33 new cases were admitted during the week, against 38, 25, and 49 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had increased from 2,597 to 2,674 in the four preceding weeks, had further risen to 2,732 on Saturday last, the 21st inst.; 341 new cases were admitted during the week, against 294, 399, and 385 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

DURING the week ending Saturday, September 21st, 881 births and 634 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 17.5 and 18.9 per 1,000 in the two preceding weeks, rose again to 18.5 last week, but was 1.3 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 10.3 in Perth to 23.5 in Greenock. The zymotic death-rate in these towns averaged 3.2 per 1,000, the highest rates being recorded in Greenock and Dundee. The 262 deaths registered in Glasgow included 19 from diarrhoea, 9 from "fever," 6 from whooping-cough, and 2 from diphtheria. Three deaths were referred to "fever" in Greenock.

THE EAST LONDON WATER INQUIRY.

IT is to be hoped that in the inquiry which is about to be held in regard to the deficiencies of the East London water supply sight will not be lost of the great danger which accrues to the public from an intermittent supply when the pipes are leaky. It has been stated, as an excuse for cutting off the water for many hours a day, that there were 50,000 leaky pipes, and that many of these were underground. Now, as a matter of mere health, so far from this being an excuse for intermittency of supply, it is the very reason for keeping it constant. We know what the subsoil of London is, and how it is permeated in every direction by drains that are far from faultless; and it should never be forgotten that every pipe that leaks into the subsoil when the pipes are full sucks in the puddle so produced whenever the pipes are empty. The existence of a leak is a good reason for cutting off the supply entirely until it is mended, a stoppage being provided in the meantime, but it is no excuse for giving an intermittent supply by which at any moment typhoid poison may be sucked into the mains, and epidemics may be produced in East London as they have again and again been produced in other places from exactly the same cause.

THE NEGLECT OF VACCINATION IN LONDON.

WE commented last week upon the finding of a "Public Health Critic," who could discover in the recently issued report of the Medical Officer of the Local Government Board nothing but "five hundred pages of microscopic portents." It is a welcome relief to turn from the absurdities of this critic to an article which recently appeared in the *City Press*, in which attention is drawn to some very important statements made in the annual report in question. The writer of the article in the *City Press* refers to the growing neglect of vaccination in London, and quotes from the medical officer's report the statement that the percentage of infants finally unaccounted for in London has risen from 3.7 in 1881 to 14.4 in 1891; the corresponding figure in 1891 for the provinces being 1.9 per cent. The percentage in question in London is 3.7, and is true for the case of such towns as Leicester, Nottingham, and Bedford. The importance of so considerable an extent of neglect among the huge aggregation of persons in the metropolis cannot, however, be overestimated, and our contemporary does indeed serve by drawing the attention of its readers to what we quite agree in regarding as "one of the most serious statements" in the annual report of the medical officer of the Local Government Board.

UNVACCINATED CHILDREN IN LONDON.

THERE is a passage in the Report of the Medical Officer of the Local Government Board which deserves particular attention, in view of the prevalence of small-pox in London in districts where vaccination is

much neglected. It appears that nearly 17 per cent. of the children born in the metropolis are now unprotected by vaccination, a very large increase indeed. The law seems to have become pretty nearly a dead letter, and the reason assigned is instructive. It began to be generally set at naught in 1889, and that was the year when the Royal Commission on Vaccination was appointed. This has largely been interpreted as a practical admission that the value of vaccination is an open question, and has had the effect of making local authorities reluctant to enforce the law.

MEDICAL NEWS.

THE next meeting of the German Association of Naturalists and Physicians will be held at Frankfurt.

PROFESSOR E. A. SCHÄFER, F.R.S., has been nominated as one of the General Secretaries of the British Association for the Advancement of Science.

THE Viennese Medical Council has adopted a resolution condemning strongly the resort to advertisement by medical men.

THE metric system will become the sole legal system of weights and measures in Mexico on and after September 16th, 1896.

THE prizes of St. Thomas's Hospital will be distributed in the Governors' Hall at the hospital by Sir Edwin Arnold, K.C.I.E., O.S.I., on October 2nd, at 3 P.M.

THE introductory lecture at the Royal Veterinary College will be delivered by Professor Penberthy, F.R.C.V.S., on Wednesday, October 2nd, at 1 P.M.

VACCINATION GRANT.—Dr. Fred. W. Lewis, Public Vaccinator of the No. 1 district, Llandovery Union, has received the Government grant for efficient vaccination for the eighth time.

THE opening of the winter session at the University of Durham College of Medicine will take place on Tuesday, October 1st, when the prizes and scholarships will be distributed by the Very Rev. the Dean of Durham, Warden of the University.

THE fifth Congress of the German Dermatological Society was held in Graz from September 28th to September 29th. The first discussion was on pemphigus, and was opened by Professors Kaposi (Vienna) and Rosenthal (Berlin). The second day of the Congress was devoted chiefly to questions connected with the treatment of syphilis, and the third to demonstrations.

NEW FEVER HOSPITAL FOR EDINBURGH.—At a meeting of the Edinburgh Town Council on September 24th the Public Health Committee recommended the purchase of the farm of Colinton Mains, at a cost of £20,500, as a site for a hospital for infectious diseases. The site had been reported on favourably by Sir Henry D. Littlejohn and the City Superintendent of Works.

CHARGE OF MANSLAUGHTER.—Dr. George Wight, of Hol-loway, was brought up on a charge of manslaughter before the magistrate at Clerkenwell on September 25th. The charge arose out of the death of a woman after childbirth which had been the subject of a coroner's inquiry at Finsbury, concluded on the previous day, when a verdict of manslaughter was returned. It is alleged that Dr. Wight was under the influence of a narcotic at the time he attended the deceased woman.

CONGRESS OF POLISH SURGEONS.—The seventh Congress of Polish Surgeons was held at Oracow on July 16th and 17th, under the presidency of Professor Rydygier of that University. There was a large attendance of practitioners from different parts of Poland and Galicia and a sprinkling of foreigners. Among the communications were papers by the President on a Modification in the Procedure of Resection of the Pylorus, and on the Treatment of Actinomycosis; by Dr. Th. Drobnik, on the Operative Treatment of Cysts of the Pancreas, etc. Dr. Jasinski showed five patients on whom laminectomy had been performed; Dr. Stepinski showed eight cases in which the skull had been trephined; and Professor Obalinaki presented a female patient from whose brain he had removed a tumour.

MEDICAL VACANCIES.

The following vacancies are announced:

- BETHLEM HOSPITAL.**—Two Resident Clinical Assistants; doubly qualified, appointment for six months. Apartments, salaries, and attendance provided. Applications, endorsed "Clinical Assistant," to the Treasurer at Bethlem Hospital before October 1st.
- BIRMINGHAM AND MIDLAND EYE HOSPITAL.**—Assistant House-Surgeon. Salary and per annum, with apartments and board. Applications to the Chairman of the Medical Board by September 30th.
- BRIGHTON THROAT AND EAR HOSPITAL, 23, QUEAN'S ROAD, BRIGHTON.**—Non-resident House-Surgeon. Salary at the rate of £20 per annum. Applications to the Secretary by September 30th.
- CARNARVON JOINT SANITARY DISTRICT.**—Medical Officer of Health, must be between 25 and 40 years of age, doubly qualified. Must devote his whole time to the duties, and have a knowledge of the Welsh language. Appointment for five years. Salary, £204 per annum, inclusive of all expenses, except those incurred for such books, stationery, and apparatus required in the performance of the duties. Applications, endorsed "Application for Office of M.O. Health," to J. H. Thomas, Clerk, to the Joint Committee, 34, Market Street, Carnarvon, by October 15th.
- COUNTY OF BRECON.**—County Analyst. Retaining fee, £10 10s, and a fee of 10s. 6d. for the analysis of every sample. Applications to H. Edgar Thomas, Clerk to the County Council, County Hall, Brecon, by October 2nd.
- EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, GLAMIS ROAD, SHADWELL, E.**—Assistant Physician to see out-patients. Must be Fellow or Member of the Royal College of Physicians of London. Applications to Thomas Hayes, Secretary, by October 1st.
- EXETER AND COLCHESTER HOSPITAL.**—House-Surgeon, doubly qualified, salary, £200 per annum, with board and lodging in the hospital. Applications to the Committee by October 15th.
- GALWAY HOSPITAL.**—Resident Medical Officer. Appointment tenable for six or twelve months. Board, lodging, fire, light, and washing provided. Applications and testimonials to the Registrar, Galway Hospital, by October 3rd.
- GLASGOW MATERNITY HOSPITAL.**—Obstetric Physician and Assistant. Salary, £200 per annum. Applications to Arthur Forbes, Secretary, 140, Buchanan Street, Glasgow, by November 25th.
- HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.**—Resident House-Physician. Applications and testimonials to W. Theobald, Secretary, by October 10th.
- LONDON FEVER HOSPITAL, LIVERPOOL ROAD, ISLINGTON, N.**—Assistant Resident Medical Officer. Salary, £120 per annum. Applications to the Committee by October 1st.
- LONDON HOSPITAL, WHITECHAPEL, E.**—Medical Electrician, must be qualified and registered under the Medical Act. Applications to G. Q. Roberts, House-Governor, by October 15th.
- METROPOLITAN HOSPITAL, KINGSLAND ROAD, N.E.**—Assistant Surgeon. Must be Fellow of the Royal College of Surgeons of England. Applications and testimonials to Charles H. Byers, Secretary, by October 7th.
- NORFOLK AND NORWICH HOSPITAL.**—Dispenser; must be registered Pharmacist. Salary, £100. Applications to the Secretary by October 1st.
- PARISH OF DURNES, SUTHERLANDSHIRE.**—Medical Officer. Guaranteed salary, £150 per annum, with practice, free house, and garden. Applications to Robert Sutherland, Inspector of Poor, Durness, by October 15th.
- PARISH OF ST. MARY, ISLINGTON.**—Resident Assistant Medical Officer for the Workhouse and Infirmary. Salary, £200 per annum, with rail fares, apartments, and washing, or an allowance in lieu of same. Applications to Edwin Davey, Clerk, by October 8th.
- ROTHERHAM HOSPITAL AND DISPENSARY.**—Assistant House-Surgeon. Doubly qualified, and registered. No salary; board, lodging, and washing. Applications and testimonials to the House-Surgeon by October 1st.
- ROYAL ALEXANDRA HOSPITAL FOR RICK CHILDREN, DYKE ROAD, BIRMINGHAM.**—House-Surgeon, doubly qualified. Salary, £200 per annum, with board, lodging, and washing, in the hospital. Applications to the Chairman of the Medical Committee by October 4th.
- ROYAL FREE HOSPITAL, GRAY'S INN ROAD, W.C.**—Resident Medical Officer (House-Physician); doubly qualified. Appointment for six months but eligible for re-election. Board, residence, and washing provided. No salary. Applications to the Secretary by October 1st.
- SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.**—Junior Surgeon. Applications to the Honorary Secretary, J. A. Simpson, Solicitor, South Parade, Nottingham, by October 1st.
- SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.**—House-Surgeon. Salary, £200 with board and residence. Applications and testimonials to J. Walter Wilson, Honorary Secretary, by October 15th.
- SUSSEX COUNTY HOSPITAL, BRIGHTON.**—Assistant House-Surgeon, doubly qualified, unmarried, and when elected under 30 years of age. Salary not exceeding £50 per annum, with board, washing, and residence in the hospital. Applications to the Secretary by October 2nd.

MEDICAL APPOINTMENTS.

BAYMAN, DR., appointed Medical Officer for the Workhouse and the Walsingham District of the Walsingham Union, vice F. W. B. yes, M.R.C.S.Eng., L.S.A., resigned.

- DENDLE, Frank, M.B., C.M. Edin.**, appointed Medical Officer for the Glenaig Colliery.
- DOIDGE, M. J., B.A. Camb., M.R.C.S. Eng.**, appointed Medical Officer for the No. 3 District of the Wells Union.
- FOSTER, WILLIAM, B.A., M.B., D.P.H. Camb., M.R.C.S. Eng.**, appointed Medical Officer of Health for the Wemyss Urban District, vice J. J. Hetherford, M.D. St. And., L.R.C.P. Edin.
- FOX, J. A., L.R.C.P. Lond., L.R.C.P. Edin., L.R.C.S. Edin., L.F.P.S. Glasg., L.S.A. Lond.**, appointed Medical Officer and Public Vaccinator for the No. 1 District and Workhouse, Popnange Union, vice A. W. T. Steer, M.R.C.S. Eng., L.R.C.P. Lond., resigned.
- GADMAN, J. C., L.R.C.P., L.R.C.S.**, appointed Medical Officer and Public Vaccinator for the No. 3 (Warblaton) District of the Hallowham Union, vice R. Clarke, M.R.C.S. Eng.
- GERVAN, David W., M.B., C.M. Glasg.**, appointed Medical Officer for the Third South District of the Carden Union, vice A. Rees, L.R.C.P. Lond., M.R.C.S. Eng., resigned.
- GORDON, WILLIAM, M.B.**, appointed House-Surgeon to the Salisbury Infirmary, vice E. L. Wilton, resigned.
- HELBY, E. H., M.R.C.S., L.B.C.P., D.P.H.**, appointed Resident Medical Officer to the Croydon Borough Hospital.
- MACDONALD, James, M.A., M.B., C.M. Edin.**, appointed Medical Officer of Health for the Carlisle Rural District, vice J. S. Hall, M.R.C.S. Eng., deceased.
- MACGREGOR, Duncan A., M.B., C.M. Edin.**, re-appointed Medical Officer of Health to the Clapton West Urban District Council.
- MACINTYRE, H., M.B., C.M. Glasg.**, appointed Senior Assistant Medical Officer to Shoreditch Infirmary, vice P. J. Probyn, M.R.C.S., L.R.C.P., resigned.
- MASON, Arthur H., L.R.C.P. Lond., M.R.C.S. Eng.**, appointed Medical Officer for the Walton and Outlands District of the Chertsey Union, vice G. W. Drabbie, M.A., M.B., B.C. Camb., resigned.
- MATTHEWS, DR.**, appointed Medical Officer for the Sixth District of the Mansfield Union, vice W. A. Stamford, M.R.C.S. Eng.
- PARR, J. W., M.D., C.M. Edin., L.D.S.**, appointed Lecturer on Dental Anatomy and Physiology to the National Dental Hospital, vice Sidney Spokes, M.R.C.S., L.D.S., resigned.
- SHARP, DR.**, appointed Medical Officer for North Marine.
- WALKER, Allan, M.B., C.M. Glasg.**, appointed Medical Officer of Health for the Westslade Urban District.
- WARD, Francis, M.B., C.M. Edin.**, appointed Second House-Surgeon to the East Suffolk Hospital, Ipswich.
- YELF, Robert, M.B., C.M. Edin.**, appointed Medical Officer and Public Vaccinator for the Norton District of the Shipston-on-Stour Union, vice L. K. Yelf, M.D. St. And., resigned.

DIARY FOR NEXT WEEK.

TUESDAY.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 2 P.M. Lecture at 4.

WEDNESDAY.

OBSTETRICAL SOCIETY OF LONDON, 5 P.M.—Specimens will be shown by Dr. Duncan and others. Papers:—Dr. T. G. Stevens and Dr. Griffith: Notes on the Variation in Height of the Fundus Uteri above the Symphysis during the Puerperium, the Conditions which Influence this, and the Practical Conclusions which may be drawn from such Observations. Dr. G. D. Robinson: On Certain Micro-organisms of Obstetrical and Gynecological Interest.

FRIDAY.

WEST KENT MEDICO-CHIRURGICAL SOCIETY, Greenwich, 8.15 P.M.—The "Purvis Oration" on Changes in Medical Examinations and Education—a personal retrospect, by Professor John Curnow, M.D.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 2s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

- MCMAULAY.**—On September 15th, at Haylake, Cheshire, the wife of Matthew McAulay, M.D., of a son.
- POWER.**—September 22nd, at 3, Hoe Park Terrace, Plymouth, the wife of Surgeon Major E. R. Power, Army Medical Staff, of a daughter.

MARRIAGES.

- LAW-PRIKLER.**—On September 16th, at St John's Church, Blindley Heath, Surrey, by the Vicar, the Rev. F. G. Doodes, Robert Redman Law, B.A., M.B., B.C. Camb., of The Maple Sidcup, son of the late R. H. Law, Esq., of Haslington, York, to Ada Mary, eldest daughter of William Priker, Esq., of Godstone, Surrey.
- POLLARD-GILBERT.**—On September 16th, at Felstead, Walter H. Pollard, M.B., of Tollesbury, Essex, to Ethel Maude, daughter of the late Joseph Gilbert, of Charlbury.

DEATHS.

- STACEY.**—August 21st, at Durban, Port Natal, William Henry Waterhouse Stacey, M.R.C.S.Eng., L.R.C.P. Edin., recently of Grimsby, King's Lynn, only surviving son of the late William Stacey, of Holly Lodge, Newmarket Road, Norwich, in his 33rd year.
- TYLSCOTE.**—On September 16th, at Haywood, Staffordshire, Edward Thomas Tylscote, M.D., aged 65.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 42, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 42, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 42, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should communicate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUESTIONS.

STRETCHER wishes to know if any member can inform him where an articulated skeleton could be hired for use at two or three courses of lectures in connection with the St. John Ambulance Association.

MEMBER would be glad to know if the third toe being overlapped by the second toe would disqualify a boy in the medical examination for a clerkship in the Royal Navy. If so, would he be eligible if the toe was straightened by operation?

DR. HARRY CAMPBELL (20, Devonshire Street, Portland Place, W.) writes: I should be greatly obliged if any of your readers could give me instances (1) of an individual enjoying better health after an illness than before, (2) of one disease diminishing the intensity of, or actually removing, another disease.

L. W. asks if there is any institution where the sons of a medical man in adverse circumstances can be educated at reduced terms. The children are under eight years, and consequently ineligible for Epsom College.

NAME asks for a list of books to be read for the First Examination of the F.R.C.S. Eng. by an M.R.C.S. L.R.C.P. Lond.

*. If our correspondent took his qualifications within the last ten or twelve years, we advise him to make use of the books which he studied for the membership examination. If he were qualified many years since he should consult the present teachers at his medical school. It is useless to attempt to pass the primary examination for the Fellowship on book study alone.

TAMM writes: Can any reader advise in the following matter? A bill, strictly made up according to the scale of fees recommended in the *Medico-Chirurgical Tariff*, is refused on the plea that the charges are too high. The patient belongs to the former class, and is in very comfortable circumstances, but expects to be charged at the same rate as the working classes. The fees charged are the same as those in the lowest scale in the *Tariff*—namely, on a rental of £30 per annum. Has any reader used according to the fees in the *Tariff*, and can this be looked upon as an authority in the question of fees?

ECZEMA AT THE SEASIDE.

F. P. writes: We have always been taught that cases of eczema do badly at the seaside. But is this really so? I have lately had an obstinate case of eczema of the face and scalp which went to the sea (against my advice), and came back in two months nearly cured, no treatment having been used there.

FLIES-BITES.

CLINIC writes: A lady is a constant victim to fleabites. The house in which she resides with her family and servants is clean and in good repair; no other member of the household ever suffers the same inconvenience in the slightest degree. If she but enter a railway carriage or omnibus, or careen a dog or cat, or pass near a manure pile, ending in the discovery and annihilation of the marauder. The following remedies have already been tried: Carbolic baths, sulphur inunction, naphthalene sachets, but all to no purpose. As this selective persecution is becoming a serious irritation to an already nervous individual, I should be grateful for suggestions.

INLAND REVENUE

HARD LINDS writes as follows: I have recently entered into partnership with my late partner. Am I liable to pay taxes for a manservant and a cart for this year, although my late partner has already paid for

them? With the half share of the practice I have bought two ponies and a cart.

*. If we understand the question correctly, we think our correspondent is liable to pay the taxes in question. Licences to keep a male servant or carriage cannot be transferred to any person other than the widow or legal personal representative of the person to whom such licence was originally granted. In this case our correspondent has purchased the cart or carriage, and we gather also that he now employs and pays the manservant.

ANSWERS.

NAME (Harrogate).—Unless the patient be certifiable as insane, she can be sent to, and detained in, a retreat only with her own consent.

BULL'S EYE.—Steam broughams are at present subject to the same restrictions as to the use of bridges, etc., as traction engines. The Government is understood to be pledged to introduce a short Bill next session to modify the law in this respect.

A. C.—We advise our correspondent to apply to the Secretary of one of the Colleges (Physicians or Surgeons) in the United Kingdom. The case is exceptional, but we doubt if any examining body is empowered to admit a candidate to its qualifying examination when he has passed the elementary professional examinations elsewhere. The case is quite different from that of the candidate who has passed in "Arts" as a preliminary subject. He is thereby qualified to offer himself as a candidate before several well-known examining boards without any fresh "Arts" examination.

PSYCHOLOGY AND THE M.D. LOND.

X. writes: In answer to M. B. Lond., who wishes to read for the London M.D., to refer him to Hyslop's *Mental Physiology*, which is adapted to the requirements of this examination. There are also the following well-known works: Professor Laist's *Physiological Psychology*, Professor James's *Principles of Psychology*, Professor Sully's *Outlines of Psychology*.

NOTES, LETTERS, Etc.

ERRATUM.—Mr. D'Arcy Power asks us to state that "Scelopody" in the title of his paper, published in the BRITISH MEDICAL JOURNAL of September 21st, was a misprint for "Scelopody."

A WARNING.

VICTIM writes: A short, shabbily-dressed, bearded man, aged about 30, and dark, is calling upon medical men in Newcastle-on-Tyne and neighbourhood soliciting books (unbound) for binding, and asking for part payment "in advance." Although feeling certain I was about to be duped I advanced money a few months since, and, of course, I have neither seen books nor money. He calls himself Watson, but must not be confounded with the *bona-fide* bookbinder of that name, William Watson, of High Friar Street, Newcastle. To-day I hear he has taken in several other doctors.

A CURIOUS FOULTIE.

M.R.C.P. writes: I am surprised at several letters re the above, and alluding to dung poultices as a novelty. For years past they have been generally used in many parts of England, and serious results sometimes follow the application of cow or other animal dung to abraded surfaces. Of one case, occurring in Warwickshire some years ago, I have a vivid remembrance; a child having broken its chin, the wise woman of the locality was consulted; she advised a sheep's dung poultice. A few days after the application blood poisoning followed, and the child died. The late Mr. S. Cox, of Birmingham, visited the case in consultation, and it was afterwards ascertained that the sheep from which the dung was procured had the disease known as "the rot," the animal having liver flukes no doubt in an advanced stage of the disease.

"MEDICAL BOOK-KEEPING."

DR. W. WRIGHT HARDWICK (East Molesey) writes: Permit me to draw the attention of members of the profession to an addition made to my system of medical book-keeping. A want was felt that some means of making notes on cases ought to be provided, but it was impossible to make this addition to the book itself without great additional expense in interleaving and increasing the size unduly. To meet the requirement and to obviate the difficulty I have designed "memoranda leaves," alphabetically arranged to correspond with the first and last pages for temporary insertion on each month. At the end of the month these are placed in a box for and from which inserted, so that a record of each case can be found in a moment. The dates, which follow each other successively, and the names are arranged in columns at the end of each page with printed headings, so that in referring it is only necessary to turn over the pages in the same manner as the pages of a book is sought for. The "leaves" are secured by a horizontal in sufficient number to last the six years that the book lasts, and each box thus contains the notes of all cases during that period. They can be obtained bound as a separate volume, but the loose leaves are more convenient in a busy practice.

A MEDICAL AUTHOR.

A FEW years ago Dr. Max Simon Norden was, says the *Echo*, comparatively speaking an unknown quantity, but now as the author of *Immunisation* he has acquired a name throughout the world that only a few can claim. Dr. Norden is of Jewish parentage and was born July 24th, 1849, in Ruda-Pesth. In 1872 he took his doctor's degree at the University in his native city. After travelling from the University north to the Russian South, he settled down as a medical practitioner at Ruda-Pesth, and remained there until 1880, when he removed to

Paris, where he has since lived engaged in the practice of his profession. Dr. Nardau has been a voluminous writer. He commenced his literary career in connection with the press, editing in turn the *Feuille de la République*, the *Journal de la République*, and the *Journal de la République*. His first book was entitled *Paroles de Nardau*, and it mainly consisted of criticisms of social and political conditions. He subsequently published a volume of short stories, a study in social pathology, four novels, four comedies, and four dramas. His works on *Insurrection*, *Paradoxes*, and *Constitutional Life of Society* have been translated into the English language.

THE BENEDICTION OF MERCURY.

MR. C. R. ILLINGWORTH (Venetian, L.W.) writes: For many years I have striven to point out the value of the bismuthide as a germicide and destroyer of toxins, but with little success compared with what should have been the result. It only remains for me to give cases as they occur. A little girl was stung on the neck by a wasp two days ago. The bismuthide (1 in 500) was applied, and in two hours the redness, swelling, and pain, which were considerable, had completely subsided. The action invariably acts in this rapid manner in all poisoned wounds.

EROSION OF THE TEETH IN CHILDREN.

MR. SIDNEY SPOKES, M.R.C.S., L.D.S. (Queen Anne Street, London) writes: May I be allowed to correct the remarks attributed to me in the BRITISH MEDICAL JOURNAL of September 21st, page 711. Dr. Barton read a paper on "Erosion." I tried to point out that this term, borrowed from the Continent to describe the condition of the teeth he discussed, was a bad one, not only because, even according to the paper, the cause was not due to erosion, but also because the same term is applied by English dentists to a totally different lesion.

Again, I was unable to say that I was not prepared to hear that 2½ per cent. of children had their permanent teeth affected. What I did say was that my own observations of children's mouths inclined me to agree with the 5 per cent. mentioned in Dr. Barton's paper.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE TITLE OF "DR." CHAGIN writes: I am a Licentiate of the Royal College of Physicians of London. I came to E— as an assistant, my principal put me up a plate "Dr." Eventually I bought up my bond and started in practice on my own account. I did not dare to change the wording of my door plate. Five years after my starting for myself the Royal College of Physicians demand that I shall alter my door plate. I find I had signed a law bearing on this point, so I immediately obey their orders. Though, so very careful have I always been to cultivate the best class of practice, that I have never taken any club or such-like appointments. I have not even indulged in a red lamp. Nevertheless, my former principal who lives only eight doors away from me put "Dr." on his plate apparently without hindrance. He is L.R.C.P. Edin., L.M., only. In this neighbourhood are many Scotch and Irish licentiates, all of whom do the same as my former principal does.

CARBOLIC ACID POISONING.

MR. A. W. SHEPHERD (Cambridge) writes: The case with which this poison can be obtained, and its cheapness, I presume, accounts for the number of cases we read of in which persons have ended their lives by swallowing it. It appears strange that no antidote is given for it in books. Reaction is made of using oil, and on a chemist's label I read "in cases of poisoning give large doses of olive oil and white of egg." Now I can quite see the good of oil, but especially of the egg to allay the pain in mouth, but I should be sorry to give large doses of oil, my reason being that I always thought carbolic acid was very soluble in oil, consequently I should only hasten death. I remember a case of a gentleman asking for a black draught in a country chemist's, and quickly swallowed what was handed him; at once he said "It is carbolic I have taken." Oil, and, I think, glycerine were given, with the result he died. Now, if the chemist had only given, instead of the oil, a strong solution of magnesia or soda sulphate, the result would have been different, as a substance so soluble and nonpoisonous substance would have been formed, which could have been siphoned out of stomach. The case with which this method can be applied, the minimum of trouble and inconvenience and danger recommends itself before the stomach pump, glass tubing or even feeding bottle tubing. Though small, can be quickly procured; then if either a glass or tin funnel cannot be found, one can be made of paper.

A MEDICAL MILLIONAIRE.

It is not often, says the *Deccan Herald*, that anybody in Hyderabad awakes to suddenly find himself in El Dorado, revelling amid piles of silver, nor is it often that anybody meets with a windfall such as Dr. Dyce, the medical attendant to Nawab Fakr-ul-Mulk, has come in for, or rather expects to come in for. We have had the pleasure to witness a genuine document by which Dr. Dyce is entitled to inherit £200,000 in England and Rs. 20,00,000 in India.

LETTERS, COMMUNICATIONS, Etc., have been received from:

(A) Mr. G. J. Auburn, Morpeth; Alpha. (B) Mr. W. Berry, Wigan; Mr. P. O. Bell, Kingston-on-Thames; Mr. C. Bell, New York; D. J. M. Bone, M.B., Hornby; Mr. J. Bird, Basingstoke; Mr. J. W. Brown, Sheffield; Dr. F. Beach, Kingston Hill; Mr. J. M. Bennett, Nottingham; Dr. D. C. Black, Glasgow; Dr. M. A. Bamby, Chappelltown; Dr. J. W. Butterham, St. Leonard's-on-Sea. (C) Mr. H. E. C. The Marvelous Oration, 1894, delivered before the Royal College Physicians, October 18th, 1894. By T. Lauder Brunton, M.D., F.R.S. London: Macmillan and Co. 1894. 2s.
Plea for a Simpler Life. By F. S. Keith, M.D. London: A. and C. Black. 1895. 2s. 6d.
Clinical Lectures on Diseases of the Nervous System. By W. R. Gowers, M.D., F.R.S. London: J. and A. Churchill. 1895.

* In forwarding books the publishers are requested to state the selling prices.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	£0 4 0
Each additional line	0 0 6
A whole column	1 17 6
A page	5 5 0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage stamps.

N.B.—It is against the rules of the Post Office to receive letters at Post Offices addressed either in initials or numbers.

THE INAUGURAL ADDRESS

THE ART OF WRITING IN RELATION TO
MEDICAL AND SCIENTIFIC WORK.*Delivered before the Society of Medical Phonographers.*

BY W. R. GOWERS, M.D., F.R.S.,

President of the Society.

GENTLEMEN, I have the pleasure and the privilege of welcoming you to the first meeting of a Society which is the first of its kind. No systematic effort has before been made to promote the work of a profession by the special means we employ. There means are the immediate reason for our existence, but they are means alone. I would emphasise at the outset the fact that the object of our Society is to promote medical knowledge, to facilitate its acquisition, and especially to augment its application. Beyond this, as beyond all the work of our profession, is the ultimate object—the welfare of others. The fact that the effort to achieve these results can be aided by a special means—the use of shorthand—is the immediate reason for our existence, but it is not our ultimate object.

Why, however, does this reason exist? Why is there a need for our Society, at least sufficient to have induced its formation and to have produced a bright promise of success? Because a hindrance exists to the best and highest work of our profession, a hindrance that is not essential in the nature of things. It is one of the many elements of our life and work that have come to us from the past. The past holds the present firmly in its grasp. With the vast change of modern progress, there is persistence of much that has changed little or not at all. To such persistence we owe indeed the stability of the present; this depends on the permanence of that which is beneath us; that which, upon the surface, remains unaltered amidst the changing elements of progress, often involves a hindrance to action and to work.

Why should a surface hindrance persist and thus retard? That is, indeed, our own question. The answer, however, is suggestive and interesting. However firm is the grasp of the past on the present, it is seldom felt. Wordsworth has told us in a familiar line that

Custom lies upon us with a weight
Heavy as frost.

But the weight of custom, like that of the atmosphere in and under which we live, is all unfelt. "Use and wont,"

old masters of a bygone day,
Many nurses, loving nothing new,

do not allow us to see clearly that which they have charge of. Their personal familiarity from early life, perhaps augmented by influences transmitted through many generations, blunts us to the imperfection of that which is familiar. It likewise dulls the image of that which is novel, and makes it impossible for definite superiority to be duly perceived.

Custom gave us mechanical writing, and stopped all change. Through the centuries since, the sounds of speech have been presented to the eye by symbols that have undergone no essential alteration. They are now, indeed, little less clumsy than when the Phoenicians and Egyptians first gave alphabetical writing to mankind.

Consider our present system of writing as a new invention. Conceive the reception that would be given to it as a nineteenth-century device for presenting to the eye the sounds of speech, for substituting the movements of articulation by movements of the hand. Its defect is only in slight degree a matter of spelling. The reformer of our present "orthography" as it is termed by an inverted metaphor, would have understood the cumbersome symbolism of our present system. It is not only cumbersome, but laborious. About five hundred movements of the hand are required to represent each simple movement of speech, and often this number

is doubled or trebled. Writing can only be easy and simple when the movements of the hand that symbolise each movement of speech and its resulting sound are the fewest compatible with secure and ready perception by the eye. Such simplicity is the basis of phonetic shorthand. It is the facility thus obtained that we desire to extend in the use of the art of writing essential for the work of our profession. Our object is to promote that work by the use of a method of writing that needs at the most only one-third of the time and one-third of the trouble of longhand, and yet has an average legibility more prompt and more secure.

The need for writing in medical work will be self-evident to most, but, perhaps, not to all. Yet its grounds are sufficiently comprehensive. The knowledge has been obtained by observation, and is increased through life by personal observation, and by reasoning based thereon. But in every science that rests on observation, the need for written record is absolute. No memory, whatever its capacity, can be trusted. Immediate record alone can make observation effective. That which is secured by the use of shorthand, even at a low speed, is this: in a given time there can be twice the amount of record that is possible with longhand, and yet twice the time in which to observe. For the greater amount of record observation must be more minute, more precise. Description at once reveals unsuspected uncertainties, and the greater the amount of record the more accurate is the observation, the more valuable is the result. The effect of the use of shorthand is, and must be, on the quality of scientific work so far as observation is concerned. Nor is it alone a matter of quality. Many of the facts observed are changing, passing. In these the effect of the use of shorthand is not merely qualitative; facts can be described which longhand could not possibly record. It must be remembered that shorthand enables, when necessary, not twice, but three and four times the amount of record, and thus transient phenomena can be adequately described which would elude entirely the slow pursuit of longhand, however abbreviated. The difference is thus absolute; observations can be secured that would otherwise be lost. These facts are true of our work as a branch of natural science.¹ I emphasise them because the statements are true of every science which rests on observation, and in all natural sciences the art we advocate would of necessity increase the capacity of every worker, and augment the value of his work. We venture to hope, indeed, that the influence of our Society may ultimately extend the use of shorthand in many other branches of intellectual work and especially in natural science.

But no effect on the quality of work is limited thereto; the worker is influenced as well as the work. If a man habitually observes more fully, more precisely, and more carefully, he must become a better observer, able to perceive more accurately, more minutely, more adequately, and to attain precision more readily. This influence, moreover, whatever its degree must be progressive. We might take as our motto the words "Writing maketh an exact man."

The use of shorthand in science does not stop at the record of observation. It is equally available, with the same saving of time and labour, in the processes of comparison of observations, of epitomising the facts observed by others, and in all the preliminary work of composition. Indeed, I have frequently written the final copy in shorthand; typewriters transcribe it with accuracy, and it is only a question of demand for shorthand MS. to be accurately put up directly in ordinary type.

These remarks have special reference to the work by which medical science is increased and improved. It may be thought that they have little application to the work of the practitioner. Such an idea is a mistake, and, like most mistakes, is instructive by its error. The capacity of shorthand to promote the work of our profession attains its maximum in the aid it can give to the practitioner. Further, the aid it can give the practitioner does not essentially differ from that which it affords to higher scientific work, and the fact is worth noting.

For what is the work of the practitioner of medicine? Of

¹ This Society was started in December, 1891, with sixty members, and has since then increased to 175. Information regarding it and the shorthand system is published in all our publications that are issued can be obtained from the Honorary Secretary, Dr. Neil, Warriston Asylum, Glasgow.

² I have pointed out that shorthand is a better road to the meaning than the language of longhand (Dr. F. J. F. F. F.), formerly head master of the London School of Medicine, and a well-known member of the Society of the shorthand system, has written the following words: "The shorthand system is a better road to the meaning than the language of longhand." (Dr. F. J. F. F. F.)

all those who toil in the busy hives or barren deserts of this earth of ours, he stands in one respect alone. His daily work is to apply science to human need. He avails himself of the knowledge that we have of the processes of Nature without and within the human frame, to strive to avert or arrest disaster to life. He starts equipped with a certain amount of knowledge—as much as he can receive from those who teach him. But he learns more from each day's work. Facts come before him every hour, facts sometimes new, and often new to him. His ability depends on his use of them, on the exactness of his observations, on his adequate retention of their lessons. No practitioner can do his daily work with any competence without constantly observing for himself, constantly reasoning from his observations. The work of the medical practitioner, high or low, is personal science, as that of no other worker is.

Caval as we may at the word "science," no distinction can be drawn between the work of the medical practitioner and that of the highest scientist, save in degree and in the fact that the knowledge is gained chiefly for application. The latter is, indeed, rather a spur than a hindrance. It involves special risks of error, but these are not inevitable. The point to which I would lead you, however, is that for each one of us in our daily work precise record is as necessary as for the advanced investigator. Without the use of writing the facts that pass before him will leave only a transient furrow on the sands of unaided memory, vanishing for the most part when new facts disturb the surface, obliterated by the first of the strong gusts that come and change and go, or at most leaving but a slight modification in mental tendency. Without record there can be no precision; without precision there can be no certainty either of inference or of action. The vague effect of unrecorded—and therefore unconsidered—"experience" is too often a warping of judgment by the influence of some striking but exceptional fact, conspicuous in vague outline in the memory, while the conditions essential to its interpretation are forgotten. Only habitual, immediate record can preserve from these dangers the "personal science" on which depends the work of the practitioner and the welfare of his patients. For this result the record of that which is observed must of course be utilised and so arranged that its value shall not be lost. Yet the mere process of record gives, as we have seen, precision to observation and secures retention, not otherwise to be obtained.

For all this personal use of writing, phonetic shorthand is available with unmixed advantage. Properly written at three times the speed of swift longhand, it can be read as fast as the lips can move, even if written by another person. To teach the mode of employing it to most advantage, and the method of adapting the record to subsequent use, are among the objects of our society, and information on these subjects has already been published by it. I would add, moreover, that the persistent and increasing help to the practitioner's work, obtained through the facility of record that shorthand affords, is a matter of personal experience to which many members of our society can bear the strongest testimony. We have among our members those who have used it with great advantage during forty years, although we cannot produce a rival to Dr. Hall Gladstone, whose use of it in science dates from 1846.

I have said nothing yet of the value of shorthand to the student in gaining the knowledge which the collective wisdom of the profession decries that he shall obtain by the ear. Shorthand enables a student to make a perfect epitome of his lectures, more useful than any textbook, and yet give more attention to the subject than if he took no notes. To attempt to secure a full report of the superfluous verbiage with which almost every lecturer conveys knowledge is a profound mistake. It is an instance of the misuse of the facility in writing which shorthand affords. There is no useful thing, however precious, which may not be misused.

The student's training comprises also the acquisition of knowledge by personal observation—a method of learning which has to continue through life. On his skill in this, much of his future ability depends. Here shorthand is of peculiar value. It renders the help already described, and, in addition to record of facts, he is able to secure the comments on them given by his teachers, which it is scarcely possible to secure at the bedside by longhand. Properly

used, the influence of shorthand on the student's academic career is certain and not small, but far more important is that which it exerts on his future work. He starts on a higher level, with the means of a more rapid rise to thorough practical power.

During the two months long vacation a student can easily acquire a knowledge of shorthand sufficient to make it serviceable and to insure its increase by use. But the object to be desired is that it should be acquired before the medical education is commenced. Many students are now using it to the utmost advantage who learnt it before the commencement of their medical studies. No greater service can be done to any intending student than to secure this acquisition. It is now taught in a large number of public schools, but unfortunately when a knowledge of it is gained it is allowed to drop. Its use is not inculcated, and the lad has forgotten so much of it when he begins his medical career that, without special motive, he does not revive it. The remedy is simple. Shorthand should be an extra, mark-bearing subject in the preliminary examination for the profession. It would displace nothing. Competence in all other subjects would be untouched. The effect on a large number of future members of the profession, on all their work—practical and scientific—would be vast. Some years ago this subject was brought in vain before the General Medical Council, in whose hands the decision lies. But our thanks are due to Sir Dyce Duckworth and Mr. Wheelhouse for their initiation of an effort which must sooner or later be successful.

Although the use of shorthand through life can best begin with the student's work, it has been repeatedly learnt some years after practice was commenced, and its service has been quickly and effectively obtained.

It is a prevalent idea that shorthand can be written but cannot be read. But no writer who has a moderately good knowledge of phonography will fail to confirm my statement that, written at the rate I have mentioned, at three times the average speed of longhand it can be read with far greater security than the longhand, whether the reading is by the writer or by another person. The popular error that it is illegible is due to the immense number of shorthand writers who learn only to write and to immediately transcribe and who have taken no pains to secure the ability to read. Because reading is not a spontaneous result of writing it is assumed to be impossible. The ability to read shorthand can indeed be acquired perfectly without any ability to write it, and is sometimes acquired.

With respect to the time needed for the acquisition of shorthand, this can be much reduced if the learner chooses to give more time each day and does avail himself of the help of lessons. The art of teaching shorthand has been of late years developed to a remarkable degree. An interesting experiment has been lately carried out on some members of our profession by Mr. Hayna, of the Westminster School of Shorthand, which shows that if a man chooses to give to the study two hours a day, with a lesson each day, in a fortnight he will be able to write it at the same speed of longhand, and at the end of a month will have secured its practical use.

Although the swiftest writing ever achieved has been by this system, for our purpose moderate speed and perfect ease are all we need. With three times the speed of longhand, more than three times the ease of writing, and a definitely greater legibility, we may be reasonably content, and it is this we desire to promote in our profession.

If such a combination of speed, ease, and security is at the disposal of anyone who chooses, why do not more avail themselves of the help? Because, like so many other things, it needs a present sacrifice for future good. It needs the power to make that which may be, as potent a motive as that which is. To each man comes, by choice or by necessity, the daily task. The present is actual, the future is only possible, or at most probable. That which depends on the imagination, excited by the assurance of others, is seldom an influence comparable to those motives which are at hand and directly conspicuous to consciousness. Hence it is that so few acquire shorthand, even if they give an abstract assent to the assertion that they and the patients whom they help will be the better for it. They may believe the assurance that the daily hour devoted to the study for a few weeks will be regained within

a year, but there is the present work, ever pressing, and this claims the time and gains it. We talk of the power of the imagination, but bring it in relation to action, and it is seen to be feeble compared with the power of that which is a present reality. What influence on the mind is excited by narrated suffering compared with that produced by witnessed agony? The one is as real as the other, but the intense distress of indignation excited by that which is seen is never equalled by that which is imagined. The difference in motive power is the great hindrance to the acquisition of shorthand as an aid to work that can be done without it, if less adequately. The time that is required to gain the greater power has to be taken from present work; it has to be taken on the assurance of others, and the effect of the assurance fades under the pressure of the present. It may be influential for a week or two, but then the path begins to seem long. The daily time is shortened, then a day passes without study, and soon there comes the realisation of the statement of Whately, that "that which ceases to be habitual, soon becomes habitual in its ceasing." The result is that the attempt is given up, or the knowledge that is acquired is so imperfect as to induce an impression of its capacity, inadequate and erroneous, or a quite mistaken idea of personal inability.

Yet it should not be so. The facts I have dwelt on can be testified by scores of members of our Society, and those who will trust the testimony will not long need such assurance. They will soon have personal experience that will make them altogether independent of the testimony of others.

But it will be asked, Are there no drawbacks to the use of shorthand? One alleged drawback is this: it has been said that the constant practice of making notes weakens the memory, lessens the power of retaining facts without notes.

Without doubt the more the unaided memory is depended on, and cultivated, the greater is its retentive power. But I believe that, as a drawback to the use of shorthand, this impression is an illusion. It is due to the comparison between the extent and precision of the facts secured by record with the small extent and uncertain character of those which are, and alone can be, retained by the memory. The result is a comparison in which the memory seems far more inadequate than it is. The inadequacy of memory is realised as it cannot be by those who trust to it alone, and is ascribed to the use of shorthand. But, if shorthand is properly used, it will involve the retention of a greater amount of knowledge by the memory. If the recorder is not content with a mere mechanical record, but notes mentally while he records; and especially if he, as he should do at the end of his day's work, reviews the record, and considers the lessons of the facts, it will be found that far more is remembered, and that this is remembered better than would otherwise be possible. But even if the opinion were true that the practice of noting all important facts has an influence on the retentive power of the memory—and I am not at all disposed to grant the truth of the opinion as regards the proper use of shorthand—there can be no question of advantage of the two habits thus placed in comparison. To permit this to deter from the acquisition and use of shorthand is, in a degree of more than usual accuracy, to be "penny wise and pound foolish."

For all this, shorthand must be properly known. The great pitfall for medical phonographers is the fact that it can be used for personal purposes when inadequately known, and that the user does not discern how great is the difference in degree, even of personal service, which is entailed by imperfect knowledge. This is, of course, only the assertion that no machine can be properly used until it is thoroughly mastered. Unless some initial trouble is given to bring the knowledge of shorthand to definite adequacy, its full value will not be obtained. Moreover, in accordance with a general law, the absence of that which has not been gained will not be realised. The loss of that which has been is keenly felt, the loss of that which might be, however great the real misfortune it entails, is unperceived.

If we can accomplish these objects, in whatever degree we are successful in our efforts we shall in that degree do more good than we can realise, more than we can see or learn. But this is not all. No good can be done, or, for the matter of that, no evil, which has not its own indirect results of the same character. Such an influence as I have spoken of gives increased knowledge, which, as I have said, is above all the

"knowledge that is power." No man can gain more knowledge without obtaining at the same time more power of acquiring other knowledge. The increased opportunity to learn, which the use of shorthand gives us, causes of necessity an increased ability to learn, and the process of increase in ability goes on and on.

Lastly, whatever our Society can achieve is, like all the work of the profession to which we have the honour to belong, for the good of others. Our immediate object, indeed, may be to our own existence and that of those dependent on us. We can claim no immunity from that mysterious blessing which, in the guise of a curse, accompanied our far-off ancestors in one of the changes they passed through, when labour became the price of life. But the work which we do, by which we live, is that by which as far as may be others live. Whatever good we can achieve, who are here banded together for a common object, is for the benefit of those who in their need depend on our profession. Save for the rare occasions when the use of shorthand can secure some precious words of wisdom that would otherwise be lost, its service to men is greatest when it facilitates, increases, makes more effectual the work that is for others. What the work of our profession is I need not tell you. But this I may tell you, that whatever is the degree of the special help we give to the work of our profession, that help will not be transient, will not be narrow, will not be doubtful. It will endure as long as the science and the art of medicine; it will be wide as the disease we combat; it will be certain as the death we endeavour to postpone.

OPENING OF THE MEDICAL SCHOOLS:

INTRODUCTORY ADDRESSES.

ST. GEORGE'S HOSPITAL.

THE HISTORY OF ST. GEORGE'S HOSPITAL, WITH SOME REMARKS ON IDIOSYNCRASIES.

By G. D. POLLOCK, F.R.C.S.,

Consulting Surgeon to the Hospital.

AFTER a few introductory observations Mr. Pollock said:

It may interest you to learn something of the early life of our school and of the arrangements formerly provided for the teaching of anatomy and other subjects. I need not dwell long on the past history of our hospital. Those interested in the question may refer to an account drawn up in 1866 by Dr. Page, then one of our physicians. The hospital was originally Lanesborough House, the private residence of the nobleman who held that title. It was purchased by the governors of the hospital, and opened for the reception of patients in 1733. But it was found ill adapted for the wants of such an institution: patients suffering from disease and accidents increased so greatly in number that the accommodation was soon found to be insufficient, and it was at last decided by the governors to rebuild the hospital, and this was effected in 1833-34.

But, at that more recent period, the requirements of a thoroughly efficient and convenient hospital, perfect in all sanitary arrangements, were but little understood. The defects of the building, as originally constructed, have been a source of constant and yearly expense in the endeavours to meet the demands of sanitary efficiency and other necessary arrangements. I need not enter into details, but there are still some marked drawbacks, which I hope hereafter may be remedied by the rebuilding and considerable extension of the hospital in the direction of Hyde Park Place. I am sanguine enough to hope and believe that sooner or later—but the sooner the better—the governors will see the importance, if not the necessity, of carrying out such a scheme, and I am glad of the opportunity of thus patently ventilating the question.

In the rebuilding of the present hospital but little provision was made for the conduct of a medical school. A small lecture room adjoined the original museum. There was not any accommodation for teaching anatomy. The

lectures on anatomy were conducted in a private school in Windmill Street, near Golden Square. Here Hunter and Brodie worked and lectured. The teaching of anatomy was then conducted under many difficulties. The school was dependent for the supply of subjects on men known as "body snatchers." Graves of the recent dead would be opened at night, the body removed and conveyed in a sack to the dissecting room; not rarely a body would be taken to the school under suspicious circumstances; and it was this temptation to supply material for dissecting which led to the execution of Burke and Hare for the murder of a man in Edinburgh. Since then the Anatomy Act was passed, which provides that unclaimed bodies may be used for purposes of dissection, in duly licensed schools, under the supervision of the Inspector of Anatomy.

When I entered here as student—1837—there were two anatomical schools, with lectures on certain subjects, not connected with the building. The lectures on Chemistry were delivered at the Royal Institution in Albemarle Street by Brande and Faraday; and many a cold and wet walk have I had to get there at nine in the morning in winter. One anatomical school was in a narrow roadway which ran past the south side of the hospital to Tattersall's Yard, which then occupied a large space of ground in our rear upon part of which this theatre, with the museum and dissecting-room now stand. This alteration was the result of the removal of Tattersall's stables, and for which we have to thank his Grace the Duke of Westminster, one of our vice-presidents and liberal supporters.

The other dissecting-room was in Kinnerton Street, at the back of Wilton Place, and there the lectures on Anatomy, Physiology, and Chemistry were conducted. For several years I lectured there on Anatomy, often hurried to be in time, after a long attendance in the out-patient room.

Not only in this respect are the arrangements for your instruction and comfort materially improved, you have now far greater facilities for clinical work and study, clinical work being, after all is done and ended, the most important subject to devote your time. You cannot give too much attention to the aspects of disease, or disorders, by the bedside with notebook in hand, or if fatal under treatment to follow the case to the *post-mortem* room, and record there the havoc wrought by disease. Here you will find help and instruction from our curator. The study of disease by the bedside, and the investigation of its results when fatal, will lead you to high results, only to be attained by persevering labour amidst many difficulties and oft-repeated discouragements, by labour that chooses its localities as well as its object, and refuses to produce its fruits unless it be pursued amidst the sufferings and sorrows and dangers attendant on sickness and death; by labour that sometimes seems hardly to have begun, until we are called upon to follow it in the dead house, amidst the perishing relics of our fellow men. But see how morbid anatomy, itself a modern science, enables us to look back, as it were, through an avenue upon the countless paths through which death has made its approach; see how we can track him in his progress, and mark how step by step he has gained his territory, and at last has achieved his final victory. But each such victory, if only rightly used, weakens him, while it strengthens us. We learn his wiles, and, increasing our defence, may hope to keep him from life's citadel, until at last those three score years and ten be passed, beyond which life is too often only a prolonged sorrow, whilst death, it is our glorious privilege to know, is the opening of that bright world where disease and pain are known no more.

Formerly two house-surgeons were appointed for twelve months annually, and two house-physicians under similar conditions. Lately the Governors have provided accommodation for four house-physicians and four house-surgeons to reside in the hospital at one time. They are appointed on the recommendation of the Medical School Committee, with this proviso, that at the termination of six months each house-surgeon is transferred to the office of house-physician for another similar period, so that each has the advantage of six months' surgical and medical practice. This arrangement is a most important benefit to those who can take advantage of these appointments, especially so to those who enter the public services, as they carry with them a good knowledge of their profession with much practical experience not often

obtained by many who enter the medical services of the army and navy. It also ensures to those who hereafter may practise surgery alone good practical experience in medicine. I say it with all due respect to our medical staff that a surgeon is, or should be, a physician, and something more.

Let me advise you to devote yourselves chiefly during the first winter session to the study of anatomy and physiology. Steadily occupy your time in the dissecting room, and with the assistance of the demonstrations you should almost master your anatomy to such an extent the first winter as to render dissection almost unnecessary subsequently, at any rate with some work on anatomy, with good illustrations such as may be found in *Quain's*, you should be able to perfect your knowledge of the human body without difficulty. But work, constant, steady work, is essential to the attainment of this thorough knowledge of the anatomy of man.

The study of the structures of the human body when compared with the varieties of similar tissues in comparative anatomy is of such interest that it justifies me in commending it to you for your consideration as one of great interest and intellectual pleasure.

I have congratulated you on your choice of St. George's as the field for all your exertions, mental and physical, to perfect your professional education. You come to the school where Baillie worked, and where he found the material for his accurate illustrations and well-known work on *Morbid Anatomy*, and which rendered his name famous as a pathologist. He had not the advantages of modern years in carrying out his investigations, but nevertheless his work is one which for correct observation and accuracy of detail could not well be surpassed; you may all refer to it with interest and benefit.

John Hunter, too, was surgeon here. It would be presumptuous on my part to say much in his praise. His works tell of his wondrous industry, accuracy, and insight into all that pertains to surgery and its kindred subjects. The Museum of the College of Surgeons contains the results of most of his work in natural history and pathology, and is a lasting monument to his fame. "The range of Hunter's work," says Paget in his Hunterian oration, "matched with its quantity and the time devoted to it; never before or since—I think I am safe in saying this—never before or since has any man been at one time a thorough student and investigator in so wide a field of science. He was an enthusiastic naturalist; as a comparative anatomist and physiologist he was quite unrivalled; among pathologists of his time he was by far the first; among the few geologists and students of vegetable physiology he was one, if not chief; and he was a great practical surgeon, surgeon to a large hospital, and holding for some years the largest practice in this town. In all these subjects at one time no one but Hunter has ever been eminent and active."¹

What Hunter did here is surely a noble example to you all. Endeavour to your utmost to be guided by his work, and endeavour, however distantly, to follow in his footsteps, if your ambition be success in your profession.

'Tis not in mortals to command success;
But we'll do more, Sempronius, we'll deserve it.

I had the privilege and good fortune to commence work here when Sir Benjamin Brodie was surgeon to the hospital. I may truly say that a more industrious, thorough in all work, painstaking and accurate in detail, or a more truthful man could not be met with. He was most particular in the notes taken of his cases; and nothing pleased him more than to find a student at the bedside of a patient with notebook in hand, recording the particulars of a case. If you will investigate the contents of our museum you will find in it much that relates to his work in surgery and pathology. Great industry, great intelligence, great good common sense, and perfect truthfulness were the leading characteristics of his life, and the secret of his success as one of the most eminent surgeons of his time.

Lastly, of those gone from us and surgeons here, I should not do justice to St. George's or to my own feelings, were I not to speak of Caesar Hawkins. His work here did honour to him, and to us. Honest, industrious, truthful, accurate in his observations, and in his teaching he was one of the most clear-minded and well-informed in his profession that it has

¹ Paget, Hunterian Oration, 1877.

been my good fortune to know. It was my privilege to attend him in his last illness. On communicating his death to Sir James Paget, who had known him long, not only in practice but also as a member of the Council and President of the Royal College of Surgeons, I received the following reply, which I feel sure all will be pleased to listen to: "We have lost, I think, the clearest mind in our profession, the mind in which accuracy was least swayed by imagination, or temper, or desire for renown, and I have never known one more completely honest, or discreet in council, or less influenced by self than Caesar Hawkins was. We who knew him well may think ourselves, in this at least, more fortunate than our juniors." Nothing could be more true or more just than these observations. Especially would I draw your attention to the remark made as to Caesar Hawkins being free from all self-interest when consulted during his long professional life. Remember that this is a very great quality, not a very general one. It has been well said: "When self the wavering balance shakes, it's rarely right adjusted." Take the example of Caesar Hawkins, and put selves out of court when called into council, or to deal with questions of conduct, or when your advice is sought.

I was much struck by an observation of Mr. Balfour's, made not long since at a meeting of scientific men, which bears strongly in support of what has just been referred to: "Truth, not profit," he remarked, "must necessarily be the motto of every body of scientific men who desire to be remembered by posterity in their disquisitions."

Gentlemen, your work must be stimulated by honest purposes and rightly-directed ambition—ambition for success and a good name—ambition to succeed, if not to excel, in whatever department of your profession your future may be cast.

Hundreds before me vain ambition cry,

Thousands behind me common sense reply.

Let your ambition be tempered with common sense—rather a rare quality—backed by industry and supported by honest and right-minded conduct; and it is few, indeed, who need fail to gain that success, which such conduct, in most instances, will not fail to secure. But bear in mind still more strongly that it is only too true—"Ambition is a lottery in which there are many prizes, but in dissipation every man draws a blank."

Now in the practice of your profession there are many circumstances which help towards success. One not to be neglected is your personal conduct in your intercourse with your patients. Some men possess the happy gift to impress favourably all with whom they come in contact. All do not inherit this valuable quality, but all may endeavour to acquire some portion of it. There can be no doubt that courteous and refined manners have as much influence in practice as great talent; especially is that success secure when they are combined. Bear yourselves with consideration and kindness towards all with whom you have to deal. Ever remember that in sickness or weakness from disease a patient will appreciate sympathetic attention much more than one in health. A story once told me is, perhaps, as good an example of the benefits derived from amenity of manner as I can relate. A grand uncle of mine, who had amassed a large fortune, was asked by my father what was the great secret of his success in life. He was a charming old man, of most benevolent and lovable disposition. His reply was very simple, but much to the purpose: "I have always found honey catch more flies than vinegar"—a hint that applies to your intercourse with patients equally to that of its adoption in any other call of life. The *suaviter in modo* is a motto ever to be remembered at the bedside of the sick, and should always influence your conduct towards the invalid.

Gentlemen, in the practice of your profession you will meet with a great variety of tempers, constitutions, and idiosyncrasies, which will require all your care, much judgment, and not infrequently much caution to deal with. Of temper and constitution you will judge best how to manage by careful and judicious observation as cases present themselves to you. But of idiosyncrasies I must say something more. The eccentricities of idiosyncrasies in a large number of individuals would require more attention to-day than time will

allow. I must, however, bring to your notice some few instances, that you may fully appreciate the importance, nay the necessity, of treating all such as come under notice with respect, not ridicule.

The following instance is remarkable, related to me by the late Dr. Roupell. A relative of his could not partake of rice without most alarming symptoms. You would say with truth one of the most innocent productions of the vegetable kingdom, one upon which thousands of the natives of India and China almost entirely subsist. Some friends of the person referred to wished to test the truth of this peculiar or supposed effect of rice, and knowing that he was fond of biscuits had some prepared with one grain of rice in each. These biscuits were placed near him after dinner, and he partook of two or three. He became uncomfortable, and had to leave the table, observing at the same time that if he were not morally certain he had not partaken of rice at dinner, he was being poisoned by it.

Another amusing instance is that of a man who could not eat gooseberries without their producing an eczematous eruption on some part of the body. When dining with a fashionable party, soon after the champagne had been handed round, he observed to a friend sitting next to him—and from whom I heard the facts—that the wine was not champagne, but gooseberry wine, and pulling up his shirt-sleeve, showed him the specific eczematous rash appearing. But what applies to the rice in the one case, or to the gooseberry in the other, also applies to many drugs in our Pharmacopoeia.

Be careful in prescribing whenever your patient may tell you that a certain drug does not agree with him. Sir Russell Reynolds has sent me the following notes: "An elderly lady and patient known to me was highly susceptible to the influence of opium in any form, even to the minutest dose, its use inducing symptoms like Asiatic cholera. Many years before I had witnessed these effects she had casually mentioned this peculiarity to me. In prescribing for her when suffering from bronchial catarrh I put in 10 minims of compound tincture of camphor. About half an hour after I was summoned, and found that she had been vomiting and purging, and was in a state of collapse. I had entirely forgotten the peculiarity with relation to opium, and in prescribing scarcely realised that in ordinary paretic I was prescribing opium. In this case the dose of opium must have been $\frac{1}{16}$ th of a grain." Mercury will salivate rapidly in some instances, whether given internally or applied in the form of ointment. The importance of this fact in practice is illustrated by a case which occurred to me when surgeon here. I had operated on a young woman for cleft palate. The parts were satisfactorily brought together with every prospect of early and complete union. In almost all operations in the mouth the tongue often becomes much coated. The house-surgeon of the day considered it desirable to order a dose of calomel in consequence of the state of the tongue the day following the operation. The patient became most freely salivated, with the result that all union of the wound was arrested, and for the time being the operation proved abortive. I could refer to other instances of idiosyncrasies with respect to the influence of opium, belladonna, and other drugs, but I think I have said sufficient to convince you of the importance of treating all idiosyncrasies with careful consideration. No doubt several of you can recall instances of idiosyncrasies in your intercourse with relations and friends, but what I wish to impress upon you is the importance of not ignoring, in practice, cases you may have brought before you. Treat them with respect, not with incredulity or contempt.

Lord Byron in his reported conversations with the Countess of Blessington remarked to her that "medical men do not sufficiently attend to idiosyncrasies on which so much depends, and often hurry to the grave one patient by a treatment that has succeeded in another. The moment they ascertain a disease to be the same as one they have known, they conclude the same remedies that cured the first must remove those of the second, not making allowance for the peculiarities of temperament, habits, and disposition, which last has a great influence in maladies." These remarks are simply exaggerations of feeling and fact. Byron was not one enamoured with the medical profession more than he was with professors of divinity, but he was an acute observer, and

It was interesting to me to read his views respecting idiosyncrasies. He judged rightly—very rightly—of their importance in connection with the practice of medicine.

Observe, gentlemen, that he makes use of the word "cure" to denote "treatment," a word too frequently used without reflection by the world generally, and quite inapplicable to the circumstances of our successful attendance on the sick. The empiric proclaims that the administration of certain drugs, or a combination of them, is essentially a "cure" of such and such a complaint, but the rightly thinking and experienced medical man will tell you to bear in mind that "cure" is not a term to be used by the educated practitioner. What can or do we "cure" in disorders or disease? Nothing I fear. We treat and watch with care "all the ills that flesh is heir to."

By judicious treatment we may sometimes shorten an attack of illness, and probably do so in many cases of sickness; but the mysteries and course of disease are influenced much more by causes over many of which we have absolutely no control. Take for instance the eruptive diseases of childhood or mature life. Do we by treatment cut short the progress of scarlet or typhoid fever, or other disorders which need not be enumerated? The late Dr. Wilson, physician to this hospital, a great scholar and a man of great observation and reflection, was ever strongly opposed to the use of the word. It was he who first impressed me with the importance of discarding it as incorrect in all our views with respect to the action of medicines. Patients, he would observe, may "recover" under treatment, but we do not "cure" them. "Some credit must be given to Nature for her assistance in the recovery." "Cure" is the motto of the empiric.

There is another point of practical importance, gentlemen, to which I particularly wish to direct your attention. You will have to listen to many a tale, or history of a case, from a patient, or one who in practice may require your co-operation. Listen to all that may be told you with attention and consideration; but whatever he told you, be sure to satisfy yourselves that you have facts and not mere statements to guide your decision, and upon which you have to form your diagnosis and decide your treatment. Take nothing for granted. Take every precaution to establish in your minds the absolute truth of all related to you, and seek for yourselves the symptoms to establish that truth. I heard it once said, and it has remained engrafted in my mind, "that in medicine, as in most other callings, taking a thing for granted, without satisfactory evidence, was often the cause of more mistakes than ignorance."

UNIVERSITY COLLEGE, LIVERPOOL. THE EXAMINATION SYSTEM.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S.

Emeritus Professor of Surgery in the London Hospital Medical School.

MY LORD DUBBY, LADIES AND GENTLEMEN.—In searching round for some topic which should prove of general interest on the present occasion, I have hit upon that of Examinations. It is one which concerns us all. We have all of us been examined, most of us expect to be examined again, some of us are examiners now and others will be in the future, and finally a few of us are ex-examiners looking back upon our own careers, and reflecting with much interest upon the whole machinery of modern education, of which examinations form such a prominent part. I am thinking not solely of our professional education, but am venturing for the moment to glance over a wider field. Examinations are the order of the day, and, without much regard of sex or station in life, we now see the youth of the whole community offer itself as so much subject-matter for the examiner's scrutiny. The motives for this vary in different cases. With many it is the necessity of obtaining a certificate or diploma essential to success in life, with others merely a desire to be honourably distinguished, and with yet others a conformity with custom and an unwillingness to be in any sense left behind.

Various, however, as may have been the motives which have drawn students to the Examination Room, of one point there will have been uniformity, and it is most important. It is this, that the scope of the examination in prospect has

been of all importance in determining that of the previous course of study. "This I shall want;" "That I shall not be asked," has been the ever present thought in the selection of subjects for reading and thought. Whatever was deemed not likely to be asked for has been ruthlessly put aside, whatever its intrinsic interest. The demands of the examiner set the pace of study, and the breadth of the examination determines the narrowness, or otherwise, of the student's education. Such being the facts, and the probability being that they will increase in cogency as years go on, it is obviously of the utmost importance to the community that careful consideration should be given to the perfecting of our examination system. It may be a hindrance to the spread of knowledge and the development of the mental powers, or it may if carefully managed become a powerful aid to both.

The aim of sound education should be to convey to the coming generation as much as possible of the knowledge already acquired by its predecessors, and in doing this to still leave the faculties untrammelled and the memory not overburdened. The teacher, whilst seeking to create and to satisfy the appetite for knowledge, must above all things be on his guard lest his well-intentioned endeavours may repress it and cause disgust. I fear it is not very likely that pluck examinations can ever be made to do much to foster the love of knowledge. Here and there it may by chance happen that a mind is led to see the attractiveness of some subject which would have escaped his attention had it not been thus forced upon him, just as a sportsman may see the beauty of a wild which he would never have visited but in pursuit of game. In the main, however, it is all the other way, and the fog of preparation and the innate dislike of giving reasons on compulsion create distaste rather than otherwise for the subjects concerned. Against this—it is to be feared the natural result of compulsory examinations—it is wise to take all possible precautions. Examinations should be made as little distasteful as possible.

To this end it is essential, in the first place, that the element of uncertainty should as far as possible be eliminated. The candidate ought to feel throughout his studies that in presenting himself to an examiner he does that which is equivalent to placing himself in a weighing machine, and that the verdict recorded will be in exact relation to his deserts. In proportion as the hope is indulged that success may be attained by good luck will the thoroughness of study be neglected, and just as it may be possible to suspect that the mood of the examiner, the complexity of a question, or some other accidental circumstance may have influenced the result, will be the disappointment and vexation of a pluck.

These considerations bring us at once face to face with details. It has been, I believe, the steady tendency of all Examination Boards to dispense with personal contact between the examiner and the examined, to trust more and more to written questions and answers. To take as instance our own College of Surgeons, the time is not so very long ago when Sir Astley Cooper and a few of his colleagues met together after dinner and in a very short space of time and with very little formality indeed decided the fates of a batch of candidates. If a student were a man of gentlemanly bearing, if he had studied at the proper school, and did not display gross ignorance, he was in no sort of danger. The examiner might ask his name and place of birth, and possibly send a kind message to his father or uncle. All this has been changed now, and so much for the better, that a feeling akin to reluctance arises in asking you to entertain the question as to whether further improvements are possible. A large part of the examination is now in writing; it is divided into various departments, and occupies probably as many quarters of an hour as the old one did minutes. To be personally known to an examiner is possibly now a disadvantage rather than otherwise, and the responsibility for the result is now shared by a dozen or more of conscientious men acting to a large extent in independence of each other, but never singly. Yet, in spite of these improvements, we still hear complaints—sometimes loud ones, and coming from those who have a right to make them—that the scales of the College do not always weigh correctly. A man may be rejected who was the pride of his teachers, and one may be passed whom they much mistrusted.

That I may avoid the ungracious position of appearing as

the critic of a special institution, and at the same time that I may escape the necessity for repetition I will now venture some general suggestions applicable to all examinations. The personal element, that of the examiner, should be eliminated as far as possible. To this end *vide* examinations should as far as practicable be avoided. I have heard a self-confident examiner allege that he could tell better what was in a man by five minutes' conversation than by reading any number of his written papers, and I did not doubt that he thought so. This judgment of men as it were by personal inspection is often most fallacious, and should be permitted only with the utmost circumspection. Most certainly the impression so formed by any single examiner, or any two associated examiners, ought never to be permitted to override that of their colleagues. In other words, the result of the examination ought always to be determined by the sum of the marks gained, and no rejection should take place in consequence solely of the adverse vote of a single table. This applies to all departments of the examination, but with special emphasis to the *vidé* voce, in which no individual examiner ought to possess the power of rejection. A candidate may be at great disadvantage in *vidé* voce, especially in the hands of an examiner who thinks it his duty to put him to some subject in which he appears weak. The dawning perception of the possibility of rejection may deprive a good man of his resources, and ensure for him a wholly undeserved fate.

Another great objection to *vidé* voce examination is that the decision must be recorded hurriedly, on the spur of the moment, and that there remain no data in evidence to which to recur. Few indeed are the subjects in which a candidate is not most likely to do himself justice (whether to his advantage or otherwise) in a quiet half-hour with pens and ink.

It by no means follows that the disuse of *vidé* voce would throw us back wholly on set verbal questions. There remains the extensive field of objective examination. Under this head we have the identification of specimens and the use of the microscope and of chemical tests, and the diagnosis of disease in the living patient. This kind of examination it is which conduces most of all to sound matter-of-fact objective teaching. It is perhaps the most important of all modes, and is one which in the future is destined to receive more and more attention. Although it may be admitted that the diagnosis of disease in patients can never be suitably done excepting in the presence and under the supervision of an examiner, yet it is better that the latter should not interfere by question or suggestion, and that the candidate should be permitted at his leisure to write out the opinion which he has formed.

We come next to the consideration of papers and of paper setting. Here I have an innovation to suggest. It is that examiners should not be allowed to extemporise their questions, but should be furnished with lists of approved ones out of which to select. It is impossible to deny that of these now set, many are ill expressed and some wholly unsuitable. It is no legitimate part of an examination to take the candidate by surprise, or confound him with the unexpected. Nor should half of the time allowed be taken up in the effort to understand what the terms of the question are intended to mean. Yet obscurities of this kind are inevitable under the present scheme of question setting, which involves the preparation of them by men under much pressure of other engagements, and with but little time at their disposal. Questions suitable for examination purposes should be devised at leisure, and expressed in the clearest possible language.

Under this plan each separate examination should have its own catechism of questions to which the examiner should be restricted. Of this a revised edition should be published every five years. It should be a rule that a third of the questions selected should be of the objective kind, and should necessitate the recognition or description of something. By this precaution the evils of cramming might be forestalled, for the crammer must perforce become the teacher of sound knowledge.

One great collateral advantage of systematic and exclusively of written examinations of the kind suggested, would be that those conducted by different bodies might be brought

more nearly into uniformity. The written answers should be preserved, and in the case of our own profession ought to be producible at any time on the demand of the General Medical Council. Nor would there be the necessity which is now supposed to exist for the employment of seniors in the profession as examiners. Younger men having leisure, and working under the supervision of an experienced chief, might do the work not only as well but much better. It must be noted as a distinct drawback in our present system that those employed in it are men whose time and thoughts are very fully engaged in other matters, and who came to their examination work already wearied with that of the day. A never failing answer to all projects of reform is that the time of the examiners must be considered, and proposals which would involve either extension of time or addition of work are sure to encounter determined opposition. The machinery of examinations will, however, never work satisfactorily until considerations of time and trouble are put wholly aside. Nothing is more essential to just conclusions than that the process should be conducted with leisurely quiet; nor, let me add, should it be in the hands of those who, in consequence of frequent changes and short periods of office, are more or less inexperienced. It is the fashion to hold that anyone who knows his subject can examine in it, but in truth it is not so, and the art of examining is one which, like other arts, needs to be learned. The man who has been some years at work makes, I feel sure, other things being equal, a far more trustworthy examiner than a novice. To some extent, especially in some departments, examining should be a profession in itself.

I am aware that there are differences amongst those well-entitled to their opinions as to the advantages of subdivision in examinations. It is sometimes sought to throw mild ridicule on divided examinations by speaking of them as "taking your dose in teaspoonsful." It is thought that by allowing a man to come up in one subject at a time you encourage cramming and voluntary forgetting. I may confess that my own impressions are very strongly in favour of subdivision. In their favour it may, I think, be, in the first place, urged that a much more detailed and practical knowledge may be suitably exacted at a special examination than would be demanded at one which included a great variety of topics. If, for instance, a candidate were allowed to present himself whenever he liked for his examination in ophthalmic medicine and surgery, and to take that subject by itself, he would certainly get it up in a very different fashion from what would probably be the case if he were only going to encounter the risk of a stray question or two as part of an examination in general surgery. He would, in all probability, have attended as an eager and attentive learner at some special institution. Are we to believe that he would forget what he so learnt sooner than he does the scraps of book information with which but too often he is obliged to be content under our present system. He would know well that at such a special examination a much higher standard would be demanded. Having obtained his certificate for eye disease he would proceed with cheerfulness and with a less-burdened mind to other subjects. Undoubtedly much will be forgotten. That is inevitable under every plan. It is not, however, so much the mere change of the attention from one topic to another which tends to obliterate knowledge as the fact that the thing had never been really learned at all. We all remember Dr. Johnson's retort to the man who pleaded that he had "forgotten his Greek."

In support of the principle of divided examinations, it may also be urged that it would permit of the restoration of certain subjects, such as botany and zoology, which have been for well known reasons left aside, and even of the insertion of others. I am here possibly on delicate ground. Permit me to say, however, that I do most certainly hold that a medical man ought to be a well educated gentleman, and that he ought not to wholly omit from his training at any rate an elementary knowledge of those branches of natural science which are organic with his special training. It is quite true that it is no longer necessary to have a sound botany in order to grow the drugs; but there are other and yet more organic motives for its pursuit. As a branch of the great science of biology it presents us with lessons which are full of interest and instruction. The same is to be asserted

of zoology, and with perhaps only little less cogency of geology, climatology, and some other topics. The attainment of knowledge in all these is not difficult, if it be sought in the right way. To that end divided examinations—not perhaps compulsory, but resulting in certificates which should be contributory—would be of great assistance.

The advocates of inclusive or comprehensive final examinations—and amongst these are, I believe, some of our leading authorities on education—urge with plausibility that they are better tests of a man's memory and mental powers. To some extent this may be admitted, but their superiority in this respect is probably very limited. By no means can it be alleged that those whose memories have sufficed to carry them through an examination in half-a-dozen different subjects on one and the same occasion will subsequently retain the knowledge which they then displayed. The diploma or certificate is, unfortunately, no talisman which will secure us against the treacherous influence of the world's pursuits in obliterating the record of the labours of our student days. Some confession of weakness on the part of the present system is, I think, to be found in the limitations which it has been found needful to impose upon the scope of these many-subject examinations. Students are informed beforehand that only such and such topics will be taken. This is, perhaps, not done so much in our medical examinations as in those of general education. Thus, in botany a candidate at South Kensington is informed that fourteen natural orders only will be questioned in, and that he need not know anything of Papaveraceæ, for example, and a host of others. At Cambridge he must add Papaveraceæ to his repertory, but may still leave aside almost all the rest. At most of our examinations the important subkingdom of Fungi may be left out of consideration altogether. I mention these merely as examples; the same principle will be found to pervade other departments, and the result is a sort of patchwork education, the incompleteness of which is much to be regretted. Our children are taught one reign in English history, for instance, or one short period in that of Greece or Rome and do not obtain, as I think their forefathers did, a general, though it is to be admitted a superficial view, of the whole. Modern education, in its zeal to avoid the charge of being superficial, incurs, as it seems to me, that of being merely fragmentary. It aims at thoroughness, but is obliged at once to admit that it can attain it only in certain subjects which, compared with the sum of human knowledge, are but few and small. Let those of us who advocate wide study, and as a consequence wide examinations, face at once this charge of encouraging a merely superficial acquaintance with things. There is much to be said in its favour. Excepting a very few of us, we are all mere smatterers as regards almost all that we think we know. It is not possible to be otherwise excepting at the cost of being wholly ignorant in many directions, and as regards fitness for the affairs of life, better by far a general acquaintance with all that is around us, though it be not very deep, than slices of profound knowledge placed sandwich-wise between thick layers of utter ignorance. In the medical profession more especially is this alternating method of education to be shunned. We cannot afford to allow attainments in one direction to counterbalance vacuity in another. Hence I think a very strong reason for allowing our students to subdivide their studies and take one at a time, with the understanding that they do that thing for the time, well.

I must now, my Lord and Gentlemen, attempt a brief summary of what I fear has been a very discursive address, and then conclude. If I have given to any the impression that I am in favour of increased stringency or of increased leniency in medical examinations, let me hasten to remove that idea. My plea has been rather that our examinations should become more and more an integral part of our educational system, and that by making them more exact and more definite we should enable them to better assist the labours both of teacher and student. The latter especially should be brought to feel that his examinations, so far from being sources of harass and worry, are really his best friends; in guiding his work and at the same time gauging his attainments. I have advocated frequent examinations, but at the same time have urged that the student should be allowed to take one thing at a time, and thus, as it were, to have the

pleasure of counting the milestones in his journey. With the hope of reducing to a minimum the uncertainties of examinations, I have ventured to suggest some curtailment of the privileges of examiners, more especially that they should no longer be invited to exercise their ingenuity in devising extempore written questions, but should have supplied to them carefully prepared lists of suitable ones, which lists should also be accessible to the candidates.

If on some matters I have ventured upon detail which may be thought better suited for a Board of Examiners than for the present audience, my reply is clear. It is time that the public—in the case of our medical examinations I mean, of course, the professional public—should interest itself in this matter. It is one of the widest possible importance, and for reasons which need not now be mentioned it is one in which only reforms of a certain class should be looked for from within. No one conversant with human nature will expect from those actually holding office reforms which might be thought to reduce the dignity of that office. As to *videlicet* examinations, I have suggested that they should give way to written ones. Surely we are behind the day when we keep up the custom of putting specimens into the hands of nervous students and demanding impromptu recognition, when with less expenditure of the examiner's time a quiet hour with half-a-dozen such preparations might be allowed. Who can doubt as to which would best test the pathological knowledge of the candidate? It is the same with the diagnosis of disease in patients.

Many of you listened not long ago, and I believe in this hall, to an address from one whose name stands, I may say without offence to any, as the foremost representative of surgery in Liverpool during the present generation—my friend Mr. Mitchell Banks. He took for his text “the overcrowding of the profession.” I will not attempt to epitomise an address which was throughout racy with humour and yet solid with sense. With most of what Mr. Banks told you I thoroughly agree. More especially we are entirely at one in his conclusion, which was that the safety of the profession lies not in new legislation of any kind, but in its own examinations. His chief proposal was to increase the stringency of the matriculation, and thus prevent at once the entrance of the illiterate. In what I have said to-day I have taken up the same idea, but have carried it a little further, suggesting that arrangements should be made throughout the whole course of study which should encourage the industrious and choke off the incompetent and idle. The key to the whole situation is in the hands of the examiner. Curricula of study are worthless without his aid, and certificates of study granted without examination are of no avail whatever. If our examinations were developed we might almost wholly dispense with both, and leave the student almost at his free will to choose and to change his places of study. Only make our examinations trustworthy and thorough, and we need no other safeguards.

Amongst those who hear me, I doubt not there are representatives of different interests in this matter. The student has been much accustomed to regard the examiner as his enemy, and looks upon any suggestion which he thinks would make the test more stringent almost as unmitigated hardship. Paterfamilias, who has sons to pass, takes the same side with perhaps added warmth, on account of a keen recognition of the probable increase of cost. Striving practitioners who have neither sons nor nephews are, on the other hand, willing enough that the portals of the profession should be more strictly guarded. To one and all let me earnestly say that we are all in the same boat. The student of to-day will be the practitioner of to-morrow. It is possible that the supposed evils of overcrowding have been exaggerated, and I am sure that none of us would like to restrict, were it possible, the number of students to that of the supposed needs of the public for medical practitioners. We put a higher estimate on the value of medical training than would allow of our desiring any such protection. From men educated in the schools of medicine have sprung naturalists, men of science, explorers, and those foremost in every branch of knowledge. This has been our boast in the past, let us take care that we do nothing to frustrate it in the future. Let us put no artificial impediments in the way of entrance to our ranks. Let us, however, at the same time, by careful attention to the

details of our examinations, make sure of this—that if we are to be overcrowded, it shall be by well-educated gentlemen.

MASON COLLEGE, BIRMINGHAM.

PASTEUR AND HIS WORK: THE DEBT OF MEDICINE TO CHEMISTRY.

By Professor PERCY FRANKLAND, F.R.S.,
Professor of Chemistry in the College.

THE general public, although occasionally interested in striking scientific discoveries, is rarely concerned with the causes which have led up to them; they are attracted, so to speak, by the discovery of America, by the prospect of wealth and other advantages to be gained from the achievement, but they trouble themselves little about the previous labours and speculations of Columbus and his predecessors. It is obvious, however, that in reality the causes leading to discovery are in many respects deserving of more attention than the discovery itself, as it is only by carefully studying these antecedents that we can hope to obtain guidance as to how similar success may be achieved in the future. The causes leading to scientific discovery are probably best ascertained by pursuing the historical method, and by following the career of some individual whose achievements have made themselves felt amongst all sorts and conditions of men.

In order that scientific investigations shall become thus widely known, it is, of course, necessary that their results should bear directly upon matters which are of practical interest and importance to the average man. It is but rarely the case that the results of scientific investigation can be immediately applied to the problems of practical life, and hence some of the ablest and most distinguished men of science have worked in comparative obscurity, their patient labours only bearing practical fruit perhaps many years after they themselves have passed away.

In our own time we have had a most striking example of the opposite phenomenon. For nearly half-a-century there has been before the scientific world an investigator who, whilst certainly not courting publicity, has nevertheless achieved a celebrity which has hardly been approached, and I think assuredly never surpassed, by that of any *savant* in any age. I think it may be said without exaggeration that there is no scientific name which is so universally known, and in so many different connections, as that of the man whose work forms the basis of my discourse to-day.

Chemist, physicist, biologist, and medical man each recognise in Louis Pasteur the author of some of the most important and fruitful departures in their several branches of knowledge; but, more than this, large sections of the industrial and agricultural worlds look up to him with gratitude and veneration for having placed many of their most uncertain and apparently capricious processes on a sound scientific basis, which has tended to largely increase their profits and in some cases to save them from actual ruin.

As M. Pasteur has now passed the age of three score years and ten, he may be said to have joined the ranks of the grand old men of the day, and it is in no way detracting from his prestige to say that his productive life has closed, for, like so many men who have exerted enduring influence on the world, M. Pasteur's fertility is shown in old age not by new labours of his own, but by the ceaseless toil and brilliant achievements of those numerous disciples who owe their success to the inspiration which they have received from the master, and it is this continuous advance of such children in science which is the true philosopher's dearest immortality.

It appeared to me, therefore, that this would form a fitting occasion to review what this great master has himself accomplished, and to trace the influence which his rare and versatile genius has exerted and is still exerting in various directions.

If a novelist were portraying the life of a *savant*, I venture to think that he would in general represent him as passing with increasing years from comparatively simple to more and more abstruse themes, becoming less and less intelligible to the general public, and pursuing investigations of more and more purely scientific and less and less practical bearing. It is, however, of only too

frequent occurrence to find the man of letters going astray when he attempts to enter the world of science, and in respect of Louis Pasteur such portraiture would be fundamentally wrong, for with each succeeding year his work has become less abstract, and has appealed to a wider and wider public, until at length even those who systematically shun science and everything that is connected with it, have been perforce compelled to sullenly receive and heed his teaching. The first researches with which Pasteur made his *début* nearly half-a-century ago, at the age of 25, were of such an abstract character, that had his career terminated with their completion the general world would never have known his name, and yet the initiated few would have been able to recognise one of the shrewdest scientific observers of this or any age.

The strict mathematical as well as chemical training which Pasteur had received as a student at the Sorbonne and at the École Normale, not unnaturally led him to be fascinated with those wonderful geometrical forms which are assumed by solids in what is known as the crystalline state. Now, amidst the marvellous and varied phenomena of crystallisation Pasteur had the remarkable intuition, or perhaps good fortune—for there is luck in the laboratory as well as at cards—to at once select for detailed study almost the only one of these phenomena which even up to the present time has been of much value to scientific progress.

The phenomenon which attracted the attention of young Pasteur was, as all chemists know, the existence of two tartaric acids apparently identical in chemical composition, in chemical properties, in crystalline form, and, in fact, in every detail excepting alone that the solution of one of these tartaric acids had no effect on polarised light, whilst the solution of the other turned the plane of polarisation to the right.

These two all but identical tartaric acids had been examined by some of the most accomplished crystallographers of the day, by Mitscherlich, by Biot, and by M. de la Provostaye, but the younger and keener eyes of Pasteur detected a minute point of difference which had escaped those of these skilled observers. Submitting these crystals to the most searching scrutiny, Pasteur found that there were some minute faces on the crystals of the tartrate which was active to polarised light, which faces were absent from the crystals of the tartrate inactive to the polarised beam, and such importance did he attribute to these little faces, that he recognised that their presence relegated the substance possessing them to an entirely different class of objects from that to which belonged the substance possessing them not.

For whilst the crystals of the inactive tartaric acid, which were destitute of these little surfaces, he found were symmetrical, the crystals of the optically active tartaric acid he found were unsymmetrical or *dissymmetric*, as he called it. Now to the symmetric character of the crystals of the one tartaric acid he attributed the inactivity of this tartaric acid to polarised light, whilst with the dissymmetric character of the crystals of the other tartaric acid he connected its action on the polarised beam.

The intrinsic and fundamental difference between these two classes of bodies—the *symmetric* and the *dissymmetric*—is perhaps most easily realised by placing them before a mirror, when in the case of the symmetric body the image will be identical with the object, whilst in the case of the dissymmetric body the image and object are not identical, but bear the same relationship to each other as the left and right hands do, which are perhaps the most familiar instances of dissymmetric objects. Thus placing the crystal of active tartaric acid in front of a mirror, the reflection obtained is not the same crystal as the original, but related to it as the left hand to the right hand; but on placing the crystal of the inactive tartaric acid before a mirror, the image is in every respect identical with the original crystal.

In studying these apparently insignificant details, Pasteur found that by crystallising the inactive tartaric acid in a particular way he obtained two different kinds of crystals, the one set being identical with those of the active tartaric acid already known, whilst the other set were the mirror images of these, and had never been seen by the eye of man before. The young philosopher at once drew the conclusion that if the dissymmetry of the known tartaric

acid caused it to turn the plane of polarisation to the right, the dissymmetry of this new tartaric acid would turn it to the left.

With infinite pains Pasteur picks out from the mixture the individual crystals belonging to each of the two types, and arranges them in two heaps; each of these heaps of crystals was then separately dissolved in water, and the two solutions submitted to polarised light. In accordance with his anticipation, whilst the solution of the crystals of the known form was found to turn the plane of polarisation to the right, the solution of the new crystals, the mirror images of the old, was found to turn the plane through precisely the same angle to the left. This might have appeared to many a trivial discovery only, but such was not Pasteur's opinion of it, for rushing from the laboratory in a fever of excitement and meeting a fellow assistant in the corridor, he embraces him, and exclaims, overcome with emotion, "Je viens de faire une grande découverte!" And such in truth it was, although almost his first discovery, and the one which has the least contributed to the general celebrity of its author, it is nevertheless almost impossible to overestimate its importance in view of the remarkable fertility of the researches to which it has directly and indirectly given rise.

Although Pasteur pointed out that the differences in optical properties and in crystalline form exhibited by these two oppositely active tartaric acids were doubtless dependent on the two molecules having a different arrangement of their constituent atoms, the arrangement in each case being dissymmetric, and clearly indicated that whatever the dissymmetry of the one tartaric acid might consist in it must be related to the dissymmetry of the other tartaric acid in the same sort of way as the dissymmetry of the left hand is related to the dissymmetry of the right hand; still at the time organic chemistry was not sufficiently advanced to make any immediate use of these speculations. The remarkable progress and development of organic chemistry which characterises the latter half of the present century, before long led to the further interpretation of these phenomena exhibited by the tartaric acids. For some years later (1850) Wislizenus was confronted with similar phenomena in the case of lactic acid, and with the more perfect knowledge which had then been gained as to the grouping of the atoms in the molecule, he was led to hazard the suggestion that the difference between the two lactic acids was due to a difference in the arrangement of the atoms in the molecule which could not be represented by the ordinary plane formulae of chemists, but required a consideration of the arrangement of the atoms in the three dimensions of space.

This suggestion, giving as it did further substance to Pasteur's previously expressed views of dissymmetry, was the foundation of that most fascinating and fertile field of chemical science which is now known as stereochemistry, the guiding principles of which were elaborated in 1874 with such rare skill and prescience by Van't Hoff and Le Bel, and which, like nearly all new and original departures in science, met at the outset with the most withering criticism and even scornful ridicule from some of the conservative and fossil professors of the time.

These views, concerning the spacial arrangement of the atoms within the molecule, have, however, long since passed their probationary stage, and their provisional acceptance at any rate has become absolutely indispensable to a proper understanding of recent advances in our knowledge of the carbon compounds. The fertility of these views in stimulating successful researches has been almost limitless: thus some of the most brilliant achievements of modern chemistry, such as the artificial synthesis by Ladenburg of the alkaloidal poison *Cocaine*, which forms the deadly instrument of execution concealed in the cup of hemlock, and the wonderful series of investigations, which in the able hands of Emil Fischer, has culminated in the preparation of some of the principal natural sugars, these investigations owe their success entirely to the guidance of those theories of stereochemistry, which are the direct outcome of Pasteur's fundamental researches on the tartaric acids.

The theory of the arrangement of the atoms in space has, however, also been applied with great success to substances which have no action on polarised light at all. Amongst the enormous number of organic compounds prepared and accu-

ately studied during the past fifty years it has repeatedly been found necessary to assume that in some the atoms are arranged in a closed chain or ring, as opposed to the open chain arrangement which must be assumed to exist in many others. Now one of the most striking things about these closed chains is the fact that they almost invariably consist of either five or six atoms; a vast number of these ring compounds are in fact derivatives of the well-known hydrocarbon benzene, in which chemists have long recognised the presence of a ring consisting of six atoms of carbon. This remarkable predisposition to form five or six atom rings finds a ready explanation when Van't Hoff's tetrahedral arrangement of the carbon bonds and the relative positions of the atoms in space are taken into consideration.

The fertility of these speculations has led to chemists constructing similar hypotheses with regard to the arrangement in space of the groups attached to nitrogen atoms, the investigation of which is being eagerly prosecuted by numerous workers at the present time, whilst others still more imaginative are extending stereochemical views even to some of the compounds of platinum, cobalt, and other metals.

By these first researches we see, then, that Pasteur became the father of one of the most wonderful departments of modern chemistry, namely, the one which has for its ambition the discovery of the spacial distribution of the individual atoms in the molecule. Thus, Pasteur's first researches possessed in themselves purely theoretical interest; they were, however, masterpieces of thoroughness, and exhibited so much experimental skill, intuition, and power of careful observation combined with clear judgment, that, even had his career been cut short at this stage, we should have had no hesitation in recognising in him one of the most remarkable and exceptionally gifted of investigators. From these early researches, however, we should have had no positive indication of the man's power of harnessing science to the problems of practical life. His genius was, however, not long to be retained in the exclusive service of abstract science, and it is interesting to follow the circumstances which led him to find scope for the practical side of his abilities. It was not, as many might suppose, that he had suddenly set himself some definite problem of great practical moment to work out, for in scientific investigation it almost invariably happens that one step leads to another; the experience gained in one piece of work qualifies the worker to follow on in some definite direction and not to plunge into the unknown at random. Thus, in Pasteur's case the great practical work of his life followed almost as a necessary consequence on his achievements in the purely scientific domain to which I have already referred.

In the course of his experiments on the different kinds of tartaric acid, he was led to try the effect of submitting them to fermentation, for it was already known that ordinary tartaric acid underwent a process of fermentation when left in contact with dirty water.

Submitting this process of fermentation to his penetrating scrutiny, he made the remarkable discovery that whilst ordinary right-handed tartaric acid suffered complete fermentative decomposition, the inactive tartaric acid (known as racemic acid, and which he had shown, as we have seen, to be a mixture in equal parts of left and right-handed tartaric acids), was only partially fermented away, the unfermented residue proving to be left-handed tartaric acid.

In plain language this means that whilst right-handed and left-handed tartaric acids are chemically identical, and are distinguishable only by their crystalline form and opposite action on polarised light, they are, nevertheless, utterly different from a physiological point of view; for the right-handed tartaric acid is alone taken up and transformed by the fermentative bacteria which refuse to have anything to do with the left-handed tartaric acid. Thus the apparently trivial difference in the arrangement of the atoms in space in the case of these two tartaric acids makes an overwhelming difference in their physiological character.

This phenomenon, which is undoubtedly one of the most striking in the whole domain of chemical science, appears to be a very general one in the case of bodies admitting of two or more different arrangements of their atoms in space. Although not further pursued by its discoverer, this subject

ological difference has been largely utilized by subsequent investigators for the preparation of optically active compounds.

The study of these optical properties of the tartaric acids had thus by accident as it were drawn Pasteur from the inanimate world of pure molecular chemistry into the vortex of the world of life, and to the study of vital phenomena practically the whole of his genius and energy was subsequently devoted.

If, as I have endeavoured to show, his influence on molecular chemistry has been of the most profound and far-reaching character, in the domain of biology his influence has been no less remarkable and stimulating. The frontier line, which Pasteur crossed from chemical on to biological soil, was at the time as undefined, and as much a matter of debate, as is the line of demarcation between the spheres of British and Russian influence in Central Asia. For the phenomena of fermentation which Pasteur had attacked were, in fact, not generally regarded as vital phenomena at all. For, when Pasteur crossed what proved to be this Rubicon in his career, the dominant opinion concerning the fermentation processes was that of Liebig, who viewed the classical transformation of sugar into alcohol as a purely chemical process, and depending not upon the living yeast cells which the microscope revealed, but upon the dead yeast undergoing *post-mortem* decomposition. Every foreman in a brewery to-day is better instructed on this subject than was the great Liebig thirty years ago. It will, however, be easily understood that the firm conviction of this brilliant man of science was not to be overthrown in public estimation in a day nor by the mere enunciation of a counter dogma. It required years of patient labour, in which almost every form of fermentation was submitted to careful experiment, before the old ideas which rested upon such high authority as that of Liebig were finally abandoned and made to disappear.

Not only was the fermentation of the grape juice in the production of wine, the fermentation of malt liquor in the brewing of beer, the souring of wine in the manufacture of vinegar, the souring of milk, and other fermentation processes of less general interest shown to be the work of microscopic organisms, but each fermentation process was shown to be the work of distinct organisms, and that the work of one set of organisms may be interfered with by the presence of another set of organisms, as the crop of wheat may be interfered with and choked by the proverbial tares of the enemy.

It was here that the practical value of Pasteur's researches first began to assert itself. The results of his fermentation experiments, embodied in his imperishable *Etudes sur le Dière, sur le Vin, et sur le Vinaigre*, were not merely of high theoretical importance; they did not only appeal to the philosopher, but had to be studied by the man of pounds, shillings, and pence, engaged in producing those commodities which are the result of fermentation processes. Knowledge and appreciation of his laboratory results has meant wealth to the brewer, the distiller, and the wine grower, whilst ignorance of his work and inattention to his teaching has with even greater certainty meant bankruptcy and disaster. It is indeed no exaggeration to say that the modern brewer is able to almost effortlessly endure the relentless taxation of the late Chancellor of the Exchequer as much through the labours of Pasteur and those who have succeeded him as through the unquenchable thirst of the British public.

Exclusive as were Pasteur's researches in the domain of fermentation, there were persons of this nature whose time did not permit him to investigate before he was hurried on to other fields of scientific interest and practical utility. His intellect, however, led him to investigate some of the subsequent controversies in this direction. Thus he indicated as a probable fermentative process—that is, a process dependent on the vitality of microscopical forms of life—that chemical change known as *nitrification*, which consists in the conversion of ammonia into salts of nitric acid, and which takes place upon a gigantic scale in all the fertile soils of the earth. This process, which had always been regarded as a case of direct and simple oxidation, was a matter of years later shown, indeed, to be entirely due to the agency of bacterial life, whilst it required the further steps of time before the methods of bacteriological research were sufficiently advanced to admit of the isolation and study

of the particular micro-organisms responsible for this important nitrification-process, upon which depends not only the fertility of the soil, but also the production of gunpowder, as well as of nearly all the more modern explosives of peace, anarchy, and war.

But almost still more remarkable revelations in connection with agriculture have resulted from the careful study of bacteria during recent years. For it has been shown that, contrary to the general opinion of some of the most careful and competent experimenters of the last generation, certain green plants are apparently able to obtain the nitrogen which they require for their nutrition from the atmosphere, and that this assimilation of free nitrogen only goes on when the soil is infested with certain micro-organisms which provoke the formation of nodular excrescences on the roots, and that, when these micro-organisms are carefully excluded, neither do the root nodules make their appearance, nor is the assimilation of free nitrogen accomplished.

Uncertainty long prevailed as to the respective parts played by the plant and the microbe in this nitrogen assimilation, but the comparatively rough experiments of Berthelot, and the more recent researches of that accomplished bacteriologist Winogradsky, clearly show that this nitrogen assimilation can take place by particular bacteria alone in the absence of any green plant whatever, provided these bacteria are supplied with the necessary quantity of sugar or other carbohydrates, and that the fixation of free nitrogen goes on *pari passu* with the destruction of the carbo-hydrate. These researches of Winogradsky are of the very highest interest, as they clearly show that, with the exception of the few direct syntheses of nitrogen compounds from free nitrogen which can be effected by purely chemical means, we must now recognise in these bacteria the silent, invisible, but mighty transformers of free nitrogen, which in its inertness is found only to argon itself, into those multitudinous nitrogen compounds, the wonderful metamorphoses of which are the foundation of the whole scheme of living Nature on our globe.

Thus the systematic study of fermentation phenomena inaugurated by Pasteur in 1857 has proved wonderfully fertile; in his own hands it led not only to a strict demonstration of the dependence of the chemical changes involved on the vital activity of different forms of microscopic organisms, but he was able also to indicate how those industries which are dependent on such fermentative processes could be materially improved by attention to the principles which his researches had established. Some of his successors in this field have shown how still further refinements may be advantageously introduced into the practice of the fermentation industries, whilst others, again, have proved that some of the most important processes going on in Nature are brought about by the vital activity of these low forms of life. This wonderful concatenation of discoveries, illuminating the impenetrable darkness which had for thousands of years surrounded the mysterious phenomena of fermentation, shows the wisdom and sagacity of the French Academy in awarding to Pasteur the prize for experimental physiology already in the year 1859, and at a time, therefore, when he had but forged the first links of this chain.

The researches of Pasteur with which I have so far dealt have in every case formed the groundwork on which subsequent investigators have been attracted to assist in raising up a vast and imposing edifice, but I have now to briefly refer to a place of work of great importance, which put, so to speak, the last stone on a structure which had been centuries in building, and the foundations of which must have been laid in the very earliest days of civilisation.

No system of philosophy can make any pretensions to completeness without taking into account the problem of the Appearance of life on the earth, and this problem has greatly exercised the minds of men in all times. The history of this subject is of great interest in many ways, chiefly perhaps on account of the proof which it furnishes of the danger of accepting evidence on authority.

Some of the greatest thinkers and observers of past ages have had very definite views on the subject of the generation of life. Aristotle emphatically states that "every dry body begetting moist, and every moist body becoming dry, engenders animals." Virgil is more specific still in asserting

that bees originate within the putrefying carcass of a young bull. "Aspiculant liquefacta boum per viscera toto stridere apes utero, et ruptis effervere costis."

Again, Van Helmont, the great alchemist and physician of two centuries ago, actually gives the recipe for the production by spontaneous generation of the domestic mouse. His formula consists in squeezing some soiled linen into the mouth of a vessel containing some grains of wheat, which arrangement gives rise to the transmutation of the wheat into mice in the course of about twenty-one days. The mice so generated are said to make their appearance in the adult state, both sexes being duly represented.

In the present century the advocates of spontaneous generation had abandoned their ground as regards such tangible forms of life as bees, frogs, and mice, and had restricted their views to those minutest of organisms which the microscope had rendered visible. The intimate contact in which Pasteur had lived with these microscopic forms during his researches on fermentation naturally led him to take a deep interest in this controversy, into which he plunged with the full vigour and resources of his critical mind, although strongly dissuaded by many of his scientific friends, who feared that nothing but loss of time would come of his venture.

Time will not permit me to describe the experiments, as remarkable for their extreme simplicity as for their clinching force, which were carried out by Pasteur to settle once and for all this question of transcendent importance. His conclusions, which have since been accepted by a whole generation of scientific men, are best summarised in the following incisive words of his own.

"No, there is to-day no known circumstance which permits us to affirm that microscopic beings have come into the world without germs, without parents like unto themselves. Those who hold that they do have been the plaything of illusions, of experiments badly made, tainted with errors which they have not known how to perceive, or which they have not known how to avoid. "*La génération spontanée est une chimère.*"

It was only after this decision, obviously, that the exact study of microscopic life could be proceeded with. Not only does the whole modern science of bacteriology hinge upon this conclusion, but it is the basis of numerous industrial processes for the preservation by so-called "sterilisation" of the most varied articles of food and other putrescible materials which were supposed by the advocates of spontaneous generation to be in themselves the *fons et origo* of a teeming world of microscopic life.

In spite of the unanswerable character of Pasteur's researches, the doctrine of spontaneous generation died hard, and it will be within the memory of some here to-day that the last flicker of the candle took place in our own country, where this remarkable chimera was revived by a distinguished London physician, whose views met with no little favour until they were again confuted and finally demolished by the late lamented Professor Tyndall, whose arguments were based on a brilliant series of experiments, from which even the most obdurate of our countrymen could not appeal.

But, it will be asked, how is it that the name of Pasteur is by the general public only associated with the study of diseases and their attempted prevention and cure when during such a large part of his career he has had nothing whatever to do with medicine? The explanation of the phenomena of disease, and still more their prevention and cure, can surely only be attempted by men who have devoted their lives to medical study and practice. Pasteur, on the contrary, has been spending his best years in studying the crystalline forms of obscure chemical compounds, in unravelling the chemical changes taking place in the brewer's vat, in the wine cask, and in the vinegar factory, he has been devoting years to discredit and overthrow the ridiculous doctrine of the spontaneous generation of life—all of them subjects entirely outside the perspective of the medical practitioner or of afflicted humanity in general.

Plato, in one of his paradoxes, says: "If we wish to become thoroughly acquainted with astronomy, we will let the heavenly bodies alone," and history has abundantly demonstrated at any rate the partial correctness of his prediction, for what is modern astronomy but celestial mechanics and celestial chemistry, the principles of which

have been arrived at not through stargazing but by experiments in the laboratory and calculations in the closet. Still more to the point is the remark of Robert Boyle in the seventeenth century: "The man who shall probe to the bottom the nature of ferments and of fermentations will doubtless be much more capable than any other of giving a true explanation of the diverse morbid phenomena, both of fevers as well as of other affections." Or if I may venture to put his meaning into the terser and perhaps more exaggerated language of Plato, he virtually says: "If we wish to become thoroughly acquainted with medicine, we will let diseases alone and pursue the study of fermentations."

Boyle's words, pronounced 200 years ago, are almost prophetic, so exactly have they been fulfilled in the person of M. Pasteur. Not until the long apprenticeship, which I have endeavoured to outline, had been served was it possible for Pasteur to deal with the still more complex phenomena of disease, and into this vortex he was slowly but surely drawn by his fermentation studies, some of the results of which became immediately available for medical purposes.

It is almost needless for me to remind you that what has hitherto been the greatest and most far-reaching application to medicine of Pasteur's researches on fermentations was made in our own country, for there is no room for doubt that since the discovery of the use of chloroform and other anaesthetics no greater boon has been conferred on suffering humanity than the introduction of the principles of asepsis and antisepsis into the practice of surgery.

That this advance owed its origin entirely to the previous discoveries of Pasteur in connection with fermentation we know, from the graceful tribute paid by its great author, Sir Joseph Lister, on the occasion of the Pasteur jubilee meeting in 1892 when, in the presence of the President of the Republic, the great officers of State, and a brilliant gathering of savants of all nationalities, Sir Joseph Lister, as the representative of our Royal Society, rose, and addressing M. Pasteur, pronounced the words as remarkable for their impressive truth as for their beautiful modesty:

"Truly there does not exist in the entire world any individual to whom the medical sciences owe more than they do to you."

"Your researches on fermentation have thrown a powerful beam which has lightened the baleful darkness of surgery and has transformed the treatment of wounds from a matter of uncertain and too often disastrous empiricism into a scientific art of sure beneficence. Thanks to you, surgery has undergone a complete revolution, which has deprived it of its terrors and has extended almost without limit its efficacious power."

Of M. Pasteur's connection with the foundation and development of pathological bacteriology, and of his contributions to our knowledge of infectious diseases, it will be impossible for me to do more than refer in passing. In this part of his career, however, we are again confronted with that marvellous, apparently intuitive, sagacity which has always led him to investigate such problems as are ripe for successful study, and so to build up the scaffolding from which the more inscrutable, though often more generally attractive problems, can afterwards be attacked. Thus in his pathological researches Pasteur has throughout almost exclusively restricted himself to the study of the infectious diseases of animals, knowing full well that just as progress with infectious diseases was impossible until an accurate and extensive study had been made of fermentation phenomena, so there was no hope of penetrating far into the mysteries of human disease until the more accessible maladies of the lower animals had received thorough experimental attention. But although Pasteur's own researches on infectious disease were principally confined to the disorders of the lower animals, the results of these investigations in many cases at once threw the most valuable light on the nature and mode of propagation of the zymotic diseases of mankind, and gave the most important indications for the carrying out of far-reaching hygienic improvements.

It was well said by Dr. Burdon Sanderson in his presidential address at the Nottingham meeting of the British Association, two years ago, that "the history of scientific progress is largely the history of scientific method," and so the extension of the principles of bacteriology established by Pasteur

to the investigation of questions of practical pathology and hygiene was enormously facilitated by certain improvements in the methods of bacteriological study which originated on the other side of the Rhine, and with which the name of Robert Koch will always be associated. By the simplifications and improvements in bacteriological methods effected by Koch and his pupils, a much larger number of workers were at once attracted into this field of study, which from 1880 onwards has developed with a rapidity almost unparalleled in the history of science.

Time prevents me from dwelling upon the innumerable advances made in every department of bacteriology during the past ten or fifteen years, and upon the manner in which it has risen in public estimation. From being ridiculed as the latest ephemeral fad of scientific men, the public are at length beginning to realise that it is indispensable to the proper appreciation of countless phenomena in almost all departments of science and of practical life. Soon after Pasteur had commenced the study of the bacteria of infectious diseases, he was impressed by the fact that often in the course of cultivation in artificial media outside the body the virulence of these bacteria became diminished to such an extent that they ceased to be fatal on inoculation into susceptible animals. This diminution in virulence, moreover, could, he found, be accelerated or retarded by varying the conditions under which the organisms were cultivated. But the most important discovery in this connection was that the animals inoculated with such enfeebled or attenuated cultures were found to have become protected from the disease even when subsequently inoculated with the most virulent cultures of the same organism. This was the starting point of a long series of researches which have formed, so to speak, the crown to M. Pasteur's labours, and the practical utility of his results, appealing as they do, even to the most unscientific and ignorant, has served to spread his fame throughout the peoples of the entire globe; whilst his successors in this line of investigation have branched out into new fields of discovery almost still more remarkable, and giving promise of even still greater benefits to mankind.

The discovery of this artificial attenuation of virus at once enlarged the scope of Pasteur's investigations, which now included not merely the study of infectious diseases and their exciting causes, but embraced also the artificial protection of the individual against their attack. The most varied methods were devised and successfully elaborated for attenuating viruses of different kinds, and when the utility of attenuated viruses had been adequately demonstrated by laboratory experiments, they were employed for giving protection to multitudes of domestic animals from some of the most destructive plagues with which they are affected.

Pasteur next proceeded to grapple with a disease affecting both man and animals; a disease not remarkable for the frequency of its occurrence, but almost without an equal in the terrible nature of its symptoms. This disease, as you all know, was hydrophobia or rabies. From the manner of its communication from animal to animal and from animal to man this must be a parasitic disease although the actual exciting cause has even still escaped detection. In searching for a method of counteracting this terrible malady Pasteur was taking an entirely new departure inasmuch as in his previous work of a similar character he had always first isolated and cultivated the exciting organism. In the present instance, however, he trusted to his great past experience in preparing attenuated viruses to guide him in the production of an attenuated virus of a disease, the exciting cause of which was still shrouded in darkness. In overcoming the difficulties of this problem the genius of Pasteur triumphed, as it had done in surmounting countless obstacles before. The attenuated virus of hydrophobia was successfully prepared and by several different methods.

Fresh difficulties, however, attended its application, for human beings would not be likely to submit to wholesale protective inoculation in anticipation of the highly improbable event of their being bitten by a rabid dog, and the remedy to be of any practical service to man must be available after the bite by the rabid animal has been inflicted. In this respect the treatment for hydrophobia differed from any attempt which had hitherto been made to counteract infectious disease by means of attenuated virus.

This difficulty has also been overcome, excepting in those cases in which the disease has actively taken root before the protective treatment is begun.

Much controversy has raged over this crucial point as to whether protection can really be conferred by inoculation with the attenuated virus after the bite by the rabid animal has taken place, but in the opinion of those best able to judge in this matter, the statistics, which are now of the most extended character, answer this question in the affirmative.

The conviction that such is the case has led not only to the treatment being continued at the Institut Pasteur on an enormous scale, but centres for carrying it on have been founded in almost every civilised country in the world except our own, although numbers of our countrymen annually cross the Channel to take advantage of the treatment, and during the past year the number of Englishmen who went to Paris for this purpose actually exceeded the number from any other State.

The great problem of securing immunity from disease, which thus occupied the later years of Pasteur's activity, has, however, now entered upon an entirely new phase; for whilst Pasteur's methods depended essentially on submitting the individual to be protected to the attack of the disease-producing organism itself, albeit in an attenuated or weakened condition, the new methods of conferring immunity do not involve any contact whatsoever between the individual and the living virus in any shape or form.

As might be expected, this transition was neither accomplished in a single bound, nor by the efforts of a single investigator, and it is not surprising that the prestige of being the predominant partner in this great achievement should have been claimed not only for several different individuals, but that it should have actually become a matter of dispute between the two great rival nationalities of the Continent. Had it been a dispute in which England were concerned, and which unfortunately it is not, we might perhaps have been reminded of the well-known couplet—

Seven Grecian cities vied for Homer dead
Through which the living Homer begged his bread.

It would be unprofitable to enter into the details of this controversy; suffice it to say that the first distinct step in the transition was the discovery that the artificial cultures of pathogenic bacteria can be entirely freed from these bacteria, or sterilised, and yet produce their characteristic poisonous effects on injection into animals. Thus the poison or toxin of the diphtheria bacillus was discovered by Loeffler, who, it will be remembered, also discovered the diphtheria bacillus itself, whilst this toxin was more fully investigated by Roux and Yersin, as well as by Dr. Sidney Martin. By this discovery the toxins of diphtheria and of several other diseases have been rendered as specific poisons, as are laudanum or the extract of nux vomica; for it is now possible to produce some of the characteristic symptoms of these diseases by the administration of these sterile toxins, just as we can produce laudanum poisoning without resorting to the living poppy.

It was further found that animals can be gradually accustomed to these specific toxins, just as human beings can be gradually inured to laudanum or to tobacco, and the question then arose as to how such animals which had undergone this gradual habituation to a particular toxin would behave on being subsequently inoculated with the disease-producing organism itself. On submitting this point to experiment, it was actually found that the animal which had survived a graduated treatment with the bacterial poison was capable of withstanding the subsequent attack of the virulent bacteria themselves.

Here, then, was a novel achievement indeed—immunity secured for an animal without its having had any contact with the disease-producing organism itself. This important step we owe to the labours of Salmon, Roux, Chamberland, and other investigators.

The next step, which is assuredly the most surprising of all, consists in the demonstration that the blood of an animal thus artificially immunised against the toxin of a particular disease contains materials which can be transferred to another animal with the result that this animal also becomes thereby protected from the same malady. This astounding

antitoxic property of the blood serum of an artificially-immunised animal was first discovered by Richet and Héricourt in respect of animals immunised against the staphylococcus aureus—one of the common abscess-producing organisms.

To Behring and Kitesato, on the other hand, is due the credit of having shown, not only that the blood serum of animals artificially immunised against diphtheria and tetanus respectively is capable of protecting from these diseases other animals into which this serum is injected, but that even after these diseases have been actually contracted they may be cured by the subsequent administration of the antitoxic serum, provided the quantity used be sufficient and its injection not postponed until too advanced a stage of the malady has been reached. Finally, to Behring is due the merit of having extended these benefits in connection with diphtheria to man himself. To indicate the importance of this newly-discovered therapeutic agent I would, in order to save time, merely draw your attention to the following figures, which speak most eloquently for themselves:

Diphtheria Death-Rate per 1,000,000 Living.

	1882-1892	1893.
London	300	760
Manchester... ..	200	260
Liverpool... ..	160	150
Birmingham... ..	120	100
Leeds... ..	60	100
Sheffield... ..	101	180
West Ham... ..	380	450
Bristol... ..	160	200
Bradford... ..	60	100
Nottingham... ..	110	70
New I... ..	60	110
Sancti... ..	390	290

These figures are taken from the Annual Report (1893) of the Medical Officer to the London County Council.

The mortality in Germany from diphtheria previous to the introduction of the serum treatment has been recently shown by Kossel to have been 34.7 per cent., whilst since the application of the new treatment it has sunk to 11.1 per cent.

Kossel has also drawn up an interesting table showing the importance of introducing the serum treatment as early as possible after the commencement of the disease. It will readily be understood how this discovery has stimulated experimentalists in all parts of the world, whilst the supply of the therapeutic serum for diphtheria is already a commercial undertaking of some magnitude.

It is worthy of note that in this production of serum again chemical science has come to the aid of medicine. It is obvious that the preparation of such serum on any scale must involve the employment of a large staff of highly skilled and scientifically trained persons who are not to be collected into any ordinary manufacturing establishment at a moment's notice. Those great industrial organisations, which are principally to be found in Germany, and in the works of which coal tar is converted into all the colours of the rainbow, into the perfumes of Arabia, and into many of the most valued drugs of the modern physician, some of these coal-tar colour manufacturers, with their numerous staff of scientific advisers, have seen their way to still further enlarge their works by adding to them vast stables, in which numbers of superannuated horses are passing a comfortable and useful old age in furnishing the antitoxic serum which is to alleviate the sufferings of thousands of young victims to diphtheria.

But the possibilities of securing protection by means of the serum of immunised animals extend even beyond the boundaries of infective disease. If the serum of an animal rendered insusceptible to a particular disease can counteract the poisons manufactured by the specific bacteria of that disease, may it not also be possible to counteract in the same way poisons that have a non-bacterial origin altogether? Now, it is this that has recently been done in respect of snake poison by M. Calmette in France and by Professor Fraser in Edinburgh. Proceeding on exactly the same lines, these investigators have found it possible to gradually accustom animals to larger and larger doses of the venom,

and the blood serum of such animals is then discovered to be endowed with the power of rendering similarly resistant other animals into which it is injected. When we remember that 20,000 of our Indian subjects perish annually from snake bites, and that the new method of treatment extends the prospect of saving many if not all of these, it is obvious that we are here again face to face with a subject of stupendous importance, and which affects us above all the other nations of Europe.

The brief sketch which I have endeavoured to present firstly of Pasteur's work, and secondly of the further developments to which it has given rise in the hands of others will, I hope, convey some faint idea of how enormous has been his influence on the progress of science during the latter half of the present century. If we come to inquire what are the special circumstances which have led to Pasteur exerting this extraordinary influence on so many different departments of science and of practical life, we must attribute his unique position in the first instance to the possession of a singularly active, clear, and original mind matured under the strict discipline of an early training in mathematics and the exact sciences, which fitted him to successfully prosecute the profoundest researches in molecular chemistry, whilst by this severe exercise, in which he was exclusively engaged until his thirty-fifth year, and by means of his marvellous powers of accurate and minute observation, he was in his later investigations enabled to submit vital processes to such a rigid, logical, and uncompromising criticism as biological phenomena had not hitherto received. But even this rare combination of natural and educational endowments would have availed but little had there not been united to them an almost superhuman industry, an almost limitless capacity for work, for when we contemplate what Pasteur has accomplished and the overwhelming mass of labour on which his achievements rest, we are indeed forcibly reminded of the French proverb: *Le génie c'est la patience.*

It would be difficult also to find a better illustration of the manner in which one science can benefit from contact with another than that which is furnished by the results which have attended the digression of the specially trained chemist, Pasteur, into the fields of biology and medicine. Unfortunately such digressions, even when they are attended with mighty consequences like those which I have been endeavouring to set forth, do not always receive the welcome that they should command, for it is surely significant that as late as the year 1888 it should have been possible for a Paris correspondent to write: "Pasteur is a Commander of the Legion of Honour, possesses fifteen other decorations, is a member of eighty-three foreign learned societies, and holds the honorary doctor's degree of nearly every foreign university, and yet he is not a Doctor of Medicine of any faculty."

Whether or not he has been made a doctor of medicine since 1888 I do not know, nor is it a matter of any consequence, for it was assuredly without any such qualification that he set in motion that great medical revolution which has been well sketched by a modern French writer:

"When man learnt how to protect himself from the wild beasts he made the first step in civilisation. To-day man is learning how to defend himself from microbes—it is a step of equal importance. A day will come when in Berlin, in London, in Paris, man will not die of diphtheria, of typhoid, of scarlet fever, of cholera, or of tuberculosis any more than he dies in these cities to-day of the venom of snakes or of the tooth of wolves."

GUY'S HOSPITAL.

OUR PROFESSION, OUR PATIENTS, OUR PUBLIC, AND
OUR PRIDE.

By G. H. D'ARNA.

Medical Officer of Health for Buckingham.

It may seem to many, but I hope not to all, to be somewhat a waste of time to consider the relationships between the profession, the press, and the public. I would ask you, in the first place, to beware of appearances in all that concerns us, and especially in the apparent relationship between the public and ourselves, particularly at a time when too many of us while boasting of our power, popularity, and know-

ledge, leave the diagnosis of every "serious" case to a consultant, and its treatment to a trained nurse. Popularity has its dangers, and I well remember being told by the late Dean Stanley, "Popularity is all very well if you can get it, and if it comes to you, but you must never run after it." Public support is fascinating but fickle. In times of war soldiers are the pets of the people (and, however strange it may sound, I include all classes in that term), but in times of peace "doctors" are the fashionable craze. Society, "for-aking even military men," throws her charms to great wealth, successful humbug, the drama, and the medical profession. We should warn ourselves against judging by appearances, especially those which are nearly always deceptive. Let me take a somewhat out of the way instance to show what I mean. It is often said, "He does not know his own mind." Of course not. No one knows his own mind. It is one of life's purest pleasures to make its acquaintance. We know the existence of our own minds and we infer the existence of mind in others. Far, far away from actual consciousness there appears to be a laboratory in which the influences of our environment and the impressions from and in our organisms are received. Much is there stored and some is poured out into the mind, and oozes therefrom as we think, and speak, and write.

It is, indeed, delightful to find out by thinking, writing, or speaking what is "in our minds." It is a useful habit to acquire, because it cultivates the rarest and best characteristics of a medical man, namely, observation. I submit it is necessary for us to see what we are and to see what we are doing, but how rarely we do see. We look but we do not see. We do not see our work, nor ourselves, nor how others see us. Again, look over a landscape of undulating country, with its varied forms of green, its play of colours lit with the great, grand, golden glory of the sun. What do we see? Is what we are looking at merely the veil that covers a continuous crusade or a continual competition? Is the peace of its intense loveliness a mere film hiding the presence of everlasting war? Is the beauty of Nature only the expression of successful cruelty?

Again, turn for a moment, and ask yourselves if the apparent calm of humanity is only what covers, but does not really conceal, the constant and, may I add, cruel struggle for existence? Is it true nowadays when every man poses as the friend of all men, that man's inhumanity to man makes countless thousands mourn? Now you will ask me. What are you driving at? Simply that we must beware of our relationship to the public, and see to it that it is a true and honourable position for us to occupy, simply that we should learn not merely to look, but to see men and women and all things as they actually are and not only as they appear to be, for "All things are not what they seem," and no man and no thing is what he or it appears to be.

So, indeed, and too often, the appearance of hypocrisy or of honesty in our lives resembles the appearance of Nature where peace is but war and beauty but hidden ugliness. We do not only require lucidity in our view of the outside world, but lucidity of expression in the use of medical terms. Surely we must learn to see men and their maladies as they are. Who can say that there is a scientific uniformity of meaning in the medical terms which we use, and I think too freely use, to the public? Or even in that process of labelling symptoms with a name which is the plan by which we cheat ourselves that we are misleading others? Do you expect to find the same illness—if such a thing ever occurs—treated in the same way at different hospitals? Perhaps, however, that is only because one star differs from another star in glory. The expressions of medical science are characterised not by their lucidity but by their looseness. Let me give you an illustration. Think of the inconsistent, unscientific, contradictory, and frequently silly position ascribed to "cold" as a factor in the production of disease. Cold is given by a modern writer as the "predominant partner" in the causation of the following maladies (among others): Croup and tetanus, acute rheumatism and locomotor ataxia, diabetes and pneumonia, acute nephritis and infantile paralysis. Again, a distinguished London doctor, *magnum atque venerabile nomen*, writes to me by one post to say that a certain person is suffering from eczema, and that the treatment must be directed "towards its microbic causation,"

and by the next post advises me to tell my patient to avoid exposing her beautiful face to the sun, as that exposure "may produce an attack." We need not pretend that we do not value public esteem and confidence, but what steps do we take to deserve either when we hide our ignorance or our knowledge under loose terms? The fashion has not yet died out of labelling as "hysterical" any group of symptoms which are inexplicable on known physiological grounds, and this at a time when we do not know with certainty either the real effect of a poultice on the skin or the functions of the liver. The modern student, especially if recently qualified, regards as "neurotic" all the symptoms which do not come within the range either of his reason or his remedies. How do too many treat the conditions which they call "neurotic" or "hypochochondriacal," meaningless epithets that are used either with that haughtiness which is a proof of ignorance, or with that pity which is only another form of the same narrowminded contempt? First of all they deny the existence of the malady, then they say "there is nothing the matter," and when the patient recovers under the treatment of a man who is a physician without being a fool, they then sneer at the successful colleague as a man "who humbugs his patients." A section of the profession, notwithstanding all its post-prandial sentiment, is jealous of success. Surely it is utter nonsense because it is absolutely unreasonable and deplorably unscientific for a person to be ill and well in the ordinary senses of the terms, or that anyone (apart from very definite conditions of malingering) can "imagine himself ill." People who are ill are ill even if we do not understand the illness, and even if we cannot treat it.

Let me give one more instance, because it is one which more obviously affects our relationship to the public and our patients. I refer to our unfortunate habit of separating "functional" from "organic" maladies. Function is the expression of organic change and functional disorder is inconceivable without organic disturbance and change, and the latter is not the least but the most important factor, even if unrecognised, in those disturbances of health so stupidly called "only functional." It is more conceivable to think of organic change without functional disturbance than of functional disturbance without organic change. Why is all this? Why do we talk thus to the public, and to our patients, and to ourselves? Why do we rely on appearances and vague terms? Why do we thus lose, or deserve to lose, public confidence? Because in hospital life and training we fail to note the value of seeing life as it is, people as they are, or the true meaning of terms. In hospitals we learn about disease, but in practice we have to treat a person with an illness. Large numbers of "cases" (or diseases occurring in persons) pass under our observation in hospital life, but we only see the diseases not the persons, not only that, but both the person and the malady are removed from the conditions which would otherwise act on both. Not only that, but the greater part of our hospital life is spent in studying just those maladies, which, however important as types, are least often seen in general practice. In hospitals we see, or rather look, at others treating an illness in a person, but in practice we have ourselves to treat a person with an illness. We rarely see those deviations from what we call health which we have to treat in general practice.

We thus do not see before we get into practice our work as it really is but only as it appears to be. Our teachers, to whom no one is, or ought to be, more grateful than I am, are men who are what they are because they have been successful in hospital practice or distinguished for successful industry, and these men pass, and perhaps rightly, from the hospital to Harley Street, but they see little or nothing of ordinary general practice or the "cases" which we as general practitioners have to treat. They teach hospitalism and practise it. Men who have, therefore, to deal with patients, or the public, that is to say, start in practice are lost to some extent, have no power—because they have not the knowledge, which is power—to conduct a case, know not how to treat their patients or their patients' friends, cannot even behave themselves in a sick room—in fact many men only go into a sick room for the first time after they are qualified. We must remember that the proper study for the medical man at all events is man. A hospital is no more and no less the place to learn the diseases of mankind, so far as the rela-

tionship between patients and medical men are concerned, than are the zoological gardens the proper place in which to learn or to study the natural habits of animals. Much can be found out at either place, but, as at the zoological gardens we see animals under unusual or unnatural conditions, so in hospitals we see illnesses and people separated from the conditions by which they are both surrounded when we as medical men have to treat them. These considerations affect the public as a body and the public individually, or as our patients as we call them, and I would speak of the latter first. A patient expects that his medical man should be something more than a mere medicine man, that his doctor should be more than a detective to discover some pathological flaw in his health, something more than an accountant to bring out the balance of a diagnosis from the "complicated accounts" of his symptoms.

The public also expect much, and perhaps too much, from its public professional men in the protection of "health." To us, of course, health is only a relative term, but to the public it is an attainable reality. I have never seen a case of health, and I should like to see a really healthy man, woman, or child. And it is, by the bye, in the detection of the insignificant departures from an indefinite standard that the skill of a "doctor" lies. We do not treat the public fairly in the matter of health. For instance, we say "disinfect," but there is no reliable standard either of disinfection or a disinfectant. Again, people want to know what to do "in cases of illness," emergencies, and "epidemics." What do we do? What does the profession do? It supplies the public with scientific beef-tea not in tins but in lectures; it attempts to boil down the hard bones of science to suit the digestion of the public intellect, it floods the press not only with watery but adulterated solutions of science, while essences of surgical treatment and tabloids of medical knowledge are manufactured wholesale for general consumption. We want to appear to know and to make others like unto us. This is what is called and appears as the popularisation of knowledge, but in reality it is the prostitution of science. No doubt a knowledge of the laws of health can be taught (the means by which homes should be kept clean and filth removed from the person and the house, the advantage of light, air, and the diet of children), but amateur medicine and surgery are less reliable than the professional articles.

We think we are to teach our patients and the public what we know. If so, they must learn as we do. If our methods of teaching the public are right, then our own methods of learning are both wrong and useless. We allow the public to think we can dispense clinical therapeutics for them. People demand the knowledge how to treat illness, and we supply "a lecture" or a "course of lectures." I have often, and I do again beg to protest against such "apparent teaching," against the policy of sprinkling the community (by means of a more or less oratorical pepperbox) with tit bits of knowledge, whether pathological, physiological, obstetric, or hygienic. There are no such short cuts to knowledge. The appearance is not the reality, and as we learn so should we teach, and not otherwise. A desire to know is admirable, but the public are nowadays too inquisitive about illness. Our national manners show a deplorable lack of taste and good feeling in the presence of illness. If a man consults his lawyer, he does not find all his friends asking him, "What is his business?" or "Why did he seek legal advice?" Let such a man, however, consult his doctor, and at once all his friends and acquaintances—sometimes, perhaps, out of kindness, but oftener out of curiosity, or in the case of a celebrity out of a feeling of snobbery—at once rush to know what his business was with his doctor, and why he sought medical advice. It is sad to have to add that even the doctor himself is asked "concerning the case," and it is a shameful thing to have to admit that the information is often granted. The near relations of a patient may be told the nature of an illness, but without the express sanction of the patient or his closest relation no medical man has any right to make any sort of communication to anyone else, or even, I submit, to the medical press. The so-called upper classes, or certain sections, have, let us not forget, brought advertisement to an art. It is time we did something to protect the privacy of the home, especially of the sick room. To publish clinical details, or to throw the sop of a temperature chart to the gossiping wolves,

to make the sick room a market for advertising, are practices which are too disgusting and far too common. We all know the twaddle which is talked in the profession about advertising, especially by the sort of man who, swearing he would never advertise, advertised. Our medical press bids fair to become the mouthpiece of the would-be successful traders and of the professional Pecksniffs and Chaddbands. For instance, the contribution of cases is intended to advance knowledge, not to puff practitioners. We must look up to our press, but it should represent all that is most dignified and all that it is best. Look at the view which is taken by the medical press (and of course I am only speaking of some papers) on any subject of general interest, such as vaccination. The coarsest, the rudest, the most insulting language, is considered too good for those who, though supported by men of science and undoubted honour, feel a conscientious objection to compulsory vaccination. Dictation is not dignity, and the policy of kicking your opponents to death should hardly be the characteristic of the wonderful and advanced medical knowledge of the nineteenth century. We must bear in mind that the lay press is ever struggling to get personal details. It is, I submit, a national calamity to see the honour, purity, and responsibility of the press stained, and even in some instances washed away, by the muddy waters of competition. The necessity for paragraphs begets inaccuracy, and belief in the papers is becoming a sure sign of credulity. It is sad, indeed, to see the reckless manner in which that pompous person, "our own correspondent," not only endangers the peace of nations by his highly-coloured and self-imagined crises, but violates the privacy of home life by the publication of details of illness which are generally inaccurate and always inexcusable. We as a profession must not worship the golden calf of the "press" too much. From what I see and hear in London, not only the press but the profession is giving way before the rising and surging waves of competition.

I may point out that although some say competition creates commerce, yet others say it curses it. Must we, however, use such an argument? We must, I feel, if it is true that men who ought to know better, and who occupy "high positions," are not ashamed to steal other men's patients, or to be consultants at one part of the day, physicians another, surgeons another, specialists another, general practitioners another, while all the day long they violate those rules of professional honour to which they do homage only with their lips and not with their lives. These are the men who undermine confidence with "all the kind mendacity of hints," or with a silence more suggestive than speech. When people ask for "another opinion," what they want oftentimes is a "different opinion"; and they very often get it, for how many men allow themselves to be privately interviewed by "friends," and receive fees for such interviews when the conversation turns on "the recent consultation?" These are the men who undermine our press and our patients, and force so many of the public to look upon us as money-grubbing humbugs. These are the men who "get practices" by a "swagger turn out," by grand-looking houses startlingly painted, by large parties, by gorgeously-dressed wives, or by pandering to the barefaced snobbery of modern society. We must not imitate the methods by which sycophants succeed. We should value public confidence but we should also deserve it; we should wish for respect, but we should not get it under false pretences.

All the world is filled with loud praises as to "the advancements" in the prevention and treatment of suffering; but novelties are not necessarily improvements, as revolutions are not always reforms or reforms always revolutions. The light which competition in the press throws into the privacy of the home also finds its way into the laboratory, and the discovery of yesterday is trumpeted as the mark of an epoch. We are thus apt to follow fashion and fads rather than facts. I well remember, only about ten years ago, when I had the great privilege of being a student at Guy's—and I think every medical man should be a medical student all his life—that the profession was suffering from a very acute attack of the "spray." I know one distinguished surgeon who was almost "cut" by his colleagues for not using it. How different now!

The profession is now suffering from convulsive attacks of

bacteriology. When I left Guy's the spray ruled surgery; now we all worship germs. In the interests of truth we should appreciate and not exaggerate the relative value of all parts of science. I will only simply allude to "the importance of serum therapeutics," or of the policy of quieting the pathological Paul by extracts from the immunised Peter.

Every problem is discussed in the press, and, owing to the habit of pseudo-philosophical generalisation from insignificant details which now characterises modern journalism, the public and our patients are misled. In these days, when the fierce light of publicity beats around a test tube, we must not so quickly take the public into our confidence, especially in the press. Our duty is to look for the truth, not to encourage competition. Our patients are led to think they know so much, and therefore, when an illness arises, they now make the diagnosis and decide on the treatment and the proper specialist to consult. The first question a lady asks when she hears her servant has got rheumatic fever is, "Can she take salicylate?" We know very little, but the public knows less. People now have one medical man for every organ, and I know a lady who consults one man for her eyes, another for her throat, another for her "chest," another for her menstrual troubles, and she herself decides "what is wrong," and then asks me to reconcile the contradictory pieces of advice which she gets from "her London doctors."

The false relationships of our public and our press and our patients to our profession are our own fault. Let us think less of our successes and more of our failures. Less of the possible glory of the future and more of the darkness of the present, less of our modern advances and more of our modern helplessness, less of the possibilities of science and more of its simplest theories. Are the foundations of our knowledge sure? Do we know for certain the functions of any organs of the body? Are we adding to or lessening human misery and woe? Is our science a tower of Babel? I believe we shall do best if we do right, and we shall do right if we recollect every hour of our professional lives not merely our advanced knowledge but our appalling and lamentable ignorance. I want to show that we should not fix our eyes only on the advancing waves, especially as waves have a knack of receding, that we should not be led away by our apparent popularity and power, that we should simply do what is right and not ostentatiously act as if we knew so much more than we do. Our knowledge is vast but our ignorance is vaster. It is easier to explain away a symptom on the principles of a sort of 4 o'clock tea kind of physiology than to treat the conditions to which the symptom may be a guide. As a profession we must not puff nor be puffed up. We are getting too proud. The ruling monarch of the world, namely, ignorance, has ever had dognation and cocksureness as his equestrian waiting permanently on duty. We rush like a lot of sheep at every new therapeutic fad, and sneer at the wary and wiser public for their indifference.

Science loses nothing and gains much when it combines with sense, and the medical man does not know less of diseases if he knows something of human nature. Those who have to treat people who are "ill" should study those who are "well." We should value character more than a certificate and a real success more than an apparent victory. We should be as men treating other men not as hospitalised beings treating patients. In all our relationships we should remember that kindness, gentleness, and sympathy add to the true value of skill and that though the powers of the head are great the powers of the heart are greater. We can do much by our abilities but more by our affections, and although we now have "to live in wearied hope," yet it is not the possible only but the perfect we should live for, ever bearing in mind that "greatness is to take the small things of life and walk grandly among them."

SWISS SANATORIUM FOR PHTHISIS.—It is hoped that the sanatorium for poor phthical patients at Davos may be ready to receive from fifty to sixty patients in July next. The subscription list now amounts to over £13,000. The municipal body of Davos intends also to erect a sanatorium in the neighbourhood of that city for phthical patients applying at the hospitals.

ST. MARY'S HOSPITAL MEDICAL SCHOOL. THE MEDICAL PROFESSION AND UN- HEALTHY TRADES.

By A. P. LAURIE, M.A., D.Sc.,
Late Fellow of King's College, Cambridge.

AFTER some introductory remarks Dr. Laurie said that it had been his good fortune to be appointed a member of the Home Office Committee, which inquired two years ago into the results produced on the health of the operatives by pottery manufacture. Most of the local doctors of the district who gave evidence had little information to give. Evidently their attention had never been specially turned to the question and they had missed the opportunity afforded them of making a most interesting series of investigations. There were, of course, many noble exceptions. The name of Dr. Arlidge would always be remembered as a pioneer in this department and the researches of Dr. Oliver into the poisoning in white lead manufacture had pointed the road to be followed by others. But in spite of these men little had yet been done in the way of scientific inquiry with the view of remedying the evils produced under modern conditions of industry.

The laws protecting the labour of women and children and the regulations requiring cleanliness and ventilation had been of incalculable benefit to the industrial population, but the questions now arising were more difficult and did not lend themselves to a solution. The whole of the problems involved in the handling of poisonous substances and in the breathing of a dust-laden and vitiated atmosphere and in the working in excessively high temperatures were still in most cases awaiting solution. The Home Office had made vigorous efforts to deal with some of them by special inquiry and special rules but the result of these inquiries had been to state clearly the problems awaiting solution but not to solve them.

In order to make clear the present state of affairs the history of factory legislation was sketched briefly, starting with the great Consolidating Act of 1878. This Act may be roughly divided into three portions: (1) The portion regulating the hours of employment of women and children and young persons, the ages at which children might be employed, and their proper education. There was nothing in this portion which could not be efficiently administered by good inspectors. (2) The portion dealing with the notification of accidents and the fencing of machinery. Here some expert knowledge would be advisable, and many mistakes had been made by inspectors for want of it, but the principles to be applied were simple, and no serious difficulty had arisen. (3) The clause dealing with the sanitary condition of the factories and workshops was as follows:

A factory shall not be so overcrowded while work is carried on therein as to be dangerous or injurious to the health of the persons employed therein, and shall be ventilated in such a manner as to render harmless, so far as is practicable, all the gases, vapours, dust, or other impurities generated in the course of the manufacturing process or handicraft carried on therein that may be injurious to health.

This clause laid down a most important principle, but on the other hand was so general as to make it most difficult of application to particular cases, and to make the task of the inspector required to enforce it a most invidious one. This seemed to have been already recognised, as special rules as to privies and as to cleansing and whitewashing factories were introduced; and, furthermore, certain definite industries were mentioned in the Act. There were special rules with reference to bakehouses, and the inspector was empowered to require mechanical ventilation in the case of dry grinding, and to require proper protection from wet for the spinners in flax mills. Furthermore, certain unhealthy trades were scheduled, in which young persons under 16 must not be employed, and in other trades meals were forbidden in places where certain processes were carried on.

The next step in advance was the Act of 1883, which laid down special rules for the regulation of white lead factories, and additional rules were made for bakehouses. Gradually the vague recommendations were being replaced by definite rules to meet specific cases.

The next step was taken in 1889 in the Cotton Cloth Act. Here for the first time the condition of the air breathed was

dealt with definitely. Under this Act a table of percentages of moisture in the air for each temperature was laid down. This extraordinary interference had apparently been most beneficial. It had necessitated the artificial ventilation of the weaving sheds on the most scientific principles, and apart from the questions of health involved, had actually, as Dr. Laurie had been assured by a large Lancashire mill-owner, improved and increased the output of the looms. In the Act of 1891 two further important alterations were made. The sanitary condition of workshops as apart from factories was removed from the charge of the factory inspector and put under the local sanitary inspector, an alteration of doubtful utility, and another advance was taken in the detailed regulation of the health conditions. Under the dangerous trades clause of this Act the Home Office was given the widest powers. It had no longer merely to administer definite clauses in an Act; it was made directly responsible for the health of the workers, and was called upon to devise means for their protection, while, on the other hand, it was given powers that might prove most harassing to industry. Just after this Act was passed Mr. Asquith became Home Secretary, and found himself face to face with the problem of administering this clause, and with an outside agitation in favour of its enforcement. To attempt to draw up special rules for various dangerous industries was impossible without expert advice. He therefore appointed mixed committees of factory inspectors, medical men, and men of science to report on certain industries. The industries first selected were: White lead, soda and bleaching powder, pottery, colour, linen manufacture, and stone quarrying.

On the reports of these committees special rules were devised and applied to these industries, while it was furthermore found necessary to include certain of their recommendations in a further Act of Parliament passed this year.

This Act extended the control of the Factory Department to new industries, stiffened up the regulations of former Acts, defined accurately conditions formerly left vague, extended the regulations as to humidity and as to artificial ventilation to new industries, required proper regulation of temperature, and finally gave the Home Secretary power to forbid or limit employment in dangerous trades. All these provisions increased the responsibilities and difficulties of the Home Office in dealing with these sanitary questions.

The Home Office, Dr. Laurie continued, had been rapidly acquiring very heavy responsibilities and complex duties with reference to protecting the health of the workers, and these duties were of a kind which could not be satisfactorily fulfilled by the ordinary staff of inspectors.

The reports of the Special Committees were worthy of study by all medical men interested in public health questions, and contained a great deal of interesting information, but the information obtained was inevitably imperfect, and the proposed remedial measures were in many cases of a tentative character. In fact, in the report by the Potteries Committee, this was brought out very clearly by the Committee themselves. They asked "to be empowered to continue their investigations as to the composition of glazes and colours with a view of finding out how far it is practicable to make a glaze that shall be harmless to those employed, and at the same time shall not injure the ware." In another paragraph they said: "Further information is also required as to the temperature of potters' workshops and of stoves at the time of drawing the ware." Further on, speaking of the same subject, they said, "We have already in Rule 7 attempted to deal with the temperature of workshops, but do not consider the rule in its present shape as final," and so on. Similarly, the reports of the other committees were full of suggestions as to modifications of machinery and processes which would result in far more benefit than many of the special rules, and which, when adopted by manufacturers, should be carefully watched and reported on from time to time, with a view, if successful, to their ultimate universal adoption.

Zealous and efficient as the factory inspectors are, Dr. Laurie continued, they cannot be expected, overburdened already by the increasing number of duties they have to perform, to be able to observe what the effects of the special rules are on the health of the operatives, or to discover which are of value or what modifications are necessary; for,

apart from the fact that they are already overworked, such observations require a medical training.

As an example of a case where scientific observation is required, Dr. Laurie took the Cotton Cloth Act, requiring the regulation of the temperature and humidity of the air in the weaving sheds. This Act has produced a complete revolution in the methods of ventilating the weaving sheds, and gives the opportunity of studying on an enormous scale, the results of artificial ventilation on the health of thousands of people, and the value of the new methods as compared with the old.

A careful recording of this experiment would be of the utmost importance in guiding us in the ventilation of factories and schoolrooms, and yet, as far as I am aware, no one is watching and recording the results; or, if it is being done, some private enthusiast is engaged in the work, and the Home Office having instituted this interesting alteration on the air supplied to thousands of operatives, with a magnificent carelessness does not even watch and record the results of its own experiment. The same criticism applies to the special rules which have been applied to other trades, for they all involve regulations introduced to affect the health conditions under which the operative works, and yet no observations by experts are being made to see if they effect their purpose. We have, therefore, most valuable experiments being made upon this most important subject without any proper record or criticism of the results.

Questions are arising and will arise in connection with these special rules and the various modifications of manufacturing processes which are always taking place which the Factory Department of the Home Office, having no experts to apply to, are incapable of solving. I know of one case where a manufacturer applied to the local inspector to be relieved from certain special rules because of certain modifications in processes of manufacture, and the question was referred by the inspector to the Factory Department, referred by the head of the department to the Home Secretary, and by the Home Secretary to the local inspector, and by the local inspector to the manufacturer, who, being the only expert in the whole chain, gave judgment on his own application.

What is required to enable the department to deal with these questions of increasing difficulty, and to advance further in its battle with disease and death? There are two proposals which I should like to make, proposals dealing with the central and the local organisation respectively.

In the first place, to deal with the local organisation. There is a body of men to whom I referred in the beginning, the certifying surgeons, of which sufficient use is not being made. The certifying surgeon is appointed by the factory inspector of the district. He has to examine all children and young persons in his district who are about to be employed in factories, and without his certificate of fitness they cannot be employed. For this duty he receives from 2s. 6d. to 7s. 6d. for each visit, and 6d. for each child examined over five in number, when the examination is made at the factory, and 8d. for each child when at some place appointed by him. This is done only in cases when the number of children is under five.

In the second place, accidents must be notified to him, when he must make an inquiry, and has a right of entry into the factory for this purpose. A special fee is paid for this also. Would it not be possible to employ the certifying surgeon to make continuous observations on the health of the operatives and the effects of new regulations and report to the Home Office on the same, and would not the money so expended be well spent, and is it not worthy of consideration whether the status and method of payment of the certifying surgeon could not be improved? I know of one certifying surgeon who has received exactly 2s. 6d. in fees in three years. In return he had to fill up innumerable forms and reports to the Home Office. This can hardly be regarded as a lucrative appointment. In fact, we have here an expert staff already in touch with our factory system and responsible for the fitness of the operatives at the beginning of their career which might, if properly encouraged, supply us with invaluable information; and furthermore, in the Factory Act of 1895, a clause has been introduced giving power to the Home Secretary to call on the certifying surgeons to make special inquiries, which opens the door to my proposal.

But it is not only locally that the expert is required; the work done by the temporary expert committees appointed by Mr. Asquith has shown the value of expert advice. Why should not the Home Office have an expert consultative committee attached to the Factory Department consisting of doctors, manufacturers, men of science, and engineers, who should have power to inquire into and report on and advise on questions affecting the health of the operatives? In this way much useful work could be done.

I am sure the manufacturer would welcome my proposal. He too often feels now that he is subjected to vexatious regulations involving trouble and expense, but which do not go to the root of the matter, by a department which, though well meaning, is ignorant. Such an expert committee would give him more confidence in the Factory Department, and make him submit to their conditions with better grace.

It is therefore in this direction that I venture to think the next step in advance is to be made; and in conclusion I would wish to press upon our future doctors the importance of these questions. Noble as the work of curing disease undoubtedly is, that of preventing disease is nobler, and there are many thousands in our great manufacturing cities the victims of our industrial conditions, living lives of hopeless ill-health, who are looking for deliverance, a deliverance which is only to be obtained for them by men who combine the calm, clear intellect of the man of science with a burning compassion for the sufferings of their fellows, a combination of qualities which is to be found most frequently in the medical profession.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.

ON THE METHODS OF MEDICAL STUDY.

By W. JULIUS MICKLE, M.D., F.R.C.P.Lond.,

Lecturer on Mental Physiology and Mental Disease to the Hospital.

THE address was chiefly devoted to discussing the manner in which our knowledge of a simple external object is obtained and in drawing from that conclusions as to the only proper, natural, and fitting methods of medical study.

In the first place it was shown that in the mental development of children the acquirement of a knowledge of a simple object is a gradual affair, and only succeeding after many attempts. That simple as it may appear, it is only arrived at gradually, and after failure of the earliest attempts, so that only little by little is the knowing achieved; and any very early error must be corrected by subsequent experience, so that there is a process of learning, and of overcoming difficulties, in order to know the simplest object.

Applying this to medical studies, it was pointed out that, in order to be natural and fitting in method, the process must be gradual; that it must begin with the most simple, which must be thoroughly mastered before the study of the more complex is undertaken.

In the second place, in knowing a simple object of a certain class there must be a synthesis of the evidence derived from each sense concerned and a conjunction of that of the several senses co-operating in the process of knowing. The importance of the sensations of sight, of touch, and of those attending movement was indicated, and the inextricable manner in which the feelings of movement are bound up with the visual and tactile was insisted upon. The importance of the movements of the eye and hand in vision and in active touch was referred to, and the sensations derived from other senses, such as hearing, taste, and smell were shown to have their part in the process of perception of the particular object which was made use of in illustration of this part of the address.

In the application of this to medical studies it was maintained that in them it is necessary, as far as possible, to use all the activities of mind, and in co-operation. In relation to this the importance of great width of culture in medicine was asserted, and the characters were mentioned which any sound specialism must possess, and especially that it must be built on the firm foundation of a wide and complete study of medical and other sciences. In relation to this, and as examples to follow, were mentioned the wide bases on which were built the medical acquirements of two eminent members of the profession recently lost by death—namely, Mr. Hulke,

who, besides profound knowledge of general surgery, was also an expert in ophthalmic science, was of great repute in palæontology, and of very considerable attainments as a linguist. The other was the late Dr. Bristowe, who to a profound knowledge of general medicine had added a special knowledge of pathology, and of diseases of the nervous system, abdomen, and skin.

In the third place, for accurate knowledge of the simple object it was shown that there is a process of search for accuracy, a process (so to speak) of working towards truthfulness, so as to secure a truthful mental representation of the object, and to correct any error of sense by the truthful evidence of other senses. And, moreover, that what is true with regard to these simple products of mental activity is true also of the outcomes of all the higher, and the highest, activities of mind, and their collateral results, and involves the accuracy therefore of the highest thoughts or ideas.

This proved the necessity of using, in medical investigations, the utmost fidelity, the honest intention of truthfulness to Nature, and the necessity of correcting any error that may arise by the critical operation of other forms of mental action.

And, pursuing this part of the subject, the predominant importance of making medical study as faithful as possible to Nature was urged, as well as that in medical research and study there should be a perfectly unbiased, fair, consistent, judicial frame of mind, employing in its service all the modes of mental action, and honestly seeking to attain that which is true; that, in a word, medical study should be an honest, consistent, persistent search for truth, and made with all the powers of the student and practitioner.

Other topics relating to the main theme were briefly discussed.

THE WESTMINSTER HOSPITAL MEDICAL SCHOOL.

ANTITOXINS AND OTHER ORGANIC REMEDIES.

By S. MONCKTON COPEMAN, M.A., M.D.Cantab., M.R.C.P.,
Medical Inspector Local Government Board, and Lecturer on Public Health in the Medical School.

DR. COPEMAN commenced his address by paying a tribute to the memory of the late Dr. Octavius Sturges, who at the time of his death was Senior Physician to Westminster Hospital, and who had formerly held the position of Dean of the Medical School. Reference was also made to the still more recent death of Dr. Bristowe, a former teacher and colleague of the lecturer, and Consulting Physician to St. Thomas's Hospital. Between Dr. Bristowe and Dr. Sturges he said there was this point in common, that it had been asserted of both of them that they were wont to pay too little attention to the therapeutic treatment of disease. It was pointed out, however, that both were great believers in the value of good nursing and of hygienic surroundings; treatment by drugs, especially in absence of exact knowledge of the pathology of any particular case, being considered of secondary importance. Yet both were ever ready to accept and employ any method of treatment which could be shown to possess a scientific basis. Such methods were for the most part the outcome of experimental research during the last few years; and it seemed that a fitting subject for the remainder of the lecture would be a brief discussion of some of the more important developments of modern medicine, with special relation to the treatment of disease.

In this connection attention was directed more particularly to the employment of preparations of an organic nature, usually in the form of extracts of certain organs, in diseases in which these particular organs are affected, and to the bearing of bacteriological research on the diagnosis and treatment of specific infectious disorders. As the best known instance of the first method mention was made of the use of preparations of the thyroid gland in myxœdema—a disease in which the thyroid was specially affected. This organ was one of the group of so-called "ductless glands," concerning the exact functions of which, until recently, but little was known. Investigation had shown, however, that all these organs were, under normal circumstances, continuously elaborating substances, which are taken up directly into the

blood stream as it courses through the vessels of these organs. It has been shown by experiment that in animals deprived, for instance, of the thyroid gland, symptoms akin to those noticed in the disease termed myxedema supervened. Implantation of portions of the gland of another animal was therefore tried in cases of the disease in man and with satisfactory results. Later it was found that injections of extracts of the gland were equally useful, and, more recently still, it had appeared that simple feeding with the gland might be substituted for anything in the way of operative measures. Indeed, through the efforts of pharmacists, simplicity of treatment combined with accuracy of dosage had been brought to such a pitch of perfection that an ample supply of the medicament for several days' treatment could now easily be carried in an ordinary pillbox. Extracts of several other organs had been employed in somewhat similar fashion in the treatment of disease involving these particular organs, but as yet experience of their use was insufficient to enable any very definite opinion to be expressed as to whether they might eventually prove of equal value, but there appeared good reason for believing that such might turn out to be the case.

With regard to the aid afforded by bacteriological research in the diagnosis, and more particularly in the treatment of disease, it was worthy of mention that since it became known, through the labours of Pasteur, Koch, and others, that certain of the specific infectious diseases were related to invasion of the system by definite micro-organisms, it had been found possible to diagnose the presence of such diseases as diphtheria, pneumonia, and tuberculosis, often at quite an early stage, by demonstrating the presence in exudations or secretions of a particular bacillus or other microphyte. The attempts at specific treatment of bacteriological diseases had advanced by three very definite steps. The first of these was the inoculation of attenuated cultures of the organism concerned, a method introduced and successfully employed by Pasteur for the preventive treatment of anthrax and chicken cholera. Although, of course, not appreciated in such at the time of its introduction by Jenner, vaccination was, in all probability, an instance of the application of this method. Next it became known that the moribund action of bacteria was, in many cases at any rate, due to the manufacture by them of poisonous matters or toxins from the pabulum on which they lived. By employing these toxins, previously freed from organisms, for inoculation instead of the actual bacteria themselves, it was found that the dose was capable of more accurate estimation, while at the same time the protection afforded was in some cases equal to that resulting from the use of an attenuated culture of the organism itself. By far the most important, as well as the most recent stage was that which has been marked by the introduction of an antitoxin for certain of the diseases in question. Behring, in the case of diphtheria, discovered that when an animal had by repeated inoculations with the toxin been rendered fully resistant to the disease, the blood serum of such animal, when injected into the system of another, conferred on this second animal also a power of resistance against the disease. On similar lines antitoxins had been devised against tetanus and against that numerous class of diseases which—like erysipelas, for instance—were believed to be due to invasion by streptococci.

The lecture concluded with a short account of Dr. Copeman's own work in connection with small-pox and vaccinia. The results obtained appeared to show that the specific organism in both these diseases was a small bacillus, which stained with great difficulty. It could also be cultivated in a special medium, though with even greater difficulty, and calves had been successfully inoculated with such cultures. It seemed not unlikely, therefore, that in the future we might, in addition to the protection afforded by vaccination, have a means of combating the invasions of small-pox when the system had actually become invaded by the disease.

The new interim Governor of the Rio Negro territory of the Argentine Republic is Mr. George Humble, a son of Dr. Humble, medical missionary at Viedma. Mr. Humble, who is only 27 years of age, was born in Viedma, and, though an Argentine, is said to retain all the characteristics of the Welsh stock from which he comes.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

THE STUDENT'S CAREER.

By CHARLOTTE ELLABY, M.D.,
Ophthalmic Surgeon, New Hospital for Women.

Miss ELLABY began by reminding the students of the legend of the House of Busyrane, comparing the treasure of knowledge to Love's prisoner, well guarded within the House by seven iron doors, for which each one must find the key for himself. She said: Over each door was an inscription—over the first, "Be bold;" over the second, "Be bold, be bold, and everywhere be bold;" but over the third came a sudden check, "Be not too bold." In the search after medical knowledge, students would do well to adopt these mottoes as emblems of the courage, tempered by wisdom, required to seize and to put to its best use this treasure when found. But "Life is short, Art is long," so, in addition, haste was needed, but with the same check, not too great haste—*Festina lente*, make haste slowly. This triple armour—courage, wisdom, and speed—would prove all-sufficient for any battle. The study of medicine should, like all other kinds of education, be "brave and preventive." For this the all-round development of the whole nature was needed, which would give the power to grasp all details of a question, and to approach it from a higher level; in this way the judgment would be divested of every personal element, and the physician would be enabled to act without vacillation or delay. Very close to this came the question of relation with other people or manners. These should be "the happy way of doing things," and this "happy way" helped towards the cultivation and possession of a real sympathy with others, one of the keys with which to unlock the secrets in Nature. This sympathy also renders us tolerant and large-minded enough to appreciate other people's opinions and judgments even when they differ from our own. On the importance of health, especially in connection with the bugbear of overwork, "others' follies teach us not," and each must fight her own battle; provided only that the experience gained did not come too late, and that the precious Pegasus of health was inside the stable and not outside when at last the door was shut. There was a temptation besetting every earnest student at the outset to spend too many hours consecutively in work. The attempt to accumulate many facts was only satisfying for the moment, for facts must sink into the mental soil and not lie on it. The object of study was the cultivation of reason as well as of understanding; the mind, therefore, should not be overloaded with facts, but the facts should be regarded as a means to an end and not the end itself. Above all, the time spent in recreation and outside work should not be grudged, for it was then that the larger and fuller views of life came. The advice the Emperor Alexander gave to the Poles, "Above all, no dreams," was not good for general application, for in the somewhat prosaic details of daily life they came as a help and not as a hindrance, if they were kept in a right proportion to work or action. Time should be given to recreation, thought, and meditation, and even dreaming. It had been said that the tragedy of all souls lay in the gulf which separated ambition from its realisation. Opportunities must not be let slip, but seized at the right moment; for "Occasion," says Bacon, "turns a bald noddie after she hath presented her locks in front and no hold taken." There is surely no greater wisdom than well to time the beginnings and onsets of things. It is perhaps too fatalistic to say that "character is destiny," but it is nevertheless true that destiny is very much what character makes it. It was not in the power of everyone to be a genius, or to make a mark in the world; but it rested with each to make, as Jean Paul Richter had said, "as much of ourselves as could be made out of the stuff." This was only to be done by steady all-round work, and patient humble searching after truth. In this way each might endeavour to contribute her mite, not only to the use, but also to the beauty, of life. "All things are for the sake of the good, and it is the cause of everything beautiful." In conclusion, Miss Ellaby quoted the words of one of the greatest of philosophers, specially applicable, perhaps, to the student in medicine: "And, generally, it is good to commit the Beginnings of all great

Actions to Argos, with his hundred eyes; and the Eris to Briareus, with his hundred hands: First to Watch, and then to Speed. For the Helmet of Pluto, which maketh the Politicke Man goe invisible, is, Secrecy in the Counsell, and Celerity in the Execution."

YORKSHIRE COLLEGE, LEEDS.

OUR FOREFATHERS.

By D. J. LEECH, M.D. (Lond.), D.Sc. (Vict.), F.R.C.P.,
Professor of Materia Medica and Therapeutics at the Owens College,
Manchester.

IN his introductory remarks, Dr. Leech pointed out the high position of the medical profession in the body politic, and acknowledged our indebtedness to our earlier predecessors not only for a considerable amount of actual knowledge, but also for the initiation of those high ideas with regard to conduct which have happily become an abiding tradition with us. As to the origin of the medical profession, Dr. Leech referred to Mr. Herbert Spencer's article in the June number of the *Contemporary Review*, where this writer claims for the medical profession a sacerdotal origin. He points out that the union of the functions of doctor and priest is a normal trait of early societies. Ideas of the supernatural in connection with disease would naturally lead to the priest taking the function of physician as one who deals with ghosts not antagonistically but sympathetically. The priestly caste, he says, in an early state of civilisation, develops culture, and from part of this culture, having its origin in preceding stages, comes greater knowledge of medicinal agents, which gradually cease to be considered as acting supernaturally.

Mr. Spencer thus seems to be of opinion that treatment by remedial agents owes its introduction to ideas concerning the supernatural, that the priesthoods added to medical knowledge thus initiated, and that medicine and the medical profession of the present time have originated from the bases thus established by them. Dr. Leech considers this view open to some objections. Doubtless a very close connection has existed from very early times between medical treatment and the belief in the efficacy of supernatural means for the cure of disease. Indeed, even in the most civilised people, it still to some extent exists. But there is little to indicate that the initiation of the treatment of disease developed chiefly from such beliefs. Nor is there proof that the earliest practitioners of medicine were priests, or held views concerning the supernatural other than those which seem common to the early stages of man's development in all countries and in all times. The association of the priesthood with medical treatment does not seem to have been beneficial to the progress of medical knowledge but rather the reverse.

The origin of treatment of disease by remedial agents has been the subject of speculation from very early times. It has been thought by some to have sprung from the same instincts which seem to lead animals under certain conditions to eat, when ill, substances they usually avoid; others, for example, Schmiedeberg, have suggested that man has imitated the habits of animals in this matter.

In the treatise on ancient medicine included in the works bearing the name of Hippocrates, and which Littré believes were written by the Father of Medicine himself, the belief is expressed that medicinal treatment arose from observations on the different influence of foods and their properties in health and disease. In connection with this view, it is interesting to note that in the earliest works relating to treatment, dietetic substances play a leading part in remedial agents. The oldest document bearing on medical matters we possess was discovered in 1882, at Kahun, near the Pyramids of Illahun, in the ruins of an ancient town which had been apparently inhabited by the builders of the pyramids. It dates from the twelfth dynasty, B.C. 2700 to 2500, more than 1,000 years before the Exodus. A translation of it by Mr. Griffiths of the British Museum, will be found in the *British Medical Journal* of June 3rd, 1893. It consists of instructions for midwives, and includes prescriptions for treatment. Into these articles of diet largely enter—beer, cow's milk, oil, dates, and other fruits, herbs, sweet beer, honey, onions, etc.

In the prescriptions of the medical papyrus obtained by Ebers at Thebes, and usually bearing his name, the same feature is well marked. This most ancient of Pharmacopœias—for such it is—was found between the legs of a mummy. There is a general consensus of opinion that it was compiled about 1500 B.C., though some of its contents date from an earlier period. It consists of formulae for the treatment of a large number of ailments, both external and internal, some very simple, consisting of one or two ingredients only, others more complex, containing twelve to fifteen drugs, and directions more or less precise are given for their preparation and use.

Most of the drugs are derived from indigenous plants, but a few minerals, such as alum, salt, nitre, and sulphate of copper, are also found in them. Some of the ingredients cannot be recognised.

In the prescriptions of the Papyrus Ebers dietetic substances largely predominate; honey, milk, bread paste, several cereals, fruits, such as figs, plums, grapes, melons, and dates, and like substances are found in a very large proportion of the prescriptions, and that they were not used simply for flavouring purposes seems evident from the fact that some of the medicines are entirely composed of them; thus, for example, the second prescription consists of figs, plums, and sweet beer, and the third milk, bread, and honey in definite proportions.

It is probable, too, that in addition to the large number of substances in this Pharmacopœia which we recognise as foods, many of the other components which we look upon as drugs were used in ancient times for culinary purposes. Thus, for example, the leaves and seeds of the castor-oil plant are present in very many of the prescriptions; so, too, is the astringent sycamore fig. But Maspero points out that in the time of the Pharaohs castor oil was probably taken regularly in food; indeed, it is yet a favourite condiment amongst the Egyptian *fellahs*, who flavour their salads with it. The fruits, too, of the sycamore and many of the substances we regard as nauseous were in former days eaten. Maspero thinks that the Egyptians "began by eating every kind of food which the country produced. Many of these, when their therapeutic virtues had been learned by experience, were gradually banished as articles of food, and their use was restricted to medicine; others fell into disuse, and only appeared at sacrifices and funeral feasts."

In the drugs used by savage tribes, foods and substances capable of being used as such, predominate as they did in Egypt of old; and as was the case in Egypt, active poisons are comparatively rarely used as medicines.

As medical knowledge has advanced, foods have been for the most part replaced in the treatment of disease by more active agents, but they have not yet entirely disappeared. The lettuce and pearl barley with its preparation, decoctum hordei, are to be found in the list of remedial agents in the present edition of the *British Pharmacopœia*, and constitute a connecting link between the medicine of the present day and its origin in the dim past. It is not difficult to account for the prevalence of foods and the absence of active poisons in primitive medicine. The favourable change in certain forms of disease which follow vomiting or excessive action of the bowels, skin and kidneys, must have attracted the attention of man in the earliest stage of his development. In his search for food he would note in the first place the substances which when taken cause death soon, and these he would entirely discard. His attention would also be drawn to certain animal, vegetable, and mineral products, giving rise to vomiting, purgation, diaphoresis, or diarrhea, and even the most untutored mind would infer that advantages might follow their administration in those diseases in which emesis or an increase of the secretions had been found beneficial.

It seems probable that most of the earlier medicines were substances first tried as foods, and those which when taken in large quantities or in special conditions influenced the functions of the body; these, together with others found to be too potent for dietetic use consolidated for the most part the primitive Pharmacopœias.

The general employment in early societies of drugs which have definite effect on the organs and secretions is worthy of note. From the document bearing on medicine which was

written some 2,000 years B.C. it is evident that emetics were then given, whilst in the Papyrus Ebers there is a distinct recognition of the value of substances which cause purging, vomiting, and increased secretion of urine, and a recognition of such groups of agents is often a well-marked feature in the rudimentary therapeutics of uncivilised peoples. Now a medicine springing entirely out of magic, witchcraft, and the like, would not concern itself largely with foods, nor with such prosaic proceedings as purging and vomiting.

Though it seems probable the use of natural remedies originated for the most part from observations on the phenomena of disease, and the influence of substances tried in the first place for food, many other circumstances have, of course, led to the introduction of remedial agents. The cravings of patients during sickness for articles of diet not ordinarily taken, no doubt in earlier times led to their employment as remedies, as they do at times even now, and many other incentives to the trial of remedies in disease might be named.

The extent to which observation has led to the use of natural remedies in uncivilised countries varies much. The combination of fanciful ideas and superstitions with the use of natural remedies likewise varies greatly; these are everywhere present, sometimes they predominate. Nevertheless there seems no sufficient ground for the assumption that the use of natural remedies amongst savages is the outcome of the superstitious ideas which accompany it. It is easy to imagine that the definite effects which a drug is found to produce may be attributed to a spirit, but that the aperients and emetic drugs so often used by rude tribes have been originally given on the view that they possess a spirit seems hard to believe. The character of the earlier formularies and of those of uncivilised peoples points to an origin of medicinal treatment from observation, and it is from this that the medicine of to-day has sprung.

The earliest practitioners of medicine, Mr. Spencer seems to think, were the priests, but Dr. Leech considers that such scanty information as we can glean from the history of the earlier stages of society does not point in that direction. As we go back into Egyptian medical history we do not find evidence of a greater influence of the priesthood in medicine, but rather the reverse. The document discovered by Mr. Friedman Peirce only contains one incantation. It is true it contains domestic medicine, and only one department of this, but Dr. Leech's contention is that medicine of to-day owes its origin to a domestic medicine which is, and has been from earliest times, practised everywhere, and which did not arise from the magicians or priesthood. Anyway it is interesting to note that in the most ancient document relating to medicine, amid many old women's tales we find scanty allusion to the supernatural.

The Papyrus Ebers, compiled 1,000 years later, shows a greater intermixture of religious and medical views, but there is no evidence that the priesthood and superstition dominated as they probably did many centuries later. Medical knowledge at the time it was composed would seem to be the outgrowth of a highly cultivated domestic medicine, influenced, though but little injured, by a belief in gods and supernatural forces. There are some indications that domestic medicine was largely practised in Egypt in early times. The treatment of disease by drugs was widely diffused there. Ladies probably had their medicine chests as they now have. The domestic medicine chest of the wife of Pharaoh Mentuhotep, about B.C. 2600, is now in the Berlin Museum. It was found to contain six vases, one of alabaster and five of serpentine, with dried remnants of drugs and some roots.

A sentence in Homer's *Odyssey* is supposed by some to allude to the widespread knowledge of medicine in Egypt in early times amongst the laity. In alluding to Egypt it is described as a land producing many drugs, some good some bad:—

ἰατρὰς δὲ θεοῖσιν ἀντιπάλινος πέρι φάρμακον
ἀνθρώπων ἢ γὰρ Παιφονίης εἰσι γυνήεσσιν.

"Each one is a physician skilled beyond all men." There is, of course, not much evidence in all this, but as far as it goes it seems to indicate that from earliest times a knowledge of the action of remedial agents was widely spread and not confined to a priestly caste. There were also at very early periods

physicians who had a more special knowledge of disease and drugs. The grave of one, living from 3,600 to 3,500 years B.C. has been found.

In later times, especially in the decadent days of Egypt, medicine was in the hands of the priesthood, and superstitious practices prevailed. Domestic medicine was no doubt still largely practised, but orthodox practice was apparently regulated by the priests.

In Greek literature the earliest allusion to the healing art is found in Homer, who represents it as derived from the gods, indeed, but in the hands, not of priests, but of warriors, and to a certain extent of women. The only two doctors named in the Greek army are Machaon and Podalirius, who were also warriors, and led thirty ships to the siege of Troy. Their father, Esculapius, is represented as a chieftain to whom Chiron taught the healing art, as he did to Achilles. There is no allusion to temples open for the sick or to priestly medicine.

As might be expected from the nature of the subject the doctors are represented in the *Iliad* as exercising surgical functions. On occasion, indeed, all the warriors seemed to be capable of giving "first aid."

Dr. Leech here gave several quotations from Homer in illustration of these points.

According to the traditions concerning early Greek life it would seem as if those who first practised the healing art in Greece on the surgical side at least, were not connected with the priesthood, and there is no indication that medicine was then in the hands of a separate class. Later on, indeed, though when we know not, the chieftain versed in medicine of Homeric times was deified. Temples were erected to Esculapius in many parts, and thither patients flocked to them for cure. But, as far as is known, treatment employed here was almost entirely connected with the supernatural. However, it is quite certain that contemporary with the theurgic medicine of the temples of Esculapius, there was amongst the Greeks from earliest times a practice of medicine different from it, and not in priestly hands, and that in Greece, as well as in Egypt, two kinds of medicinal treatment were in vogue at the same time, one consisting chiefly of spells, charms, and other supernatural means, another in which natural remedies were for the most part given, though drugs originating in superstition were also doubtless at times used.

How early a distinct medical class was developed out of the primitive system of medical practice which the Homeric poems delineate is not known. Pythagoras (580-510), and other philosophers mixed up a little practical medicine with their speculative doctrines. At the end of the sixth century we hear of a famous Greek physician, Democedes, curing the King of Persia when the Egyptian physicians failed, and in the fifth a Greek, Ktesias, was physician to the Persian Court, and Hippocrates wrote his famous works.

It is impossible, under these circumstances, to suppose that Greek physicians did not exist till five centuries B.C. Indeed, we have much earlier allusions to them, though none are named. Moreover, the fulness of knowledge of drugs and disease from which Hippocrates wrote could not have been derived from his own experience. How far he obtained this information from the knowledge accumulated by previous physicians, or how much he owes to Egyptian medical lore, is not known. Hippocrates himself never speaks of Egyptian medicine, nor does he, though said to be connected with the priests of the Asclepian of Cos, allude to priests or their teaching, and he attributes, as I have said, the origin of medicine, not to the priesthood, but to a natural cause, the different influence of food in health and disease. There is reason to believe, therefore, that in Greece, long before the time of Hippocrates, medical treatment unconnected with the temples and priests had been cultivated; that starting from a time when the chief of a tribe or a family practised medicine, a class of physicians had gradually developed.

Of those who in earliest times exercised the healing art in Assyria, Babylonia, Phœnicia, India, and China we know nothing. This defect in information, however, with regard to these countries is of the less importance, since we must look upon the Greeks, and perhaps the Egyptians, as our medical forefathers. From them alone has medical knowledge come down to us.

How far in prehistoric times the medical practice of Egypt and Greece resembled that now met with amongst uncivilised people it is of course impossible to say. In almost all, if not in all, countries there are practitioners of medicine. Statements with regard to the absence of medicine men and the use of drugs in wild tribes must be accepted with reserve unless the reporter has lived with them. In the Andaman Islands there seems hardly any indication of a medical class, and often medical treatment is undertaken by some member of the household. Amongst the old Peruvians, too, the old women acted, at least in the case of the common people, as their medical attendants, and in South Australia, in smaller ailments at least, each one is his own doctor, but these are exceptions. Almost everywhere we find medicine men. Sometimes, as in New Guinea, they are hardly differentiated from the other people. In most tribes, however, they form a distinct class, and often they hold a high position, as amongst the Dakota Indians, the aboriginal tribes in Victoria, and in Samoa.

In rude tribes, as in Egypt and in Greece, there is evidence that at times two kinds of medical treatment co-exist. In Schoolcraft's work on the North American Indians it is pointed out that besides those who treat by magic and the invocation of spirits there is a class of medicine men not to be confounded with them who treat disease by natural remedies, using emollient applications externally and drugs internally. From what we can learn of the past and what we can observe among uncivilised peoples of the present day it seems probable that a knowledge of the influence of drugs on external or internal ailments has tended everywhere to accumulate in the hands of certain individuals; usually, perhaps, in those of the chief of the tribe, sometimes in those of his wife, but not infrequently other members become the special depositories of medical knowledge. Eventually differentiation of function occurred and a distinct medical class was formed. Doubtless this was a gradual process and was accomplished in many ways. At times it may be that the priesthood took part in it, but there is no evidence that this was always or even often the case.

The connection between medicine and the supernatural is easily explained. From the very first, ideas with regard to the action of drugs must have been combined with those concerning supernatural agencies, for spirits seem everywhere in man's primitive state to have been accepted to a greater or less extent as a cause of the phenomena of Nature, and being regarded as forces separate from the matter they influenced, they became soon looked upon as definite entities capable of producing good or evil apart from the material with which they were connected. Disease being due to an evil spirit, to cast it out was equivalent to curing the disease, and the means used to cast out spirits were by no means always ineffective in curing disease.

We know that at the present time many ailments are due not to tissue changes—at least, not to such as are capable of physical recognition—but to what, for want of a better name, we call neuroses. We know these neuroses are often little influenced by ordinary remedial agents; they may be removed by moral management. But we know, too, that they may often be cured by powerful impressions on the nervous system. This is especially well seen in hysterical paralyses of all kinds. The cures effected in nervous conditions by "faith healers" is well known. We cannot wonder, then, that in an early stage of society, when these conditions were perhaps even more common than at the present day, such treatment as would follow from belief in spirits and demons would have at times a curative effect and lead to a belief in its general efficacy; and this is the reason why everywhere we have two kinds of treatment used, one consisting of remedial agents having a physical effect, the other of agencies acting on the nervous system.

Real remedial agents, too, were often used with spells, or spells were employed to strengthen their effect. When the young men bound up the wound of Ulysses they

The blood stream red

Stanching with the singing of a potent spell.

In some uncivilised countries, as in Babylonia of old, the effect of drugs is largely attributed to spells associated with them.

The early and close connection of medicine with the priest-

hood and of doctors with priestly functions is readily accounted for without assuming that one is developed from the other. Religious functions, as Mr. Spencer points out, not infrequently centred in the heads of families and tribes, and when the priestly class was initiated it would naturally tend to assume to some extent the medical function.

It is well known that the power to deal with bodily ailments is a great advantage to those who minister to spiritual wants. Moreover, if the supernatural method of healing were in the domain of the priest, it would be only likely that he should also take upon himself the use of natural remedies, the more so because he would often have special opportunities of acquiring all the known information concerning natural remedies.

In process of time changes would occur, differing in various countries with the modifications in their religious and social life. In some, as in Egypt, the priesthood would absorb more and more of the medical functions and supernatural treatment would increasingly prevail. In others, as in Greece, the medical class would develop, and *qua* medicine, the sacerdotal element would lose ground. And there would be times, too, when medicine would be equally practised by priests and physicians.

As is well known, tradition in Egypt, Greece, and India gives a divine origin of medicine, and this has been pointed out as an indication of the origin of the medical profession in the priesthood. That it is in part due to an early connection there is no doubt. Medicine was a valuable addition to the social class that it should be represented as originating from the gods. It was with the priests, no doubt, that the tradition originated of the more than human origin of medicine.

In reviewing the progress of medicine Hippocrates stands out prominently as a landmark in our medical genealogy. In his writings we find an astounding progress in medical knowledge on anything which had previously been produced which has come down to us. We find, too, the lines correctly set forth on which medicine must be studied in order to advance, and rules of professional conduct which are an important feature in medical ethics of the present time.

Hippocrates, in the first place, absolutely denies the supernatural origin of disease. "No one disease," he says, "is either more divine or more human than another, and none arises without a natural cause." This was in direct opposition to all we know of priestly teaching. Throughout his works we find not the slightest indication of belief in popular superstitions; amulets, charms, etc., he never mentions. He shows a contempt for charlatanism. He advocates the exclusion of all purely speculative theories, yet he does not oppose the use of hypotheses, for he employs them himself. He teaches the necessity for careful observations of the natural history of disease, and the conduct of treatment in accordance with them. He points out the importance of knowing the nature and course of diseases, prognosis that is, in order to treat them properly. "He will manage the cure best," he says, "who has foreseen what is to happen in the present state of matters." It is to Hippocrates that we trace the system of casetaking, and he has recorded in a concise and clear manner the summaries of forty two clinical histories. In none of his works do we find any indication of self-laudation. He certainly did not select his successful cases for record, since more than one-half of these cases he reports died. In the oath which he or one of his successors drew up for candidates wishing to enter the medical profession, each had to swear by Apollo as follows: "With purity and with holiness I will pass my life and practise my art," and "Whatever in connection with my professional practice, or not in connection with it, I see or hear in the life of men which ought not to be spoken of abroad, I will not divulge, as reckoning that all such should be kept secret." He lays down as a general rule for the physician to do good, or at least no harm. He issues caution against exposing patients unduly during examination and operations, and suggests that it is better for a physician to go without his fee than to trouble a sick man for it.

The medical progress in the Hippocratic era was indeed immense. It would have been fortunate for mankind if it had continued on the lines laid down in the Hippocratic works. For many centuries after Hippocrates there was a

great activity in medical research and an enormous number of drugs were introduced. Dioscorides in the first century of the present era described 500 medicine-yielding plants, besides 90 earths and metals.

Theories as to disease and the action of drugs were continually brought forward, and though for the most part false, they were incentives to continued investigations. Much advance in knowledge was doubtless made, and if you read the Celsus who wrote on medicine and surgery in the latter part of the first century, you will be surprised to find how far advanced was the knowledge in certain parts of both of these subjects. But for several reasons the advance was not what it should have been considering the great industry displayed. Attention was almost wholly directed to finding out remedies for each ailment by simple observation, and little attempt was made to determine the cause of the ailment. Of theories concerning these causes there was an abundance, but of direct search for them there was little or none.

Physiology and pathology were non-existent. Then, again, very soon after the Hippocratic era superstition and the connection of disease with the supernatural began to thrive, and these do not initiate but are fatal to progress in the healing art.

As we ascend from Hippocrates to Galen, who lived in the second century, charms and amulets figure more largely in the remedies for disease; then, too, it would appear as if the physicians were more anxious to have their names connected with some new remedy or theory than really to add to knowledge. There was a great falling off from the high standard of the ethics of Hippocrates. With Galen we reach the high-water mark of progress of the Greek school. He added to real knowledge indeed, but his very pre-eminence was an evil, for he adopted a false theory with regard to causes and cure of disease, and his name was sufficient to secure its adoption in medicine for nearly 1,500 years. After Galen medicine rapidly deteriorated, superstition increased, and physicians seemed simply engaged in trying to tickle each ailment with a series of remedies. The horizon darkened, and in the Middle Ages medicine fell to a very low estate. Many causes contributed to this, but the most potent were the spread of superstition, and the ideas promulgated by many clerics that diseases were due to supernatural causes, for it followed that cures must also be of supernatural origin, and in the Middle Ages we find supernatural agencies largely relied on in treatment, whilst the knowledge concerning the use of natural remedies was far less than in the first century.

Dr. Leech concluded his address by pointing out some lessons to be derived from the history of our fathers. He advised his hearers above all things to cultivate exactness in observation, and to beware of accepting unproved observations, and of accepting hypotheses as facts. The art of healing could not advance far by simple observation of what did good in individual ailments. A knowledge of collateral subjects was requisite, and not until anatomy, physiology, chemistry, and pathology became subject to study could great progress be made. What is true in regard to the progress of medicine is also true in regard to the individual. A wider knowledge of the scientific collateral subjects—physics, chemistry, anatomy, physiology—will tend to make the student a better medical man, and will stand him in good stead in the practical work of his profession. For the advancement of medicine they are absolutely essential.

Finally, Dr. Leech reminded his audience of the teaching of Hippocrates with regard to conduct 400 years ago. It was considered essential that a medical man should pass his life in purity and holiness, that he should respect the confidence of his patients, and that he should be careful of their feelings; that he should be ever on his guard lest what he prescribed should do harm; that he should avoid all kinds of charlatanism. These and many other injunctions should press on those living in the nineteenth century even more strongly than on those who lived before the present era. We should never forget in this respect the teachings of the great Father of Medicine.

A Bill has been passed by the Massachusetts House of Representatives, making mandatory the establishment of a State hospital for tuberculous patients.

REVIEWS.

GUNSHOT INJURIES: THEIR HISTORY, FEATURES, AND TREATMENT. By Surgeon-General Sir T. LONGMORE C.B. Second Edition. London: Longmans, Green, and Co. 1895. (Royal 8vo, pp. 880. 31s. 6d.)

ALTHOUGH this is nominally a second edition, it is so entirely rewritten and rewritten as to be practically a new book. Sir T. LONGMORE has long been known not only as a high authority on all that pertains to gunshot injuries, and the duties of the military surgeon both in the field and in the hospital, but as a writer of power and grace. The work before us fully comes up to his high standard, and it is a matter for congratulation to be able to point to this veteran of the professions of arms and of surgery, who is not only writing, but able to spend so much labour on a fit presentation of his matured views upon a subject which has acquired a large amount of interest during recent years.

When we recall the fact that it is some seventeen years since the first edition of the book appeared, and that during this period most remarkable changes have been carried out in the firearms and projectiles of all the leading armies of the world, it is not surprising to find that the subject-matter has necessitated material alterations. The earlier pages are devoted to a consideration of the means by which gunshot injuries are produced. This portion of the work is quite up to date, and is followed by chapters dealing with the causes which influence the nature, characters, progress, and ultimate issues of these injuries. The characteristic features, primary symptoms, and complications of gunshot wounds are also fully considered; in this section a reluctance is noticeable on the part of the author to accept a specific micro-organism as the essential parent in the production of tetanus among those wounded on a battlefield. The ulterior consequences and general treatment of gunshot injuries in field practice are systematically discussed, though perhaps the student may think somewhat inadequately so. The chapters upon the administrative arrangements for the care and treatment of wounded soldiers in time of war are excellent. The statement of statistical facts is good so far as it goes, but loses much of its value from being based mainly upon returns relating to the Crimean war, the United States war of the rebellion, the Franco-Italian and Prusso-Danish wars, and the great war of 1870.

For a standard work of this kind it is regrettable that the author has not been able to gain access to reliable statistical facts, if such are available, regarding our more recent expeditions, such as those in Egypt, Burma, Chin Lushai, Hazara, and Waziristan, in which weapons of greater range and velocity were employed. There would have been of incalculable value, and their omission constitutes a defect in what is otherwise a good book.

On the whole this new issue of Sir T. Longmore's standard work fully maintains its character as a worthy representative of British military surgery. The book is one which we strongly recommend to the notice, not only of naval and military surgeons, but also of those engaged in civil work, since it contains a succinct account of our present knowledge of facts and of questions in regard to gunshot injuries, available in no other form. The book is printed in excellent type and well illustrated.

A GERMAN-ENGLISH MEDICAL THESAURUS, ETC., AND GERMAN AND ENGLISH INDEXES FOR PHYSICIANS AND MEDICAL STUDENTS. By Rev. HENRY LOSCH, M.D. Philadelphia, Pa.: Published by the Author. 1895. (Cr. 8vo, pp. 323. 2 dols. 50 c.)

THAT some knowledge of German is a very great advantage in these days to any medical man, and almost essential to one who desires to keep abreast of any special study or department of medicine or physiology will not be denied. We are disposed, therefore, to welcome any work which professes to smooth the path of the student. The plan of this work is somewhat cumbersome, though it is true that a learner who worked conscientiously through Dr. Losch's pages will have gained a very copious vocabulary. The plan is to take in

succession the German words connecting various parts and organs of the body and then to enumerate the derivative and qualifying words in use.

The chief defect in this portion of the work is a certain degree of redundancy, especially in the direction of the retention of words which are practically obsolete so far as modern medical writers in the German language are concerned. On the other hand, some words in common use are omitted. German-English and English-German indexes are appended. They form in fact a dictionary of the two languages, with the drawback that the reader is referred back to the word in the vocabulary, but with the advantage that when it is found he finds also a collection of related words and of synonyms. The volume contains also a table of the irregular verbs, and of the declensions, and also a series of short dialogues.

Dr. Losch states his reasons for the inclusions of these grammatical forms in the following sentence, which is worth quoting, also, because it will serve to make plain to the inexperienced why it is that the Englishman accustomed to short sentences and clear arrangement of ideas sometimes finds German writing so extremely difficult of comprehension. "The reason for making this addition arose from the conviction that if persons studying or having studied the German language, on the one hand, can classify a noun at sight by looking at the schedule of the terminations of each declension, inasmuch as there are four different classes of declensions in German, after which the nouns must be declined, wherefore every representative noun in this work has attached the number of the respective class of declension to which it belongs; and, on the other hand, such persons also know the irregular verbs, and can readily refer by looking at the schedules of conjugations of these verbs, to the various changes they undergo in the process of conjugation in the various tenses, etc., they certainly have overcome two of the foremost difficulties in the study of this language." The sentence will serve to prove that still another difficulty will remain.

Dr. Losch does not mince matters with his pupils, for the very first word in his vocabulary is *Brustschlüsselstein zitronenfärbte muskelschwind*, perhaps as appalling a specimen of a compound word as man could desire. However, Dr. Losch did not invent the German language, and cannot justly be blamed if some of its products are a little clumsy. His English is sometimes at fault, as where, for instance, he makes a patient ask: "May I eat something, or must I remain jejune on an empty stomach?" The phrases are meant to be alternatives, but either would be apt to raise an antipathy smile on the face of an English physician. Had the book been revised by an Englishman having some acquaintance with German it might have been much improved in other respects also; but, on the whole, we can recommend it as a means of becoming familiar with something of the spirit of the language, and more particularly with the mode in which compound words are formed.

CAMBRIDGE NATURAL SCIENCE MANUALS: THE ELEMENTS OF BOTANY. By FRANCIS DARWIN, F.R.S., etc. Cambridge: University Press. 1895. (Cr. 8vo, pp. 235, 94 illustrations. 6s.)

This is a very useful little book for the beginner, being very plainly and intelligibly written. The author commences with a brief account of yeast (ascomycetes), describing its unicellular structure, reproduction, nutrition, and the resultant fermentation. He also describes the composition of Pasteur's solution for the artificial culture of the yeast plant and the determination of its constituents. He then proceeds to the more complex spirogyra, dwelling particularly on its nutrition, especially in relation to that of yeast, and the assimilation of carbon. This chapter finishes with a few further particulars of the vegetable cell, illustrated by examples from the root of maize, the hairs of *Indeum*, and the cortex of *Ranunculus*. One defect we find in this and succeeding chapters is the absence of dimensions or approximate and comparative size of the different organisms under discussion. The figure of yeast represents it under a "high power"; the figure of spirogyra shows a single cell, enlarged to about two inches in length and three-quarters of

an inch in diameter, without any indication whatever of size.

The second chapter treats of the seeds of the bean and pumpkin and of tubers and bulbs with reference to germination, vegetation, and growth, the production and storage of "reserve material," and its subsequent utilization. In this chapter some of the figures are of natural size and some are reduced—a fact which the student is left to discover for himself. Generally speaking, the figures are intelligible and afford a good idea of what they are intended to represent, but there are some exceptions, that, for instance, on page 64 intended to show collenchyma in the stem of a Clematis. Apart from these defects, however, this is one of the best little books on rudimentary botany. Each of the fourteen chapters contains a mass of information presented in the simplest language, with a good selection of examples to illustrate the various facts and phenomena. Why the bean flower, which is so easily obtained, should be replaced by the sweet pea (p. 148), is difficult to understand, though one is just as good as the other to illustrate the papilionaceous type. Only, why not have at once taken the sweet pea as the type? Following the introduction to botany are some thirty pages of instruction in practical work on the types described. We note the old error (p. 223) in describing the seed vessel of the shepherd's purse (*capsella*), where the replum is confused with the septum. "Numerous ovules are found supported on a flattened central dividing wall—the replum." The ovules are borne on the replum, or frame, not on the septum or partition.

FORMULAIRE DES SPÉCIALITÉS PHARMACEUTIQUES. PAR DR. M. GAUTIER et F. RENAULT. Paris: J. B. Baillière et Fils. 1895. (Fcap. 8vo; pp. 300. Fr. 3.)

This pamphlet is intended to give information in regard to French pharmaceutical specialties, of which it is stated there are 1,500 at present laying claim to the favour of French physicians. In the first part the different specialties are described—their dose, use, and composition, but the information in regard to the latter is frequently conspicuous by its absence, although this would have been of the greatest service to the prescribers. For example, under *Cigares de Joy*, *Cigarettes Espie*, *Mac de Suez*, etc., no hint is even given of their composition. Again, the work in parts is carelessly done—lanoline *Lieberich* is given as a synonym for vaseline, and in the index, or *Mémorial Thérapeutique*, lanoline is stated to be a specialty of Kénor.

The second part contains a Therapeutic Index, or *Mémorial Thérapeutique*, in which the specialties are allotted to an alphabetical list of diseases. In the third part or *Mémorial Pharmaceutique*, the makers' names are affixed to an index of the specialties, and finally there is a similar list of *specialistes* or manufacturers of specialties.

In the preface M. le Sénateur Cornil explains some of the defects in the French law in regard to the practice of pharmacy and the sale of specialties, showing that in many cases a trade mark confers more protection to a manufacturer than a patent, that it does this without possessing merit, and often not in the interests of public health. There is much information given in regard to French specialties in this little work, which it would require a wide search to obtain elsewhere.

A TEXTBOOK OF PHYSIOLOGY. By M. FOSTER, M.D., F.R.S., Professor of Physiology in the University of Cambridge. Sixth Edition. Part II. The Tissues of Chemical Action with their respective Mechanisms. Nutrition. London: Macmillan and Co. 1895. (Demy 8vo, pp. 379 to 917. 33 illustrations. 10s. 6d.)

This part of Professor Foster's well-known textbook treats of secretion, digestion, absorption, respiration, the elimination of waste products, and general metabolism. It is very little different from Part II of the fifth edition. The rapid appearance of successive editions indicates that Foster's *Physiology* continues to hold its own against numerous competitors. We note that a separate index has been added to this part; this will prove a most valuable and useful addition.

A MANUAL OF BOTANY. By J. RAYNOLDS GREEN, F.R.S., etc. Vol. I, Morphology and Anatomy. London: J. and A. Churchill. 1895. (Crown 8vo, pp. 398. 7s. 6d.)

This is another of the very few reliable guides to botany offered to students, for, although the author was at the outset considerably hampered by conditions, it is evident that he possesses a thorough knowledge of his subject, and that he has conscientiously performed his task, in spite of the difficulties under which he started. Professor GREEN, it will be remembered by many, succeeds Professor Bentley as Professor of Botany to the Pharmaceutical Society, and it was at first intended that the present work should appear as the sixth edition of Bentley's *Manual of Botany*, but the death of Professor Bentley gave the author more freedom. This he has wisely exercised, yet the result is not quite so satisfactory as it might have been had Professor Green been free from the beginning. The fundamental alteration is the separation of the anatomy of plants from the morphology, the former having been practically rewritten and illustrated by numerous new figures, some original and some borrowed from the best sources. So far as general morphology is concerned, the old figures serve very well, and compare favourably with those of most books of the kind. Those who have used the ponderous predecessor, in which nearly the whole range of botany is taught in one volume, will realise the convenience of dividing it into two parts; and it is to be hoped that the second part, dealing with the classification and the physiology of plants, will speedily follow. Preferably we would have divided the matter differently, associating morphology and classification in one volume, and anatomy and physiology in the other; and we offer the author this suggestion for adoption in future editions.

If there is one thing we would find fault with, it is the retention of a large number of practically obsolete designations of different modifications of the fruit or seed vessel and of other organs. These names or terms are rarely, if ever, used in descriptive works, or heard outside the class room. The great objection to most of them is that they are only of very limited application, and that to apply such a system of nomenclature consistently would involve the invention of scores of other equally uncalled-for terms. On this point we do not agree with Professor Green in classifying the raspberry and blackberry with the "spurious fruits," because the fleshy edible part is absolutely the substance enclosing the seeds, or the true pericarp. We note, too, that the septum of the cruciferous fruit is confused with the replum. In the description of the roots of epiphytes (p. 23) there is a distinct contradiction, the erroneous part being that "they must draw their food entirely from the air in which they are developed." But errors of this sort are almost inevitable, and we point them out to give more strength to our recommendation of the book.

THE TREATMENT AND EDUCATION OF MENTALLY FEEBLE CHILDREN. By FLETCHER BRACH, M.B., F.R.C.P. London: J. and A. Churchill. 1895. (Demy 8vo, pp. 32. 1s. 6d.)

The author gives a summary of an extended experience in the treatment and training of children more or less imbecile, as well as of those with lesser degrees of defect, now termed "children mentally feeble." In his description of their physical condition the author dwells upon the imperfect impressions received by the brain through the senses, and points out that music is always pleasing to these children. Therapeutic means and methods of training in movements and co-ordinated action are explained in very practical form with description of useful details. Conditions of body and brain, which in the aggregate render the child imbecile, are often met with singly in dull or backward children, and the hints given will be found of use in such cases. Children feeble in brain power have usually but feeble power of resisting disease, and should be carefully protected against the dangers of phthisis and inflammatory affections; the teeth, throat, eyes often require attention. Hygiene, diet, and special exercises to cause co-ordinated movements, improve gait, speech, and impart good social habits, need intelligent and persistent care; by such means the child may be edu-

cated up to occupy a position more self-helpful, and less dependent and degraded than when left untreated and untrained.

We heartily agree with Dr. BRACH that it is nothing but a popular fallacy to suppose that such children will improve of themselves as they reach the age of fuller development. Amelioration can only be afforded by early, patient, and prolonged training adapted to the special needs of the individual child. We recommend the perusal of this practical work to all who are concerned with the care and training of children of deficient mental power.

THE USE OF SHORTHAND BY THE STUDENT: WITH EXAMPLES. Issued by the Society of Medical Phonographers. London: Sir I. Pitman and Sons. 1895. (Fcap. 8vo, pp. 32. 8d., by post 8½d.)

This publication deals with the whole subject of note-taking by the student. In the lecture room verbatim notes are not recommended, but the student is advised to take a full summary, using only the right-hand pages of his notebook. The left-hand pages are to be left blank for the record of supplementary facts which he may observe in his daily work or meet with in his reading. In this manner the student compiles a miniature treatise of his own. The ease with which this may be done by the help of shorthand, the mental training it affords, and the incentive to original work it supplies are pointed out, whilst the contention that shorthand thus used prepares a man to excel in the examination room and the sphere of his life's work is self-evident. The writer shows how the student may most profitably use shorthand at the bedside, in the laboratory, in the wards with the physician or surgeon, in the out-patient room, and in his reading. Examples of actual notes are given, and the best form of notebook as well as the most useful pens are mentioned. Every student, and all whose duty it is to observe facts or make notes of what they read, see, and hear, should read this practical little work.

HYGIENE AND PUBLIC HEALTH. By LOUIS C. PARKES, M.D., D.P.H. London: H. K. Lewis, 1895. (Crown 8vo, pp. 550, 60 illustrations. 10s. 6d.)

Dr. LOUIS PARKES' handbook has deservedly reached a fourth edition, which fully maintains the standard of excellence to which its popularity is due. It is clear and practical throughout, leaving nothing obscure, and evading no difficulties. In matters still *sub judice* Dr. Parkes gives his readers the benefit of the divergent views of different authorities. The work has been carefully brought up to date, and unless we are mistaken the additions include more than one new illustration. Sanitary law is not touched upon, and there is much to be said in favour of the omission. It would be difficult even for Dr. Parkes to make a legal chapter interesting, and it is questionable whether the study of the original Acts is not more profitable than that of any summary of them. As in former editions, the type is good and clear, and there is a sufficient index.

MEDICAL PARTNERSHIPS, TRANSFERS, AND ASSISTANTSHIPS. By W. BARNARD, M.A., LL.B., and G. B. STOCKER. London: Stevens and Sons. 1895. (Demy 8vo, pp. 260. 10s. 6d.)

The publication of this volume will have rendered a most valuable service to medical men if it should teach them the necessity for obtaining competent advice before entering into partnerships. No merchant or manufacturer thinks of taking such a step without submitting the conditions of his partnership agreement to his legal adviser. The medical man, with far less knowledge of the world than the merchant or manufacturer, too frequently risks his future on a sheet of notepaper drawn up by himself or his intending partner.

The inquiries of correspondents published in our columns testify to the troubles and losses which are the natural consequence of such rashness. The general law of partnerships—one of the most difficult branches of the law—necessarily governs medical partnership, and a considerable portion,

therefore, of this volume deals with what is common to all partnerships.

The matters of special interest to the medical man are to be found in the chapters relating to Restrictive Covenants, Introduction to Patients, and Assistants, and in the general advice, founded on long experience of the subject, given by Mr. STOCKER in Part I. Forms of deeds and agreements are, like printed forms of wills, edged tools to play with, and the use of them without legal advice will probably illustrate the old adage that "the man who is his own lawyer has a fool for his client." At the same time they serve the purpose of guiding the medical man in ascertaining what are reasonable and proper provisions to be introduced into a partnership agreement.

The chapters on Restrictive Covenants, Introductions to Patients, and Assistants, should be read carefully. They have all been subjects of frequent litigation arising from the ignorance of medical men as to the law which regulates them. For instance, we have known practitioners of some standing surprised to learn that the general hiring of an assistant is in law presumed to be for a whole year, and who have suffered for their ignorance. Or, again, we have listened to a costly lawsuit between two men as to the effect of a restrictive covenant against practising within a given radius, which a properly drawn clause in the partnership deed would have entirely obviated.

The general practitioner finds it difficult, often in fact impossible, to start alone. A partnership is, therefore, a necessity to him, and he forms it when comparatively young and inexperienced. Too often may he be said to do it in haste and repent it at leisure. If he will read Messrs. BARNARD and STOCKER's volume he may avoid some of the pitfalls into which he will otherwise tumble; but he will, in our opinion, read it with still greater profit to himself if he is thereby induced to get the best possible advice before he commits himself to any partnership.

SURGERY, ITS THEORY AND PRACTICE. By WILLIAM JOHNSTON WALSHAM, F.R.C.S., M.B., C.M., Senior Assistant Surgeon, Lecturer on Anatomy, and Surgeon in Charge of the Orthopædic Department, St. Bartholomew's Hospital, etc. Fifth Edition. London: J. and A. Churchill. 1895. (Cr. 8vo, pp. 796, 380 illustrations. 12s. 6d.)

Born teachers and students will welcome this very useful manual of surgery in a new and improved form. The value and popularity of Mr. WALSHAM's book are well attested by the facts that this is the fifth edition, and that 20,000 copies have been printed in less than eight years. This, though a much improved edition, has not been materially enlarged. Many subjects have been compressed, and many diseases and operations not previously mentioned are now described, but at the same time useless and obsolete matter has been expunged. Attention has been paid to the subject of bacteriology, the pathological sections have been carefully revised, and the chapters on surgical treatment, as those on injuries of the head and abdomen for instance, brought into full accord with modern teaching and practice.

PRACTICAL SANITATION. By GEORGE REID, M.D., D.P.H., medical officer to the Staffordshire County Council. Third Edition. London: Charles Griffin and Co. 1895. (Crown 8vo, pp. 350, 100 illustrations. Price 6s. 6d.)

The third edition of Dr. REID's very useful little manual differs from its predecessors chiefly in being brought up to the present date. It abounds in practical detail, much of it of a kind not to be found in textbooks, written more especially for professional readers, and may safely be recommended to medical officers of health who desire to be kept posted in the latest improvements in sanitary appliances. Dr. Manley's Appendix, dealing with Sanitary Law, is also brought abreast of the times. The whole work bears traces of careful revision, and the only overblownness which we have succeeded in discovering are of a purely trivial character.

NOTES ON BOOKS.

Edinburgh Hospital Reports. Edited by G. A. Gimson, M.D., D.Sc.; C. W. CATHCART, M.A., M.B.; JOHN THOMSON, M.D.; and D. BERRY HART, M.D. Volume III. (Edinburgh and London: Young J. Pentland. 1895. 8vo, pp. 762.)—The third volume of these Reports, which are published under the supervision of the Editorial Committee of the Royal Infirmary, the Royal Hospital for Sick Children, and the Royal Maternity and Simpson Memorial Hospital, contains a very long list of papers by members of the medical and surgical staffs of these hospitals as well as by others. We cannot pretend to do more here than notice the appearance of the volume, but we hope to publish abstracts of some of the papers, which appear to have the greatest clinical value, in the EPIGRAMS. The editors are to be congratulated on the way their task has been fulfilled. Appended to the volume, but with a separate pagination, are the annual statistical tables of the Royal Infirmary and the Hospital for Sick Children.

The Conditions of Radical Cure in Cancer, and other Reprinted Papers. By HERBERT SNOW, M.D. Lond., etc., Surgeon to the Cancer Hospital, London. (London: J. and A. Churchill. 1895. Cr. 8vo, pp. 63. 2s. 6d.)—This collection of reprinted papers deals with certain points of interest relating to the treatment and pathology of malignant disease. In the first and second of these reprints the author discusses questions of treatment, setting forth in the former the principles by which the operating surgeon should be guided in combating the different forms of cancer, and in the second pointing out morbid conditions indicative rather of expectant than of active surgical treatment. The third paper directs attention to the principles involved in the view that there is no absolute line of demarcation between malignant and non-malignant growths. The fourth and last paper is a pithy review of the author's conclusions with regard to the most recent investigations on the pathology of cancer. These papers are suggestive, and though not free here and there from disputable assertions, prove that the author has taken full advantage of the abundant clinical material at his disposal and studied very carefully the latest views relating both to the nature and treatment of cancer.

Alcoholic Drinks. By Dr. LISBOA PINTO. (Colombo: Times of Ceylon Office. 1895. Small 8vo, pp. 65.)—This clearly printed and well arranged pamphlet is in the form of a catechism, the information being presented in the answer to each separate question. The subject matter is Alcoholic Drinks; with Notes on the Medical, Social, Political, and Religious Aspects of the Liquor Question. With the medical part alone we have to do, and we can commend the lucid exposition of the leading physiological and pathological relations of alcohol as eminently calculated to popularise knowledge which would be of inestimable value to all persons who have at heart the promotion of sobriety. This useful and interesting little volume by a Ceylon member of the British Medical Association is only the latest of a long series of instructive publications on a subject of deep interest by members of the profession, in the truest interests of individual and public health.

PRESENTATION.—The Mayor of Norwich, Sir Peter Eade, was presented on September 25th with his portrait, painted by Mr. Forbes, R.A., in recognition of services rendered by him in connection with the organisation of the Norwich Castle Museum. The presentation was made by Lord Walsingham on behalf of the subscribers. The Norwich Town Council also presented the honorary freedom of the City to Sir Peter Eade.

MEDICAL MEN AND POLITICS IN PORTUGAL.—The *Official Journal* of Portugal recently published a scheme of reform of the law relating to political elections. The number of deputies is fixed at 150. The number of public officials with seats in the legislative chamber must not exceed 40 at any given time. In the same way the number of barristers and doctors who can sit is limited to 20 representatives of each profession.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

POCKET COCAINE SPRAY.

Messrs. BURROUGHS, WELLSOMER, AND CO. have submitted to us a pocket cocaine spray, which has been designed and introduced with a view to obviate the toxic effects so frequently produced by the indiscriminate use of cocaine solutions. With larger instruments holding a considerable quantity of the solution, sufficient for many doses, it is difficult to prevent excessive use of it. By means of this little spray the patient is enabled to control the quantity with the greatest possible nicety, since he cannot exceed the dose ordered by the physician, the solution being prepared from the "tabloids," one or more as the case may be. It not only secures accuracy of dosage, but it enables the patient to carry on the treatment systematically and regularly, as the spray itself can easily be carried in the waistcoat pocket. The value of cocaine in the earlier stages of hay fever, coryza, and inflamed and congested conditions of the nasal mucous surfaces generally, is generally recognised.

MALT PREPARATIONS.

SAMPLES of various malt preparations have been submitted to us for examination by the Trommer Extract of Malt Company, Fremont, U.S.A. The extract of malt is claimed to be a non-fermentable diastase nutrient, and to be much more desirable in prescriptions than a syrup or elixir. That the use of malt extract as an aid to digestion has not attained the result desired may no doubt in many cases be ascribed to the inferior diastase power of the extract employed, as many samples of malt extract are to be met with that are very poor in this respect. Analysis of a sample of Trommer's malt extract shows it to be a preparation of good quality, having diastase power equal to the conversion of its own weight of starch in thirty minutes. It is of pale amber colour and good consistency. The extract of malt and cod-liver oil is as palatable as can be expected of such a preparation, containing about 40 per cent. of cod-liver oil. It is not an emulsion or so-called solution, as the oil globules are readily discernible under the microscope.

In another preparation malt extract has been utilised as a means of masking the bitterness of cascara sagrada; it contains in 4 fluid drachms the active properties of 15 grains of cascara. The London agents of these preparations are Messrs. F. Newbery and Sons, King Edward Street, E.C.

A NEW MOTOR FOR SEWING MACHINES.

THE British hygienic motor is a new arrangement for driving sewing machines, which has been devised by Mr. N. A. Amberton and is sold by the British Hygienic Motor Company, Limited (120, Tottenham Court Road). It is designed to lighten the labour required and to avoid the peculiar movement involved by the use of the ordinary treadle—a movement which has often been objected to as being injurious to women when continued for any length of time.

The arrangement is exceedingly simple. Instead of the motion being derived from a rocking bar lying under the treadles it springs from a similar rocking bar lying close under the table, set in action by a sort of pendulum, which descends from it and terminates in a stirrup or foot-piece on which the foot rests. The worker's knee, when in proper position, lies under the rocking bar, and the leg is parallel to the pendulum. No downward pressure is applied; the mere swinging of the leg to and fro produces an oscillation of the rocking bar which, by a simple crank and connecting rod arrangement, is converted into circular motion and made to actuate the machine. A point of some importance is that, by means of a spring, the pendulum which carries the foot-piece is always brought to rest in such a position as to be clear of the "dead point" on the crank.

In estimating how far the new action is likely to be an advantage to the worker, one must consider the two main

claims which are made in its favour, namely, the saving of labour, and the hygienic advantages arising from its use. The fact that the machine will only stand at rest at every fourth stitch is a matter for the practical machinist, not for us. At first sight it might appear improbable that a mere variation of the mode of application of the force would make any material difference in the amount of force required; but a careful consideration of the muscular actions involved shows that besides the alternate contractions of the flexors and extensors of the ankle, by which alone the ordinary treadle is operated, the muscles of the thigh are also put in action so as to keep the foot applied to the treadle, and that this latter muscular activity is waste force so far as the movement of the machine is concerned, while with the new movement the flexors and extensors of the thigh alone are brought into action, and whatever energy they develop is expended entirely on the machine. We are, therefore, of opinion that there is a distinct saving of muscular effort in using the new movement.

Whether, however, the effort is judiciously distributed is another matter. With the old treadle both legs are used, while with the new arrangement only one is used at a time, and practically it seems likely that the right leg alone will be employed in driving the machine. This is certainly a drawback. Anything like unsymmetrical development of muscles is a thing one would avoid if possible, especially where, as in this case, the muscles called into action are comparatively few.

On the other hand, there are undoubtedly certain hygienic advantages in this new invention. In the use of the ordinary treadle there is always a certain amount of alternate flexion and extension of the thighs upon the trunk, a movement to which many evil consequences have, rightly or wrongly, been attributed: and although when the feet are properly placed this movement is reduced to a minimum, the constraint of maintaining them in this position is considerable, and there is very little doubt that in practice the ordinary treadle does often produce this movement to a considerable extent. In the new arrangement also it is possible to produce the same effect, but it is by no means necessary to do so, and when the knee is in the proper position it is certain that there is practically no movement of the thigh upon the trunk. In our opinion an even greater advantage of the new machine is that in its use the thighs are kept apart, and that considerable variation is possible in the position of the body. We consider, then, that the hygienic motor offers the advantage of lessened expenditure of effort, and a relief from some of the hygienic evils of the old treadle system, and that although the strain is all thrown upon a small number of muscles, these are among the strongest muscles of the body. The drawback seems to be the predominating activity of the one limb.

AUSTRALIAN WINE.

OPHIR WINE is an Australian wine produced from grapes grown in the Mount Ophir district, Victoria, which is in proximity to the site chosen by the Victorian Government for their experimental vineyard, and is said to be admirably suitable for wine growing. The soil there is highly ferruginous, and is said to produce grapes which yield a fruity wine containing iron. This Ophir wine is claimed to be ferruginous and to be prepared from pure grape juice and of natural strength. Analysis of a sample submitted to us shows it to be wine of a burgundy character, having a specific gravity of 992.4, and containing 14.75 per cent. alcohol by volume, 2.59 per cent. extractives, 0.38 per cent. acidity taken as tartaric acid, and 0.3 per cent. ash. The ash contains an appreciable amount of iron oxide, and thus substantiates the claim as to the ferruginous character of the wine. It seems to be a good sound wine. It can be obtained from Messrs. P. B. Burgoyne and Co., 6, Dowgate Hill, E.C.

CHLORIDE OF AMMONIUM PIPE INHALERS.

DR. J. STENSON HOOKER (Hastings) writes: Seeing a mention of a chloride of ammonium pipe inhaler in the JOURNAL of September 14th, I think it only fair to myself to state that Messrs. Burroughs, Wellcome, and Co. made such an instrument according to my design three or four years ago. My pipe inhaler, however, was of porcelain, but contained the two bowls and the sponge inside the cylinder just as described in the supposed new one.

NEW FEEDING BOTTLE.

Messrs. ALLEN AND HARBURY have submitted to us their new patent feeding bottles, which they claim to be an important improvement on the old-fashioned tube feeders, and free from the drawbacks of the ordinary boat-shaped bottle. The chief points are: (1) The ease with which the bottle can be cleansed, as shown in the appended illustration; (2) the

infant, in taking food, does not suck in air at the same time, thus removing one cause of wind, colic, and other infantile troubles. This is effected by means of a valve made of india-rubber, which is inserted like a cork and permits the air to go in, but does not allow the milk to exude in the least. It is graduated, so as to facilitate the mixing of milk or other food with any proportion of diluent required.

Further important advantages which this feeder has over others are the absence of the tube, in which milk often turned sour, leading to stomach disturbance; and the fact that the test, which is of ample proportions at the base, can be readily cleansed both inside and out.

A POCKET INSTRUMENT CASE.

MR. HENRY GREENWAY (Huddersfield) writes: In the BRITISH MEDICAL JOURNAL of September 14th, p. 621, is figured and described as a recently invented instrument case made by Messrs. S. W. & Co., and Thompson, for Dr. S. H. Appleford. The same kind made for me, under my instructions, a similar pocket case about twenty years since, I think, for carrying in the breast pocket of a coat, so that it would bend to the curve of the back when the coat was buttoned. The case, also, had a card loop in the centre of its upper edge, whereby it could be hung when in use to a button of the coat. I also had a removable enamelled leather cover for the case, to prevent perspiration or other moisture affecting the instruments. Some years afterwards another maker brought out a somewhat similar case, and I drew his attention, through the medium of the BRITISH MEDICAL JOURNAL, to my prior design.

THE GRACE TESTIMONIAL.

In addition to the amounts already acknowledged on behalf of this fund, we have received the following sums:

Donor	Amount	Donor	Amount
Dr. E. Mansel Symson (Liaison)	1	Dr. Cocking	1
Dr. Pearce (Diss)	2	Dr. Hall...	1
Fleet-Surgeon R. D. White (Gosport)	2	Dr. Addison	1
Per Mr. E. Cecil Montgomery, (Charity Cross Hospital)	1	H. Clapham	1

REPORTS

ON

THE NURSING AND ADMINISTRATION OF IRISH WORKHOUSES AND INFIRMARIES.

SPECIAL COMMISSION OF THE 'BRITISH MEDICAL JOURNAL.'

II.—SOUTH DUBLIN UNION.

THE union for the northern half of the city lies close to the Grangegorman Asylum, and near—rather too near—to the terminus of the Midland Great Western Railway. The workhouse is not so favourably situated as the sister union of the south, being in a more crowded part of the city: it is also smaller in area, though not so crowded. The nucleus of the building is the "Bedford Asylum," another of the Foundling Houses, to which has been added from time to time the various blocks that compose the North Dublin Union. This Board has adopted the wise plan of removing its children to schools in the country. We were sorry not to have had an opportunity of seeing them, as we understood that they are very satisfactory. The ground plan of the union is a double square, placed back to back; the connecting portion is the Bedford Asylum, the top floor of which is used as the Protestant Hospital, the lower floors being the female infirm wards. We had the advantage of the guidance of the master and matron, and we received every courtesy at their hands.

THE SICK.

as is usual in the Irish workhouses, are classified according to creed, the hospitals being duplicated and quite distinct. The Roman Catholics are nursed in two blocks, the male portion in a block near the gate, and the female in the buildings that form part of the square near the Protestant Hospital. The opposite side of the square is occupied in part by the male infirm. In both the male and female blocks for the Catholics the arrangement is the same; the staircase in the middle, the wards going off on each side for three storeys. The wards are oblong, having matting or linoleum down the middle; they contain about 36 beds each, tables and benches for those who are up, as there are no dayrooms. The windows, which are small and in heavy frames, face each other; the walls are brick surface painted, the upper walls having pitched roofs. The general appearance of the wards was good, clean, and neat, but they were too crowded, and in winter we were informed that more beds would have to be put in. Each bed had a locker table in which was kept the separate towel, and a bag with brush and comb was hanging at the foot of each bed. The fireplaces are the wide open grates, casting more heat than they give, and in some of the wards they had been smoking. We noticed some Tobin ventilators, many of which more often served as a wall. It is evident that the greater part of the ventilation is by means of the windows, the upper part of the frame falling inwards on a toothed bar. There are separate wards for children in each hospital. The bedding is hair or straw, on an iron bedstead, with pillows, with straw ticks for certain cases. The patients are classified as medical, surgical, and phthisical, and included all kinds of disease as in a general hospital.

THE PROTESTANT HOSPITAL.

for 191 patients is on the top floor of the old building; the male and female patients are on the one floor, also the children. The classification is the same as in the other hospital. The wards, 5 in all, hold, in the largest ward, 28 beds, and in the smallest, 23 beds. The quarters of the most nurses are in the middle, and the whole is self-contained. The wards are in style similar to those in the other blocks, but here also we noticed the difference in the work as done by the trained nurses and the nuns. These wards were not so crowded as those in the other blocks, but they were filled to their capacity.

THE NURSING

in the Roman Catholic Hospital is in the hands of the Sisters of S. Vincent de Paul, and we were pleased to notice that it

bore trace of being done in a business like way. It is evident that these nuns, from the variety of the works that they undertake, are well fitted for work in the workhouses, and if to this they would add hospital training as a qualification of the order, they would be invaluable for the work. They are assisted by a large number of inmates, as there are not nearly sufficient nuns for the wards. As far as we could see each sister had charge of a floor, or about 70 patients, and in the male block there were a large number of able-bodied men at work. One was dressing a case of extensive strumous ulceration of the neck, and another was in attendance on a patient recently admitted with delirium tremens. Everywhere we saw them acting as nurses. In the female block very many of the wardswomen are of indifferent character. During the night one trained nurse or a sister is up in each ward with pauper assistance. A trained head nurse is in charge of the Protestant Hospital, and she has 3 nurses working under her for 194 beds. Here also we found the pauper helps, 2 men and 2 women. There is a trained nurse for the night, with a male and female pauper to assist. The sick department is superintended by a resident medical officer, with two visiting doctors from the outside, who are salaried officers. Most of the cases for operation are sent to the general hospital, the surgeon in charge of these cases being of opinion that they stand a better chance of recovery under the more favourable circumstances in which they find themselves.

THE MATERNITY DEPARTMENT

consists of two wards, holding together 20 beds. There is no separate labour bed or ward, and the second ward is used for the waiting pregnant women. It has no separate offices. The women are attended to by a midwife. The nursery for sick children under the nuns is one ward, with a corridor as a playroom. There were no cribs, but only the small bedstead that looked unsuitable for the little things. The playroom was a bright, cheerful room, low chairs and tables, and some toys for the convalescents.

THE LUNATICS

are not at all well located in this union. The men are crowded into a small, dark, low-pitched dormitory, off which is a small dayroom, and their yard is an oblong concreted enclosure, with very high walls, in which are a few benches. In this we saw the men lounging about, with no occupation to relieve the tedium of their existence. The ward is furnished with "harrow" or box beds and the straw tick; a few benches were round the large old fireplace. Some of the men were here, and others in the equally dreary day room.

The females were lodged in equally unsuitable quarters. The greater part were in the yard at the time of our visit, and we were horrified to see amongst them a coffin lying on the ground, where it had been placed until the mortuary was unlocked; worse still, a low opening in the wall protected with wire netting permitted these unhappy creatures to see into the mortuary at all times. The yard was crowded with all kinds of idiots, some of whom were jabbering round the coffin. There is a paid officer for the male lunatics and another for the females; but these officers must be heavily handicapped by the miserable surroundings in any efforts they make for the good of their charges, who appeared to us to be in quarters better fitted for animals than for human beings.

THE MALE INFIRM WARDS

were another weak part of the establishment. We entered a dark low dormitory where we found 35 men congregated in a ward that would be full with 25 men in it. The windows are small and set high in the wall; the "harrow" beds and straw ticks give no idea of comfort; no armchairs or resting seats, benches forming a square round one of the old grates; the walls with rough surface, coloured, and the rafters uncoiled, completed a picture of neglect that was not creditable to the authorities. As a set-off against this dreariness, we found that the Master had turned a waste piece of ground into a nice garden for these old men; trees, shrubs, flowers, grass, and comfortable benches made a pleasant spot for them in the fine weather, and furnished some interest for them in the cultivation of their garden. There being no day-room for the infirm men, this formed a good outlet, but what must be their condition when winter keeps them indoors?

Their attendant is a wardman taken from the inmates, and they are locked up at night, depending on each other for such assistance as they may need.

THE FEMALE INFIRM WARDS

were not so crowded or so dreary. As before said, they are in the two lower floors of the middle block, there is more light, better-sized wards and more cleanliness; but these old women have no officer appointed to attend them, and they are under the charge of an inmate. Considering how nearly some of those we saw are to the stage of helpless infirmity, they can hardly be satisfactorily cared for by inmates, and certainly there is need of more supervision. Another part of the enclosure has been turned into a garden for the old women, where they can sit on comfortable benches and enjoy the sunshine and air. There is no dayroom for these wards.

THE SANITARY APPLIANCES

are placed indoors in the hospitals; they are placed either at the ends of the wards or in an annexe built out at the middle of the side wall of the ward. These consist of a watercloset flushed, a slop sink, and a bath with hot and cold supply. We observed that the closet pans were not properly cleansed, in some instances they were quite foul, and the baths were often the receptacle of various odds and ends, as though not in frequent use. In all the places that we saw off the wards there was no intercepting lobby; the convenience was too close to be sanitary, and one, at the end of a ward, appeared to be taken off the ward. The Roman Catholic hospitals have modern kitchens attached to them, where the whole of the food is cooked under the direction of the nuns. The Protestant hospital is served from the main kitchen. The main laundry is much too small for the work that it has to do. We were surprised to see that the Board had not yet adopted the many labour-saving appliances which help the work now that the able-bodied are so scarce in all the unions.

RECOMMENDATIONS.

We would most earnestly draw the attention of the Board to the question of nursing. We were struck by the large number of men employed among the sick—men who appeared to be capable of earning an independent living; how far is this system of pauper nursing responsible for keeping them in the house? We are most anxious to see these large city unions turned into training schools for workhouse nurses, but before this can be done the pauper nursing must be abolished. It demoralises the nurses and is responsible for the lower standard of nursing that is accepted in the workhouse hospitals. We would gladly see more nurses engaged and the places of the paupers taken by probationers, whose cost would certainly not exceed that of the paupers, and who would work more economically and efficiently. Another thing necessary is that all the hospitals should be worked by trained nurses in a business-like way like any other hospital. If these excellent nuns, who are doing such good work in the North Dublin Union, would obtain the necessary knowledge of sick nursing through some of the recognised schools, the value of their work would be enormously increased. It is too much the fashion to think that these hapless poor do not require skilled nursing, but their ailments are the same, whether in the hospital or the workhouse.

The condition of the aged and infirm cannot be regarded as satisfactory, either structurally or from the point of view of attendance. We would suggest that paid officers be appointed with quarters adjacent to the infirm ward. For the wards themselves, on the male side they should be condemned, and the inmates removed to more commodious and healthy surroundings. The same remark applies to the lunatics; we feel certain that more could be done in alleviation of their lot, with better quarters, opportunity of occupation or amusement, suited to their powers, and a means of outdoor exercise in more airy and cheerful grounds. The domestic offices might be improved by the introduction of more modern and suitable appliances, especially in the laundry, and we also suggest the erection of a small kitchen for the Protestant Hospital. The sanitary appliances of the maternity block should be taken into consideration, also those for the infirm and lunatic wards, for which department proper baths and

other conveniences are required. If the Board could only see its way to removing the sick to more commodious and healthy quarters, there would then be ample space for the better housing of the infirm and the lunatics.

MEDICAL MISSIONS.

DURING the meeting of the London Missionary Society's Centenary an afternoon was devoted to consideration of Medical Missions, of which it appears the Society has many.

Dr. S. H. HABERSHON, who presided, declared that it was peculiarly fitting that an afternoon should be devoted to the subject, for some of the earliest pioneers in medical missions were members of the London Society. In 1807 Dr. Morrison virtually commenced such work in China, and they welcomed Dr. Lockhart's presence among them then, who was now the oldest living medical missionary. Dr. Habershon went on to describe what doctors themselves were doing at home to help some of their fellows who had gone out, and described some assistance rendered by St. Bartholomew's Hospital Mission. Medical missions, he contended, had often opened the hard and prejudiced heart to the teaching of the missionaries. This was a point frequently insisted upon during the afternoon.

The first paper by Dr. J. C. THOMSON, M.A., of Hong Kong, gave a comprehensive view, with some details and statistics of the medical mission work now being done by the Society, not only in China, but in other parts of its spheres of labour. There were, he said, four chief forms of medical mission work—medical, evangelistic itineration, dispensing practice, hospital treatment, including the care of lepers in asylums, and the training of native workers. The most important and permanent results were obtained among in-patients in the hospital wards, while they were able to greatly relieve the condition of the lepers in the asylums. In India the Society had four great centres; one, at Noyoor, had 15 dispensaries in the neighbourhood. Out-patients, it appears, are treated in many thousands; but one centre was still without a hospital through lack of funds. China was probably the most important sphere for medical missions, for there was an absolute lack of any other provision for the rational treatment of physical ailments, and such treatment afforded a ready access to the hearts and homes of the people. The Society had two well-equipped hospitals at Hong Kong, also medical missions at Amoy, Shanghai, Nanchow, Wuchang, Kian Kian, Peking, and other places. Medical mission work was also carried on in Madagascar, Central Africa, and the South Seas. In conclusion, Dr. Thomson urged they should aim at an elementary medical education for every missionary occupying an isolated position, especially in the southern missions; a medical mission should also be regarded as an integral part of the equipment of every station unless local reasons rendered it unnecessary.

Dr. Fells, of Noyoor, Travancore, argued that the place given to medical work in the mission scheme by Christ was of the utmost prominence. But for years a medical missionary was a rare curiosity; and though the number had been increased of late, they were still a small band compared with those engaged in other branches of the mission scheme. He created some amusement by quoting the case of a high caste apothecary who was accustomed to make the necessary inquiries of his low caste patients and to examine their tongues still standing some yards distant. Dr. Fells also argued that medical mission work could not be called expensive, for in 1894 the South Travancore Medical Mission treated 42,320 patients at an average cost of 2½d. per head, including salaries of native agents and medicines, etc.

Other speakers included Dr. DAVIES, of Samoa, who had been simply an "ordained missionary" until he became convinced of the great need for the medical work; he had known a Samoan walk 80 miles on a rough road for medicine for a sick man, and he believed medical missions gave a most practical exposition of Christianity.

Dr. LOCKHART, who had first gone out to China in 1838, and received a most cordial welcome, gave his testimony strongly in favour of the work; and Miss BENHAM, from Amoy, declared that the sphere for medical women in China was unlimited; moreover, she would have every woman who went out have a little medical knowledge.

Mr. W. H. CAMPBELL, from South India, expressed a similar opinion, enlarging it to include men also. He would have some medical training given to every missionary, especially if he or she was to occupy an isolated position. Referring to the need of a hospital at the centre, where his brother (Dr. T. V. Campbell) had been stationed four years without one, Mr. Campbell said that the natives themselves were beginning to subscribe towards it, and with some private gifts from English friends they had half the money in hand. They intended to begin to build in the hope and trust that the balance would be subscribed.

MEDICO-LEGAL CONGRESS IN NEW YORK.

On September 4th and two following days a Medico-Legal Congress was held in New York under the auspices of the Medico-Legal Society, and Mr. Clark Bell was selected to preside over it.

The President having delivered his inaugural address, the following papers were read: By Dr. L. Forbes Winslow on the Progress of Lunacy, by Mr. Albert Bach on the Necessity of Amendment of the Law of New York appertaining to Commitments of the Insane, and by the President on the Mechanical Restraint of the Insane.

The following are the titles of some of the papers read on the subsequent days, namely: On Legal Responsibility in Inebriety, by Dr. Crothers; What Shall We Do with the Alcoholic Inebriate apparently Insane? by Dr. Norman Kerr; Suicide considered as a Mental Epidemic, by Dr. L. Forbes Winslow; Suicide Legislation and the Insanity Plea, by Gustave Boehm, a somewhat extraordinary production advocating the right of a man to commit suicide if he chooses to do so, and in the discussion which followed some of the speakers eclipsed this by advocating the right of medical men to end the agony of a patient who could not possibly recover; these views, we may add, were expressed by the legal, not medical, members of the Congress. Professor Sudduth read a paper on Hypnotism and Crime; and Professor Doremus read papers on Milk Adulteration and on two cases of Chronic Antimonial Poisoning.

At the close of the meeting the following resolutions were unanimously adopted:

That in the opinion of this Medico-legal Congress not only should the subject of medical jurisprudence be recognised in the various institutions of learning, but in the medical and law schools of this country; that such schools should include such a course in the curriculum of studies, and that examination on this subject be made necessary for graduation in either medicine or law. And

That it is the duty, and would add to the interest and benefit, of the legal and medical professions, if every national and State medical society, and every national and State bar association in the United States and British Provinces should appoint a standing committee upon medical jurisprudence.

INSPECTION OF RETREATS FOR INEBRIATES.—In the fifteenth report of the Inspector of Retreats under the Inebriates' Acts, nine institutions are reported on for 1894. The Homes referred to are situated in Chiswick, Fallowfield, Folkestone, Kingswood Park, Rickmansworth, Westgate-on-Sea, Aylesbury, Twickenham, and two at Walsall. There was licensed accommodation for 152 patients: 70 female, 82 male. During the year 133 were admitted and 127 discharged, 92 remaining in residence at the end of the year. Only one death had occurred, at Chiswick. The Inspector, Dr. Hoffman, strongly insists on the necessity for power to make the admissions compulsory as well as voluntary.

GERMAN MEDICAL OFFICERS AND THE IRON CROSS.—Of the medical officers of the German army who have received the distinction of the Iron Cross in the war of 1870 there are 943 now surviving. Of these 742 belong to Prussia, 29 to Bavaria, 44 to Saxony, 11 to Wurtemberg, 35 to Baden, 16 to Hesse, 5 to Mecklenburg-Schwerin, 1 to Mecklenburg-Strelitz, 3 to Oldenburg, 7 to Saxe-Weimar, 2 to Saxe-Meiningen, 1 to Saxe-Altenburg, 3 to Saxe-Coburg Gotha, 4 to Brunswick, 1 to Anhalt, 1 to Schwarzburg-Rudolstadt, 1 to Schwarzburg-Sonderhausen, 2 to Waldeck, 1 to Both Reuss, 4 to Bremen, 3 to Hamburg, 21 to Alsace Lorraine. Professor von Bardeleben, who recently died, had the Iron Cross of the First Class.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 4,270 births and 4,300 deaths were registered during the week ending Saturday, September 28th. The annual rate of mortality in these towns, which had been 20.9 and 19.5 per 1,000 in the two preceding weeks, further rose to 21.0 last week. The rates in the several towns ranged from 14.1 in Huddersfield, 15.0 in Croydon, and 10.1 in Leicester and in Portsmouth to 29.7 in Bolton, 29.0 in Manchester, and 30.5 in Gateshead. In the thirty-two provincial towns the mean death rate was 20.5 per 1,000, and exceeded by 1.5 the rate recorded in London, which was 19.0 per 1,000. The symtomic death rate in the thirty-three towns averaged 6.5 per 1,000, in London the death rate was 6.6 per 1,000, while it averaged 5.9 in the thirty-two provincial towns, and was highest in Bolton, Blackburn, Sunderland, and Gateshead. Measles caused a death rate of 3.7 in Blackburn; scarlet fever of 1.6 in Huddersfield; whooping-cough of 1.4 in Bradford and 2.2 in Bolton; "fever" of 1.9 in Bolton and 4.5 in Sunderland; and diarrhoea of 0.3 in Burnley, 7.0 in Bolton, 7.5 in Hull, and 7.8 in Blackburn. The 61 deaths from diphtheria in the thirty-three towns included 26 in London, 8 in West Ham, and 3 in Birmingham. Two fatal cases of erysipelas were registered in London, but not one in any of the thirty-two provincial towns. There were 221 cases of small-pox under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital on Saturday last, September 28th: 100 in London, and 121 at one of the three provincial hospitals. 21 new cases were admitted during the week, against 25, 24, and 25 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 1,000 from 2,000 to 2,700 at the end of the five preceding weeks, had fallen to 2,507 on Saturday last, September 28th; 20 new cases were admitted during the week, against 330, 365, and 341 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

During the week ending Saturday, September 28th, 1,074 births and 1,066 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 16.9 and 16.5 per 1,000 in the two preceding weeks, declined to 15.5 last week, and was 2.5 per 1,000 below the mean rate of the same period in the thirty-three large English towns. Among the Scotch towns the death rates ranged from 13.2 in Aberdeen to 20.5 in Dundee. The symtomic death rate in these towns averaged 2.7 per 1,000, the highest rates being recorded in Dundee and Greenock. The 260 deaths registered in Glasgow included 19 from diarrhoea, 4 from "fever," 8 from measles, and 2 from scarlet fever. Three fatal cases of diphtheria were recorded in Glasgow.

PROSECUTIONS UNDER THE VACCINATION ACT.

THE Thanet Board of Guardians recently addressed a communication to the Local Government Board with respect to the refusal of the Margate Borough Bench to convict in certain second vaccination prosecutions, pointing out that two authorities upon whom the duty of enforcing the law was thus brought into conflict, and asking for advice as to further proceedings. The President of the Local Government Board, in reply, forwarded to the guardians a long letter, stating that, independent of any proceedings that might be taken against a person in default under Section 29 of the Vaccination Act, 1867, the vaccination officer should be authorised to take proceedings against such person at least once, also under Section 31 of that Act. Until this had been done and a conviction obtained, the Local Government Board considered that the guardians had not done their duty. At the same time it was pointed out that where a magistrate's order had been obtained and summary proceedings taken under Section 31 of the Vaccination Act, 1867, no further proceedings should be taken by the vaccination officer without express instructions from the guardians. The idea of this was that the guardians should carefully consider with regard to each individual case the effect which a continuance of proceedings was likely to have. It was undeniable that a repetition of legal proceedings had, in numerous cases, resulted in the vaccination of the child, and it was, therefore, important that parents should be well assured that proceedings would not be lightly discontinued.

Mr. Chaplin's letter concluded: Where repeated prosecutions have failed in their object it becomes necessary to carefully consider the question whether the continuance of a fruitless contest with the parents may not have a tendency to produce mischievous results by exciting enmity with the persons prosecuted, and thus creating a more extended opposition to the law. The Board entertain no doubt that in all cases of the kind in question the guardians, having before them the preceding observations, will not fail to exercise the discretionary powers confided to them in the manner best calculated to give effect to the policy of the law.

VACCINATION AND SMALL-POX IN IRELAND.

THE *Freeman's Journal*, speaking of the epidemic of small-pox in Ireland last year and of the report of the Coombe Hospital, says: One other lesson the experiences in connection with the Coombe Hospital convey. There cannot be the slightest doubt that they prove the value and necessity of vaccination and revaccination. One fact will almost suffice. When small-pox broke out all the nurses and attendants were revaccinated except two. Both these caught the disease, but all the other officials and servants of the hospital escaped. And as regards the patients, the mortality among the vaccinated was only one-fourth that among the unvaccinated. In view of the danger that still threatens the country, we do well to adopt this means of self-defence. Those who neglected the warnings last year should be wise in time before the winter comes.

COUNTY COUNCIL ASYLUMS.

ONE moral is, says the *Daily Chronicle*, very clearly pointed out by the recent death of an asylum attendant at the hands of a lunatic, and that is that our asylums, even our well managed county council asylums, are badly understaffed. Long waiting, broken rest, and depressing surroundings, are conditions which must lead to sickness, roughness, failure to classify and watch patients; in other words, to emphasise the curative side of asylum work. Over-long hours, meagre pay, inferior food, this is the burden of several letters we have received in connection with the tragedy at Cane Hill. Under such circumstances the disorganising and harmful work which modern movement demands for the lunatically minded, and which the Council, to its credit, has constantly endeavoured to enlarge, will be sought in vain, or will produce far too scanty results.

NEW PROPOSALS FOR STORAGE CISTERNS.

A CORRESPONDENT writes: Before the Local Government Board inquiry into the water service of the East London Waterworks Company terminates there will be submitted to the inspectors some far-reaching proposals for providing house storage accommodation, with the object of ensuring a permanent domestic water supply. The suggestions have emanated from Dr. K. M. Talbot, medical officer of health for the parish of Bow, which is within the jurisdiction of the Poplar District Board of Works. By the direction of that authority, Dr. Talbot submitted at its meeting on Tuesday a special report in which are detailed the uses, advantages, and merits of the new cistern, for the invention of which he is entirely responsible. It is pointed out that the so-called constant service is a misleading term, especially after the experience of the last few months, during which there has not been any pretence to give a constant service, and on occasions this inconsistent constant service has failed altogether. Many natural causes render a constant service of water uncertain, and the community are in an insecure position, as at any time the supply may become intermittent. As a modern sanitarian, Dr. Talbot naturally abhors the old system of cisterns, and he remarks: "It is to be distinctly understood that where a real and not a false constant supply is given, cisterns are of course quite unnecessary; but seeing that in the very nature of things even a municipally could not guarantee such a real constant service, the problem arises as to how a permanent supply can be secured." This consideration, coupled with the local troubles, suggests that it is not only advisable but a necessity to provide every house which is on the constant water system with a suitable storage cistern, which will give a permanent service as distinguished from a constant service. The absence of storage accommodation in the small houses of which the Bow district is comprised, with the present insecurity of supply, may at any time be productive of slight or aggravated evils. A permanent supply under his proposals is different to a constant supply, actually as well as nominally, although the merits of a real constant supply are embodied in the permanent supply, while the dangers and drawbacks of the former are removed by the latter. If this can be satisfactorily established, then the proposals of Dr. Talbot are likely to be revolutionary. This new cistern, it is important to note, is intended to be used in connection with a constant service, and is a simple and sanitary arrangement whereby in the event of the supply becoming intermittent there will be a reserve store of water, whilst at the same time, by reason of peculiar construction, this storage house reservoir is self-cleansing and water-sealed. It is made of earthenware or other suitable material, and is of an ovoid or acorn shape, the draw-off tap being fixed at the lowest point. The water is supplied by means of a ball tap, with overflow pipe, in accordance with the 13th regulation of the Board of Trade made under the Metropolitan Water Act of 1871. This cistern can be placed in the most convenient position of the house, rendering it easy of access for inspection and attention. It is provided with a removal lid with a double lip which embraces the top edge of the cistern, the inner part being immersed in water, forming a water seal and preventing atmospheric or gaseous contamination. The interior of the reservoir—which is to be of small capacity, though the size does not interfere with the mechanical operation consequent upon water being drawn from it—is highly glazed, and, shaped as it is, suspended matter cannot be precipitated upon the sides, but must go to the outlet pipe. In a sense it is an enlargement of the service pipe, but constructed on scientific principles, which will doubtless cause it to be regarded in a different light to the cisterns of ancient type. The draw-off pipe which gives the direct service in the ordinary way can be retained, but there would not be objection to this pipe being unprovided and the whole of the water made to pass through the cistern. As a medical officer of health, Dr. Talbot says that he would have no hesitation in certifying under the Public Health Act that any house possessing this cistern as the sole medium of its water supply is a house "having a proper and sufficient supply of water." Dr. Parkes, in his *Manual of Practical Hygiene* (pp. 12-13), says he prefers the constant system for poor houses, as it leaves no loophole for inattention in the cleansing of cisterns. "Only it requires that the constant system should really fulfil the conditions laid down for it, namely, that it should deliver sufficient water and at all times, and not merely delude us with the phrase." Of the two systems, Dr. Parkes thinks that either would answer if perfectly carried out, and Dr. Talbot has taken advantage of this authority to emphasise in his report the advantages connected with his invention.

In concluding, Dr. Talbot says: "There is very naturally and very properly a prejudice in the minds of sanitarians against cisterns, but that the suggestions I have made for the establishment of a cistern of this character are to be regarded in the light of a retrograde policy is a contention with which I cannot concur. It has been demonstrated by recent events that at present there is an absolute necessity for storage accommodation. Not only so, but the great point with regard to the inevitable uncertainty under the best conditions and under the best administration, no matter what they may be of a so-called constant service also impels the conclusion that storage accommodation of some kind must be provided if these evils, which have so loudly called public attention to the question, are to be removed beyond recurrence."

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription accounts close on October 31st, and all unpaid subscriptions must be forwarded after that date to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, OCTOBER 5TH, 1895.

THE INTRODUCTORY ADDRESSES AT THE MEDICAL SCHOOLS.

THE First of October is the New Year's Day of our medical schools; and to all students, and especially to the first year's men, we wish a Happy New Year. In the introductory addresses that we publish to-day the same wish is expressed or implied. In every medical school in the kingdom the First of October is the Students' Day, and the place is full of hope for them. Even the most thoughtless of them knows that now he takes his life in his own hands, to make or waste it; and many of them come to their introductory address with hearts wholly set on work now, and success and honour hereafter.

This excellent disposition of his hearers is itself a snare in the way of him who is addressing them. They seem not to be in need of good advice; they are willing to work, and the order and details of their duties are already arranged for them. Therefore he who addresses them, knowing that he need not warn them to-day against evil ways, and knowing also that they are ready to give their whole attention to him, tends rather to speak on some theme of general interest than to give a grave moral discourse. At Leeds, for example, Dr. Leech, in an address full of learning, traced the history of medicine, far past Hippocrates, back to a thousand years before the time when Israel went out of Egypt; and he proved, as against Mr. Herbert Spencer, that our art arose not from magic and primitive priestcraft, but from honest observation of the properties of common herbs and foods. At Birmingham Dr. Percy Frankland told the whole story of Pasteur's marvellous work, and told it excellently. At the Westminster Hospital Dr. Monckton Copeman took for his subject the discovery of the thyroid extract and of the preventive serums, and the hope that in time small-pox may be brought under this treatment.

These three addresses are typical of the modern introductory address; it differs from the old-fashioned discourse in that the lecturer is unwilling to be a preacher, and be prodigal of good advice to those who do not seem to need it. These addresses are admirable in form and method, and they come with the highest authority from men who have for years worked at the subject of which they spoke. Yet it must be confessed that their themes are somewhat cold and remote; the moralities of the old introductory address are neglected; there is not enough of welcome or of advice to the students. The opening paper at the first meeting of

the Guy's Hospital Physical Society was certainly neither cold nor remote; but Mr. De'Ath, though he spoke of many things, yet spoke in praise of nothing save for a word here and there.

Many will be disposed to agree with Mr. George Pollock that there can be, perhaps, no better subject for a hospital address than the history of the hospital itself and of the great men who have worked for it. It is the place itself, with all its memories, that we love in our student days and after we have left it, and no student ought to be ignorant of the history of his hospital. The best welcome that can be given to the new student is given by him who makes him feel at home in the place.

To the older men, the remarks on idiosyncrasy, which came at the end of Mr. Pollock's address, may have seemed the most excellent part of it; but to the first year's men the story of their hospital, and of the men who made its name, must have appealed to good purpose, being itself at once a welcome and an encouragement.

But, if the lecturer has no special theme on which to speak with high authority, and if the school where he teaches is too young to have a history or a great name, there yet remains the good old fashion of the moral discourse. And it is worthy of note that of all the addresses that we publish, the only one of this form, and that a very good one, was given by Dr. Charlotte Ellaby at the London School of Medicine for Women.

Here, then, we have three kinds of introductory address. There is the modern or specialist address, setting forth the subject which by years of work the lecturer has made his own; admirable in its learning, accuracy, and fulness, but not making any direct appeal to the new student. There is the address of welcome to a great hospital, rich with the names of illustrious men. And there is the address of exhortation, which has neither the scientific interest of the modern address, nor the historical interest of Mr. Pollock's address, but it appeals directly to the spirit of those who hear it, and is liberal of those counsels of perfection that are now somewhat out of fashion.

A combination of the three forms would, perhaps, give an excellent result. In the first place every student ought to know the history of his hospital, and to be ashamed if he is wholly ignorant of it. The address, therefore, must begin with the story of the hospital's origin, its increase, and its present strength, and the names of its most illustrious men must be duly honoured. Next, that the history of our art may not be altogether ignored, Hippocrates, and he alone, must be named; he stands isolated, like Greek art: the Egyptians, Romans, and Arabians are worse than useless in an introductory address; but Hippocrates stands for all of them, and the lecturer would do well to recite the oath of Hippocrates: "With purity and with holiness I will pass my life and practise my art. . . . Whatever in my work I see or hear that ought not to be told, I will keep it secret." Then, taking a hint from the modern form of address, he might trace the history of some one discovery in medicine or in surgery, preferring some discovery not so profound as to discourage his hearers. Let him follow the way in which Mr. Godlee, some years ago, at University College, told how Ambrose Paré found out the ligature; let him set the students hoping and resolving that they too will one day make their own discoveries.

From this point the lecturer might pass by an easy transition into the third method of address, and give a good exhortation in the old-fashioned style. The plunge into hospital life is sometimes followed by a good deal of shock. When the student leaves the dissecting rooms and the laboratories, and first sees the multitudes of out-patients, casualties, and in-patients, and finds that most of the maladies of the poor are due either to the venereal diseases, or to drink, or to starvation, or to the sweating system—and he is powerless to prescribe chastity, temperance, food, and rest—then with some men the colour goes out of the world, and faith, hope, and charity all go to the wall together; or charity alone may abide, and even she will be sadly changed. The sudden sight of the bad side of things, in all their naked ugliness, is sometimes followed by this sort of shock, and for this the student must be prepared.

And for his peroration the lecturer might speak of the weal and woe of practice, the power we have for good, the certainty of a good choice; and here he can hardly fail to say the right thing. Only let him not fail to say that the great advantage of our art is neither in science, nor in money, nor in social position, but in the daily interest of isolated opportunities of doing good, and in the certainty that we have chosen a calling that can give a man peace at the last.

Finally, the admirable addresses given by Mr. Hutchinson at Liverpool, and by Dr. Mickle at the Middlesex Hospital, show that our ideal lecturer must add a warning as to the need of thorough thoughtful observation, and of such observation as shall fit the student for examination. His work may be spoiled by bookish theories and foolish generalisations, and the cure for these is observation, or by a sort of vague excited interest in strange cases, wonderful operations, and curiosities of pathology, and the cure for this is examinations.

Thus we have put together, by a process of selection, the materials for yet one more introductory address; but he who would pick and choose among the thoughts of others ought himself to possess something of their spirit, if he wishes to speak with authority as they did, or to succeed as they have succeeded.

THE RETIREMENT OF PROFESSORS.

THE report of the Committee appointed by the Treasury to consider whether there should be a term of service for professors serving under the Crown, and if so at what age, has just been published. We have taken a little time to study the decisions of the Committee, as the proposals are of no little importance, both in themselves and in the precedent they may set in the case of teachers who are not at present touched by the recommendations. The report is signed by Lord Playfair, Lord Welby, and Sir M. White Ridley. These names in themselves leave something to be desired, inasmuch as the Committee consists too strongly of public men whose minds are naturally set in the direction of practical life; and the Commissioners do, as a matter of fact, lay much stress upon the failure of teaching vigour and enthusiasm which comes about, in most men at any rate, in the later years of life. Lord Playfair is no doubt well known as a man of science, but of late years he is still better known as a statesman. Nevertheless, we are bound to admit that the report shows no forgetfulness of the truth that teaching, in any direct way, may be only a

part (and sometimes, indeed, the less important part) of the usefulness of a professor.

In the old universities we often see men actually elected to professorships at ages little short of that suggested in the report for retirement, and such appointments have shed lustre upon the universities in many instances. We are prepared to admit, however, that such advantages, found in exceptional cases, may be dearly bought by the survival in office of other men whose usefulness is a matter of tradition. These important considerations certainly have not escaped the attention of the Commissioners, and perhaps due weight is given to them. Moreover, the deference expressed to the opinions of Professor Rücker, which evidence is quoted in the report, is some guarantee that research and academic wisdom are taken into count as well as the mere teaching, which, as the Commissioners themselves point out, may be pushed forward by professors extraordinary and active demonstrators.

The Committee recommend that the age of 65 be regarded as a proper one for the retirement of professors, with a provision for continuance till the age of 70 in any special instance. One reason given for this decision seems to us a weak one; namely, that young graduates are said not to return to their universities in view of preferment there; and that they may be expected to do so if there be a definite expectation of vacancies.

Now, we suspect that there is a better reason than this, namely, the small salaries usually devoted to these chairs. Such salaries may attract men who find at middle age that a life of quiet research and pursuit of wisdom is more to their taste than to fight in the world. Men at that age find themselves in a position to judge whether they can afford, and are likely to find their happiness in such a life; one which is, in a great measure, its own reward. Under the age of 40 a man is not often ready to give up the dreams of worldly success, nor does he know what family burdens he may have to carry, or the private means he may be able to bring to supplement his salary.

There are few professorships in Great Britain upon which married men with families can, if they would, depend as a sole means of subsistence. We think that, if there be a fault in the report, it is that this pecuniary aspect of the matter is not considered.

Will able men give themselves to an academic career on salaries out of which little or no saving can be made on the certainty of being removed from their position on a pension too small to keep them in something like the social position to which they have been accustomed? The subject of retiring pensions may be dealt with elsewhere, but it does not appear in the report.

OFFICIAL INQUIRIES AND DANGEROUS TRADES.

IN addition to what has already been accomplished by Departmental Committees, the Home Secretary has appointed another Special Committee to inquire into the effects of certain dangerous trades upon the health of the work-people. As to the necessity for such there can be no doubt. To factory owners it may appear as if Parliament was interfering too much with the methods of production and restraining individual freedom, and that excessive legislation

was becoming prejudicial to commerce. There are limits on both sides. It is the duty of a Government, however, to see that in those operations which make for wealth the health of those employed is not imperilled. There are many men and women in this country whose health is so deteriorated that their life's race is practically over at the age of 40, and who, had they been sufficiently protected, might still be wage-earners instead of being a burden to their friends or to the Union. Great Britain has been the pioneer in movements which concern the health of the public, and although much still remains to be accomplished, the sanitary condition of our industries compares most favourably with that of other nations. With the view of supplying carefully sifted and scientific information, the Home Secretary has appointed a Special Committee, composed of Mr. H. J. Tennant, M.P., Captain Smith, Miss Abraham, and Professor T. Oliver of Newcastle to deal with a number of trades that have been scheduled as dangerous. All the members of the Committee have had special training for the work, having gained experience whilst previously serving on other inquiries under Mr. Asquith's directions.

The investigation about to be undertaken is practically a continuation of that in which the ex-Home Secretary not only took such an active interest, but with which his name will be for long identified. Sir Matthew White Ridley as his successor is equally strong in his conviction as to the necessity for such investigations, a circumstance which at once removes them from the sphere of party politics and gives them a truly national character.

The presence of a lady on the Committee is a novel feature. When Mr. Asquith, as Secretary of State, recommended the appointment of female factory inspectors, there were many dissentient opinions throughout the country as to the advisability of such a procedure, not less on economic than on social grounds. Lapse of time has allayed suspicions, and the high character of the work which Miss Abraham and her sister colleagues have accomplished has created a feeling of confidence in them as inspectors, and a belief that many of the minor defects of factory legislation and personal details attendant upon the ordinary routine of industrial life which told specially upon women, and which were overlooked or unrecognised, have by their influence been diminished or removed.

To this special inquiry, therefore, Miss Abraham brings considerable experience gained whilst investigating the effects of the various textile industries upon the health of women. One of the most valuable investigations which this Committee could undertake, and for which it is particularly qualified, would be a consideration of the effects of certain dangerous trades upon pregnant women and upon infant mortality. The baneful influences, for example, of phosphorus are known so far as they affect the bones of the jaw, but there has been in this country no such inquiry as that carried out by Magitot in France to illustrate the frequency of abortion in pregnant women engaged in the manufacture of matches and other industrial pursuits.

Departmental inquiries of such a nature as that of which we speak are not meant to revolutionize trade, but rather that our industries may be conducted on lines which safeguard the health of the workers. Men not less than women and children require protection.

2. The supersession of hand labour wherever possible by

machinery and the many changes which are creeping over the social life of to-day are seriously altering not only our methods of production, but throwing into the industrial arena a larger number of young people than hitherto. It is one of the complaints of trade union benefit societies that there is a gradually increasing number of the older workmen who are unable to find employment. The race is to the young and vigorous. Competition, both physical and mental, presses keener and keener; and whilst the tendency is for the number of the older hands to be diminished, there is, as Miss Collet has shown in her recent Report on the Employment of Women and Children presented to the Board of Trade, a distinct increase in the number of young people employed under the age of 15. Miss Collet's statistics do not support the current opinion that women's employment is extending, and that women are displacing men, but they demonstrate a decided increase in the number of women and girls employed under 25 years of age. Leaving aside the fact of the concurrent increase in the number of males employed between 15 and 25, the increased number of girls employed under 15 years of age calls for one remark. It is as the period of puberty is approaching that girls are sent to trades, where, either as the result of long hours, standing on their feet all day, and, it may be, breathing a vitiated atmosphere, the menstrual function becomes deranged, and the foundation of anæmia laid. It is gratifying to find from Miss Collet's report that the number of married women employed in this country is diminishing—a circumstance which points to increased material prosperity on the part of the men in the rank of life to which they belong. So far as we have been able to ascertain, it is not, however, to the disabilities created in one sex alone by dangerous industries that this inquiry will be directed. The health of men, not less than that of women and children, will be the object of investigation, and from the constitution of the Committee we may rely upon this being done in a thorough and efficient manner.

THE Harveian Oration before the Royal College of Physicians will be delivered by Dr. W. S. Church on Friday, October 18th, at 4 P.M.

THE Abernethian Society of St. Bartholomew's Hospital will open its 101st session on Thursday, October 10th, when Dr. Church will deliver the introductory address at 8 P.M. in the anatomical theatre, and the subject will be the Rise of Physiology in England and its Effect on the Practice of Medicine.

ON the evening of October 2nd, the annual smoking concert was given at the Hospital for Consumption, Brompton, by the medical staff, and was largely attended by gentlemen who have at various times held resident appointments in the hospital. The occasion was not less pleasant than similar gatherings in former years.

THE Lettsomian Lectures before the Medical Society of London will be delivered on February 13th and 17th, and March 2nd, 1896, by Mr. Watson Cheyne, F.R.S., who has chosen for his subject the Objects and Limits of Operations for Cancer. The annual oration will be delivered on May 18th by Dr. W. H. Allchin. The first general meeting of the Society will be held on October 14th, when the President, Sir J. Orlin Brown, will deliver an address.

DEATH FROM ANTHRAX.

Mr. ARTHUR LANGHAM held an inquest recently on the body of a patient who had died in Guy's Hospital from anthrax. Dr. Carpmael, the House-Surgeon, said that a *post-mortem* examination revealed the presence of anthrax bacilli all over the body, and that the case had been very severe. It was stated that the deceased, about ten days previously, had received and weighed a large cargo of skins from Russia.

THE SOCIETY OF MEDICAL PHONOGRAPHERS.

THE interesting address by Dr. W. R. Gowers, delivered at the annual meeting of the Society of Medical Phonographers, which we publish in another column, will serve to draw wide attention to the advantages which medical practitioners and clinical students may derive from the use of shorthand. The Society was only started in December last, but already numbers 178 members, and there is much other evidence of an increasing interest in the application of shorthand to medical work. The Society does much to help its members to become good phonographers by the publication of elementary handbooks and of a periodical printed in shorthand. Further information will be supplied on application to the Honorary Secretary, Dr. Neil, Warneford Asylum, Oxford.

POISONOUS EFFECTS OF BORAX.

THE extensive use of compounds containing borax, which under various names are sold for preserving foods, lends a special interest to some observations of Dr. Ch. Féré of Paris, who has used borax in the treatment of intractable cases of epilepsy, and with success in certain cases. It is true that for this purpose it was necessary to give large doses for long periods, but in the course of the trial he met with a considerable number of persons who were peculiarly susceptible to borax. In them, loss of appetite was succeeded by burning pain in the pit of the stomach, dryness of the mouth, and eventually by nausea and vomiting. Borax produces also a remarkable dryness of the skin, which is found to favour, if not to cause, various skin diseases, especially eczema. The hair also becomes dry and may fall out, causing complete baldness. The most dangerous result of the use of borax, however, is its power of producing kidney disease, or of converting a slight disorder of the kidneys into a fatal malady.

PATIENTS WANTED FOR A CONVALESCENT HOME.

USUALLY the demand made is for funds to support beds, but in the case of the recently founded Yarrow Home for Convalescent Children at Broadstairs the demand is for suitable candidates. No subscriptions are asked for or will be accepted, as the home is fully endowed by its founder, Mr. Yarrow. This home for fifty boys and fifty girls has been founded and fully provided for by private means. It is not intended for the children of the very poor, for whom provision is already fairly made by means of existing charitable agencies, but it is for the reception of children whose parents are in reduced circumstances, and are not in a position to supply to their convalescent children, entirely at their own cost, the advantage of a temporary residence at the seaside. As examples of the class from which it is intended the children shall be derived may be mentioned the minister of limited means, the widow who has seen better days, the unsuccessful professional man, the struggling artist, the clerk with a small income, the skilled foreman, all of whom are under the obligation of maintaining a respectable appearance on very restricted means. Boys between the ages of 4 and 14 years, and girls between 4 and 16 years are admitted, irrespective of nationality or creed, provided their home training has been such as to make them fit companions for other respectable and well-mannered children. No child will be admitted who has lately been the subject of scarlet fever, or ringworm, or any other infectious or contagious disease; or who comes from a

house in which there is, or has recently been, a case of infectious disease, or who still requires active medical or surgical treatment. The home will be open throughout the year, and resident certificated nurses will form part of the staff. The parents will be required to pay 5s. a week towards the maintenance of the child, in addition to its railway expenses. The fare, by special arrangement with the London, Chatham, and Dover Railway Company, is 1s. 9d. each way between London and Broadstairs. The City office (where all applications must be sent) is 73a, Queen Victoria Street, E.C.

HEROISM OF SPANISH MEDICAL OFFICERS.

THE medical officers of the Spanish army in Cuba have given some fine examples of heroism. At the action at Ocaeo, a Spanish column only 300 strong was attacked by a much superior force, and had to retire. So severely were they pressed that the wounded would have fallen into the enemy's hands, had not Dr. Urbano Orad, with 40 men, valiantly defended them under a heavy fire. He succeeded in getting them away, but was so wounded that he has since died. Before his death the cross of San Fernando was conferred on him, and this distinction, we are pleased to observe, carries with it a pension for his widow. Another medical officer, Dr. Marcial Capdevila, of the 1st battalion of the Regiment of Isabel la Católica, displayed the greatest valour in the battle of Paralejo, attending to the wounded under a heavy fire, and working so successfully, that of 89 wounded men brought in at 11 o'clock at night, all had been attended to by 3 in the morning, and although many were severely injured, only two died. Nor are these by any means isolated instances of devotion, as one of the leading political papers in Spain, *El Imparcial*, says there has hardly been an action of any importance in the war in which medical officers have not distinguished themselves by their heroic conduct in the field. They have been equally intrepid in facing the dangers of infectious disease, notably yellow fever, to which several of them have succumbed. All the lay papers speak in the highest terms of the conduct of the medical officers, and great dissatisfaction is expressed by our Spanish contemporaries that the Cross of San Hermenegildo, the highest military distinction in Spain, is by official pedantry denied to medical officers as being "non-combatants."

THE FRENCH EXPEDITION AND THE MADAGASCAR JIGGER.

IN addition to grave forms of malaria and dysentery, the French invaders of Madagascar have to contend with many minor causes of sickness: not the least important of these is that pest of African travel—the jigger. We are informed that hundreds of the soldiers are daily invalidated by this insect. Probably this is an exaggeration: but there is little doubt that indirectly the jigger will disable, and even kill, more men, and prove a more serious foe to the invader than their Malagasy opponents. The jigger—*pulex penetrans*, a small species of flea—is a present from America to Africa. Indigenous to the former continent, it was unknown in Africa prior to 1872 or 1873, when it was introduced on the West Coast. Gradually hopping its way, or carried in the feet of natives, it has spread over almost the entire continent. Not very long ago it had just reached Zanzibar, and now, it would appear, it has crossed the Mozambique Channel to Madagascar. The jigger is found principally in jungle grounds, preferring a dry, dusty soil, and being particularly fond of the ash and rubbish heaps about native huts. Here it waits its opportunity to prey (flea fashion) on man or beast. When the female is impregnated she seeks to bury herself under the skin, particularly of the toes and feet, the terminal segments of her abdomen plugging the hole by which she entered. Once buried in the skin her abdomen enlarges, attaining relatively enormous dimensions, from the development of the

ova, which now rapidly proceeds. If the insect is not carefully removed at an early stage by a small surgical operation, at the execution of which natives are from long practice particularly deft, the superjacent skin inflames and ulcerates, and so allows the intruder to drop out. When she has fallen on the ground the abdomen of the flea ruptures, and her eggs escape. In eight days' time the larvae are hatched out, and by-and-by result, after a series of metamorphoses, in a new generation of fleas. Besides the jigger it would seem that the French soldier has to contend with yet another skin pest in the shape of a hook-shaped seed belonging to a peculiar species of grass. This seed is said to work its way into the skin and give rise to a great amount of irritation and inflammation. By the pain and irritation they cause, the jigger and this grass seed are sufficiently unpleasant; but in themselves they are not directly dangerous. Some of the newspapers report that the jigger gets into the blood. This of course is absurd. The danger lies in the breach of surface and the scratching induced; for by this breach of surface a ready channel is provided for the entrance of the virus of that most painful and dangerous form of gangrene—tropical sloughing phagedena. Travellers in the tropics are only too familiar with this terrible disease. It is one of the worst afflictions the caravan, the workers in jungle lands, and the campaigner in the tropics have to contend with. It is particularly virulent in camps of overworked, underfed, malarial, scorbutic, and anemic soldiers and coolies, in whom any breach of surface is liable to become affected with this rapidly-spreading form of ulceration. A sanguineous bleb or ash-coloured slough appears at the seat of inoculation, and in a very few days vast, sloughing, stinking sores, many inches in diameter, are formed; toes and feet are often lost, and death even may result from septicæmia. When the sores at last heal, after many months of suffering, great deformity may result from loss of tissue. This very serious disease is supposed by some to be the same as the hospital gangrene, at one time so familiar in the hospitals of Europe; this is by no means established. Various micro-organisms have been incriminated, but as yet our knowledge of the bacteriology of the disease is very indefinite and incomplete.

SPECIAL HOSPITALS AND THE FIFTH YEAR.

We are glad to learn that some of the special hospitals are altering their arrangements in order to meet the needs of the fifth year's curriculum. At the Brompton Hospital the facilities for the study of diseases of the chest are to be extended by the formation of two new appointments. Clinical clerks are to be allotted to each in-patient physician, and clinical assistants to the out-patient department. In addition, all students who enter (at a small fee) for the practice of the hospital will be enabled to make use of the large amount of material (whether clinical, pathological, or bacteriological) that such a hospital affords. A course of lectures is to be given each session on the principal diseases of the thoracic organs, open to the students of the hospital and to all medical practitioners on presentation of their cards. The opening lecture of the session will be delivered by Dr. Douglas Powell on Wednesday, October 9th, at 4 p.m., on Angina Pectoris. Full information can be obtained from the Secretary of the hospital, or from the dean of the schools at any of the metropolitan hospitals.

A SUGGESTION FOR THE MEDICAL SOCIETIES.

A Correspondent writes: May I draw attention to a difficulty which stands in the way of the clinical investigation of some of the rarer forms of disease? We are told, and I believe it is the fact, that at the present time no organisation exists by which anyone engaged in any inquiry regarding any special malady can find out where among the large number of hospitals, infirmaries, and other institutions which exist in London other cases of the same nature or of allied character

exist. People taking up the study of any of the larger groups or divisions into which diseases are commonly classified do not feel the difficulty, but when it is a matter of rare diseases or curious pathological conditions an investigator, however carefully he may describe the few instances that come before him, finds it next to impossible to discover others of similar nature with which to compare them. Yet amid the vast invalid population of London it ought to be possible to match almost any case, however strange. There is no doubt that members of the several medical societies, when they know a fellow member is interested in any subject, are willing enough to tell him of illustrative cases, but only those who are well known are able to get this assistance, and the suggestion is made that this sort of co-operation might be organised on a more methodical basis. At first sight it might appear that by the use of the correspondence columns of the *BRITISH MEDICAL JOURNAL*, the difficulty might be met, but I question whether its circulation is not too wide to make its columns quite appropriate for this purpose. Any public announcement that a particular case could be seen in a ward in a particular institution might lead to embarrassment, and would be very likely to be resented both by the authorities of the hospital and by the patient himself. This, however, would not apply to the institution of inquiry lists at such a centre of medical work as the rooms of the Royal Medical and Chirurgical Society. Most men who are attached to hospitals in London are connected with one or other of the societies which meet there; and it would be a practical and useful step if arrangements could be made by which investigators working at any special cases might be informed where similar or analogous ones might be met with.

THE SICK POOR IN IRISH WORKHOUSES: THE NORTH DUBLIN UNION.

The North Dublin Union Workhouse, like the sister union of the south of the city, suggests the desirability of subdivision. If the sick department were, as in London and the larger English provincial cities, entirely separated from the administration of the workhouse proper, and worked on the lines of a general hospital, not the sick alone but also the infirm and the idiots would benefit by the change, as the latter might then succeed to the present sick wards. The actual condition of the two last-named classes is most unsatisfactory. The lot of the aged and of the chronic invalids is unspeakably dreary, and the picture given of the lunatic department recalls the accounts of our asylums before the appointment of the Lunacy Commissioners. Short of such drastic measures as new quarters and complete reorganisation, however, much might be done by increasing the staff and by abolishing the pauper nursing. We hope that the detailed criticisms of our Commissioner may induce the Dublin ratepayers to look into the condition of the unfortunate paupers for whom they are ultimately responsible. A more humane and more enlightened administration of the Poor Law would react for good on the whole community, and it is a reform which will be carried out as soon as public opinion is roused to demand it.

THE JENNER RELICS AND THE JENNER CENTENARY.

The near approach of the date (May 14th, 1896) when a century will have elapsed since Jenner's famous and decisive experiment in vaccination was performed has, as already stated, led the National Health Society of Russia to organise an exhibition, to be held in St. Petersburg, of objects which relate to the great discovery and its author. Prizes of considerable value are offered for the best works on the subject of vaccination, and the opportunity is being taken to collect and publish materials for histories of its practice in Russia and Western Europe. Jenner's works are to be translated into and published in

Russian; also his biography accompanied with a portrait; and a commemorative meeting will be held on the day of the centenary. The competitions mentioned will be closed on March 2nd (14th), 1896. In Bristol a subscription has been opened to purchase the famous collection of Jenner relics formed by Mr. Mockler, of Wotton-under-Edge, shown by him in the Bristol exhibition of 1893, and again in London last year, so as to secure its retention in the museum there or some other public institution. It would seem that this most valuable collection of diplomas, documents, manuscripts, printed works, portraits, and objects personal to the illustrious man was offered to the Council of the Royal College of Surgeons and to that of the Royal College of Physicians, but declined for want of accommodation. It should not be left to the citizens and members of the profession in Gloucestershire to be the sole contributors to what should be a national object. It would be a national disgrace were the collection to be allowed to be dispersed or removed to a foreign country.

MEDICAL ETIQUETTE AND THE PUBLIC.

THE *Echo* recently published a reckless paragraph on the death of Mrs. Fletcher at Holloway, containing statements which we are able to say, on the best authority, are wholly unfounded. It was not a matter of medical etiquette that Dr. Whitehead was obliged to ask Dr. Wight's leave to take sole charge of the patient, for Dr. Wight and Dr. Whitehead were already both of them attending her; it was simply a matter of straightforward dealing. In two hours' time after Mrs. Fletcher had been delivered Dr. Whitehead took sole charge of her; he sent at once for Dr. Griffith, and everything was done that could possibly be done to save her life. It is not true that medical etiquette had anything to do with the fatal issue of the case. It is not true that the motto of our profession is to consider our fees before our patients. Nor is it true that a patient is not at liberty to dismiss his medical attendant whenever he likes. And as regards medical etiquette one thing is certain, that if the profession were not bound by its rules the public would suffer past all bearing. Every profession must have its own rules of honour, and without these rules there would be constant fighting, dishonesty, and quackery among us. But as regards the case to which the *Echo* made reference, the plain truth is that medical etiquette did not interfere with the treatment of the case, and had absolutely nothing to do with the issue of it.

LONDON POST-GRADUATE COURSE.

THE winter term will commence on Monday next, and the instruction will be carried on at the Hospital for Sick Children (Great Ormond Street), at the National Hospital for the Paralyzed and Epileptic (Queen Square), at the Royal London Ophthalmic Hospital (Moorfields), at Bethlem Royal Hospital for Lunatics, at the London Throat Hospital, at the Bacteriological Laboratory, King's College, and at the Central London Sick Asylum. The work is thoroughly practical and suited to the needs of the practitioner. The "diary" is so arranged that all the lectures can be attended with ease, and time left for a large amount of hospital practice. One or more courses can be taken at the option of the members, or all the lectures for one or more weeks can be entered for. Opportunity for doing such an amount of work as each can arrange for is thus facilitated. A prospectus can be had from Dr. Fletcher Little, Secretary, 32, Harley Street, W.

DAIRY FARMERS AS SCAVENGERS.

DR. JOHN BROWN, the health officer of Bacup, draws attention in his report for 1894 to a very important matter connected with the administration of the Public Health Acts alike in Bacup and in many other Lancashire sanitary districts. The occurrence of cases of typhoid fever in the spring of last year led to inquiry as to causation, and in the

end the outbreak was traced to the agency of milk. The farmer of the dairy farm whence the implicated milk was distributed was a scavenger of night soil, and had in the course of his business as such to remove the excreta both of infectious and non-infectious cases, and had, as a matter of fact, been known to remove the excreta of a typhoid patient not very long prior to the outbreak in question. The danger to the public health of such procedure can well be imagined, and, indeed, it needs but little stretch of imagination to picture a farmer proceeding from a round of scavenging to the process of milking his cattle, and in this way communicating to his milk produce the specific infective property which will enable the milk to spread disease and probably death among his customers. The dual position of dairy farmer and scavenger should not be allowed for one moment. It is not alone by means of the personal contact with the procedures of milking by the farmer or his staff of scavengers that danger is to be apprehended; there is the further danger of the actual material from deposited night soil in the vicinity of the farm premises gaining access to the milk cans or the milk itself in storehouses, and so on. However the matter be looked at it appears a dangerous combination of offices, and we trust that wherever it exists steps will speedily be adopted to disassociate the incongruous callings.

WATERBORNE CHOLERA.

COLONEL H. WYLIE, British Resident in Nepal, in regard to the prevention of cholera, states in the *Times* his experience of one large eastern city, Khatmandu. Cholera, he says, was a perfect plague in this city until 1891, when His Excellency Maharajah Sir Bir Shumsher Jung, the Prime Minister of Nepal, introduced, at a cost of over six lakhs of rupees, a plentiful supply of pure water, brought in pipes from mountains six miles distant and distributed by means of standards and taps. Since then cholera has been absolutely non-existent in the city of Khatmandu, although it has broken out virulently in other parts of the Nepal Valley, including a very severe epidemic in the town of Patan, which is only two miles distant from here. He adds that the sanitation of Khatmandu leaves everything to be desired, and that this grievance has been one of many years' standing.

DEFECTS OF IRISH WORKHOUSES.

A report on the condition of Irish workhouse infirmaries was read before a meeting of the Council of the Irish Medical Association on August 29th, 1895, by Dr. Moorhead, Honorary Secretary of the Workhouse Medical Officers' Association. It contains a digest of the various reports furnished by the medical officers of forty-five unions to their respective boards, and of the action or non-action taken by these bodies in consequence thereof, as reported in the local newspapers. These reports, it may be remembered, were furnished by the medical officers in response to an instruction issued by the Local Government Board to the Boards of Guardians charging them to inform themselves of the state of their infirmaries. Dr. Moorhead has tabulated the replies, and in a condensed form lays before the Council the results arrived at. By far the largest number of infirmaries, namely, twenty-nine, are classed as "those in which proper sanitary appliances, efficient nursing, and suitable furniture are absent." On looking through the material on which this classification is based, we are astonished to see the very low standard that is thought sufficient in these infirmaries, and we note, with regret, the attitude of antagonism between the doctor who is doing his utmost to improve the condition of the patients committed to his care and the authority who is responsible for the efficiency of the workhouse. Dr. Moorhead, however, introduces a sympathetic sentence into his report which those who are working at this reform should lay to heart: "Even when willing to set their houses in order, many of them do not know how to set about it, and in this I think they are entitled to our consideration and

forbearance; for having no knowledge of sanitary science or modern hospital requirements, they are called upon to effect large changes, and have no one in authority to show them how to go about it or direct them what to do."

IRISH WORKHOUSE HOSPITALS.

THE Local Government Board in Ireland has taken up the question of hospital improvement with some vigour. It has already dissolved an obstinate Board of Guardians, and it is unlikely that the process will need to be repeated elsewhere. At Longford the other day the Board addressed the guardians on the subject of reforms. They required the appointment of three under nurses, the improvement of sanitary arrangements, and a supply of new iron bedsteads with wire wove mattresses for the infirmary. The guardians resolved that the doctor should employ a second fever nurse when required, and that one assistant nurse should be employed at £5 per annum! A few beds were ordered, but before that was done the inspector, Major Fair, had been called a liar by various members of the Board. The Local Government Board will have public support in any effort to deal with persons of this type. The effort at "improvement" is too ridiculous.

ENTERIC FEVER IN INDIA.

THE *Broad Arrow* says: "Enteric fever is causing havoc among our young officers at Bangalore. The recent death of Second Lieutenant MacTier, of the Dorsetshire Regiment, at the Station Hospital, where he was under treatment, brings the mortality up to three from this disease, while five deaths in all have occurred among the subalterns of the garrison. All officers who have been quartered at Bangalore are well aware that the drinking water for the cantonment is derived from a tank supplied by an open channel which passes through a native bazaar, kept clean by sweepers. Forming part of the wall of the supply channel is the main sewer from the same area. The sewer is so ingeniously arranged that when overcharged with storm water relief is obtained by discharge into the water-supply channel, and thus into the tank. These facts were laid before the Indian Medical Congress by the Sanitary Commissioner, Madras, in an instructive address on Sanitation in India." As before noticed in a letter from a correspondent, the policy of the tea kettle is here carried out, and the epidemic of typhoid stopped for a time. None the less is it necessary that means should be taken for the uniform purification of the water supply. It will be satisfactory to learn that either perfectly pure sources have been found, or that Pasteur filters have been brought systematically into use.

LUNATICS AT LARGE.

THE recent murderous assaults made by several lunatics at large, and ending in the loss of several lives and the severe injury of several other persons, has led to some discussion as to the provisions of the present Lunacy Act, and particularly of its provisions which lead to the discharge of patients who are not properly recovered. These provisions, which render it very difficult for an asylum medical officer to retain certain cases which, when discharged, are very apt to relapse and become dangerous, are certainly very much open to question. Like other provisions, these were inserted as a consequence of the agitation about alleged unnecessary or improper detention in asylums and interference with the liberty of the subject. And there must be one or other of two things—either power to detain persons who, although better than they were, are liable at any time to become more disturbed mentally and to commit some act of frightful violence, or else for the public to submit to be compelled to deal as best it may with such acts of violence when they occur. This latter, however, is rather hard on the unoffending members of the general public who happen to become the objects of the outbreak of murderous violence when it occurs, and for no fault of their own. The public

cannot have its cake and eat it too. Some share in the matter is due to the competition to discharge a bigger percentage of so-called "cures" than other institutions secure. The discharge of some lunatics, and their return to their homes to beget a generation largely consisting of weak-minded or insane or criminal persons is in every way most pernicious and disastrous.

LONG HOURS AND MENTAL STRAIN.

LONG hours of continuous, or nearly continuous, work place a severe strain upon the constitution quite apart from the actual amount of physical labour involved. On several occasions there has been good reason to suppose that accidents on railways have been more or less directly due to the physical and mental strain produced by exceptionally long hours of duty. This danger will, it may be hoped, be strongly impressed on the managers of railway companies by Major Marindin's report to the Board of Trade as to the collision which occurred last month on the Dublin Wicklow and Wexford Railway. The line was single, and the accident appears to have been due to the driver of a train starting without the staff. The Inspector, however, calls special attention to the fact that this man had been at work for too many hours during the day. He had commenced duty at 8 A.M., and though he was off duty from noon till 4 P.M., and from 4.45 P.M. to 6.55 P.M., his fatal mistake was made when he had been seventeen hours on duty with these intervals of rest. Major Marindin attributes the accident partly to his being tired out, and points out that the cases of the two guards were worse, for one had been at work for nineteen hours, and the other for twenty minutes longer. "The running of trains," he concludes, "with men worn out by long hours, is a distinct danger to the public, as well as an injustice to the men, and should under no circumstances be countenanced." The human brain is a wonderful instrument, but like all living structures it cannot be depended upon to discharge its functions with precision unless at regular intervals reasonable intervals of repose are allowed for recuperation. From this point of view the reasonable amount of work to be expected from a man in good health cannot be gauged by the week. The apportionment of sleep and work must be governed by the day. It is a matter far more of mental than of bodily fatigue. It is hardly a paradox to say that the better the man the greater the liability to temporary brain failure. The deeper his sense of responsibility, the higher his feeling of duty, the more quickly must exhaustion ensue. In railway work we have that combination of hard work and anxiety which most quickly produces fatigue.

"WHITE SLAVES" IN HOSPITALS.

THE *Daily News* has opened its columns to a correspondence on the conditions under which nurses are supposed to work in our general hospitals. As is usual when professional subjects are handled in a non-professional journal a great deal of irrelevant matter has been dragged into the argument, and generalised statements have taken the place of facts; as we have read the letters, in some of which some astounding charges have been made against the hospital authorities under cover of an anonymous signature, we felt that the cause would have gained if the name of the writer and of the hospital had been given, otherwise these letters are valueless as evidence. Much stress has been laid upon the long hours of work for the nurses, both in the leaders and in the letters; but these we take it are masculine criticisms by those who understand hours of work to mean the same as those continuous hours exacted of a clerk or a mason; a nurse when on duty is in a position analogous to a soldier in the guard-room—she is to be at her post ready if wanted, but at leisure it may be for half or less of these hours. We feel that in the matter of food, recreation, and sleep there is room for improvement, because the average official is too apt to allow these import-

ant questions to drift into routine, and does not give that individual attention to the domestic side of hospital life on which the well-being of the staff turns. Then there is a tendency to encourage young and immature women to enter on this life, which is one that can only be borne by the healthy and well-seasoned; is not the rage for the young nurse on the private staff to a certain extent answerable for the physical failures in the hospital course of training? These grumbles evidence something wrong somewhere, and it is the business of the officials and the authorities to look into the matter, and remove every justifiable ground of complaint among the probationers.

THE PATHOLOGICAL SOCIETY OF LONDON.

The first meeting of this Society will be held on October 15th, but the President, Mr. Henry T. Buthin, has decided to postpone his presidential address until next year, when the Society will celebrate its fiftieth anniversary.

DEATH OF SIR THOMAS LONGMORE, C.B.

It is with extreme regret we announce the sudden death of Surgeon-General Sir Thomas Longmore, C.B., Honorary Physician to the Queen, and for long Professor of Military Surgery in the Army Medical School, Netley. Sir Thomas Longmore was staying at Swanage, and appeared to be in his usual health when he saw his son off by train in the early morning, and within two hours he was dead. Of Sir Thomas Longmore's long, honourable, and useful career we hope to give an adequate account in an early issue.

SURGICAL MECHANICS.

A novel experiment is about to be made in connection with the Institute of Dental Technology. A course of manual training for surgeons will be commenced on October 15th and will be continued each Tuesday and Thursday evening until December 19th. The course is intended to afford an opportunity for practical work at the bench, vice, lathe, and forge, and in the artistic reproduction of cases. The workshops of the Institute at 4, Langham Chambers, W., are fully equipped, and the services of a skilled staff of instructors will be utilised according to individual requirements. A detailed syllabus has been issued and can be obtained from the Principal, Dr. George Cunningham, I.D.S. Eng., or from Mr. H. P. Deane, F.R.C.S., Assistant-Surgeon to the London Hospital. This first course is of a tentative character, and those engaged in the teaching of surgery are specially invited to attend with a view to ascertain whether such a course would be likely to benefit senior students and qualified practitioners. The hours named are from 8 to 10 P.M., but if those who attend the class are likely to find the hours from 5 to 7 P.M. more convenient this change will be made.

THE CORRECTION OF THE "MEDICAL REGISTER."

We desire to call general attention to the notice in our advertisement columns, issued by the General Medical Council. It is a reminder that every registered practitioner should be careful to send to the Branch Registrar by whom he was originally registered immediate notice of any change in his address, in order that such change may be duly inserted in the *Medical Register*, and also to answer at once any letter of inquiry that may have been sent to him in regard thereto. Failing attention to this, a practitioner is liable to have his name erased from the *Medical Register*. Any practitioner on whom this misfortune has already fallen owing to an earlier oversight should make immediate application for restoration to the Branch Registrar by whom he was originally registered. Appended to this notice is a further statement containing the resolutions of the General Medical Council and its Executive Committee in regard to covering unqualified persons and the employment of unqualified assistants. With regard to the first point, it is

held that a registered practitioner covers an unregistered person when he does, or assists in doing, or is party to, any act which enables such unqualified person to practise as if he were duly qualified. As to the employment of unqualified assistants, a registered medical practitioner renders himself liable to the censure of the General Medical Council if he employs an unqualified assistant on his behalf, or for his benefit, either in complete substitution for his own services, or under circumstances in which due personal supervision and control are not, or cannot be, exercised by the registered practitioner himself. On many occasions the Council has taken action in accordance with these resolutions, and it is obviously the duty of every qualified practitioner, in the interests of the profession to which he belongs not less than his own, to act up to their spirit.

THE MORAL OF JANE CAKEBREAD'S STORY.

We have on various occasions referred to the distressing case of Jane Cakebread, who, now considerably over 60 years of age, is no sooner out of prison than she yields to her diseased impulse to intoxication, to be brought again before a police court. We commented on a well-meant attempt to detain her for a year (a ridiculously short term for such a confirmed case) in a home for inebriates; but the unhappy victim of a persistent disease would have none of it, and on her 25th conviction has been sentenced to hard labour for a month. The obvious moral of this police-court repeater's career is the necessity of compulsory detention. She is but a type of hundreds of other male and female inebriates, some offenders more unknown to the courts, who can be treated only by involuntary therapeutic seclusion. The late Government saw this, and we have great hope that the present Cabinet will adopt a continuous policy on this matter. This distressful offender against the law has brought a scandal on our legal procedure. Penal measures have failed, why not give compulsory remedial treatment a chance? We earnestly urge all our readers to point the moral of Jane Cakebread's 25th convictions in personal or written appeals to their members of Parliament, and to every member of the Ministry.

CHOLERA AS A TEST OF SANITATION.

Dr. THORNE THORNE, in his last report to the Local Government Board, says: "In my report on cholera in England during 1893 I pointed out that of the 61 localities in which cholera appeared in this country the disease was limited in 42, or nearly 60 percent. of the whole, to one single attack; and this was the case although as regards the majority of the attacks the disease must be looked upon as having been true cholera of the Asiatic type, whether it be judged by its clinical symptoms, by the outcome of bacteriological research, or by the heavy rate of mortality which it occasioned. Such a result, altogether unique in the history of cholera, was, I believe, largely due to the improved sanitary circumstances of England. But it is certain that if, in the cases of public water service I have been considering, the specific material which found access to the waters had been that of cholera instead of enteric fever, our cholera history for 1893 would have been the record of even greater disaster brought about in most of the cases by deliberate neglect. Even as the matter stands such instances of neglect remain a matter of reproach to our local sanitary administration."

REMINISCENCES OF PROFESSOR HUXLEY.

In the *North American Review* for September Sir William Flower gives some interesting personal reminiscences of Professor Huxley, gathered, as he tells us, during a friendship of nearly forty years. He became acquainted with Huxley through George Busk, whose name, it may be mentioned, is consistently misprinted Busk throughout—a testimony to the duration of scientific fame which may be commended to the notice of ambitious youth. The whole article, however

is a curious specimen of careless proof-reading. The story of Huxley's marriage, as told by Sir William Flower, supplies an element of romance which one hardly looks for in the life of a scientific man. When the *Battledore* was in Sydney Harbour the officers were invited to a ball, and among those who went was young Huxley. There he met his matrimonial fate in the form of a young lady whose parents resided at Sydney. A few days afterwards they became engaged, and within a fortnight of the young people's first meeting the *Battledore* sailed for the Tower Straits to complete the survey of the North Coast of Australia, all communication between them being cut off for months at a time. It was seven years before the lovers saw each other again, and at the end of that time the constancy of the scientific Jacob was rewarded by an appointment to the School of Mines, which enabled him to marry. The union was a very happy one, and although they had at first many household troubles and cares to contend with, a large family of young children, much ill health, and not very abundant means, through it all Huxley's patience and sweetness were admirable. "The fierce and redoubtable antagonist in the battle-field of scientific or theological controversy was all love and gentleness at home." Huxley's early tastes were, as he himself has told us, not for natural history but for engineering. From an early age he also took an interest in literature, the strength of which may be estimated from the fact that while at sea he taught himself Latin with the object of being able to read Dante in the original. Unlike other zoologists, Huxley was never a collector; he only cared for a specimen according to the facilities it afforded for investigation. Sir William Flower believes he never made a preparation of any kind, and he cared little for dissections sealed down in bottles. "In dissecting, as in everything else, he was a very rapid worker, going straight to the point he wished to ascertain with a firm and steady hand, never diverted into side issues, nor wasting any time in unnecessary polishing up for the sake of appearances—the very opposite, in fact, to what is commonly known as 'finikin.'" Sir William Flower thinks Huxley might have been a great artist, but he never found time to cultivate his faculties in that direction. He was, we are told, "free from a quality which paralyses the effective action of many men of great mental capacity—the faculty of seeing something at least of both sides of a case at the same time." He was also a man with "some strong prejudices against doctrines, against institutions, and against individuals." This gave his teaching and his writing the quality of "cock-sureness," which was an offence to many, but which was effective in controversy where he fought dogmatism with its own weapons. Huxley, though much of his intellectual life was devoted to fighting theology, was a more truly religious man than many theologians, and Sir William Flower bears witness that no one could be intimate with him without feeling that he possessed a deep reverence for "whatever things are true, whatever things are honest, whatever things are just, whatever things are pure, whatever things are lovely, whatever things are of good report," and hatred of whatever is the reverse of this, and that "although he found difficulty in expressing it in definite words, he had a pervading sense of adoration of the infinite, very much akin to the highest religion."

PASTEUR AND HAFKINE.

AN impressive and instructive tribute to the memory of Pasteur at the moment that the tomb is closing over him may be found in the results, of which we last week gave a full report, of the admirable work of Dr. Hafkine in India. Not only was Hafkine a pupil and assistant of Pasteur's at the Pasteur Institute, where he was trained in bacteriology and where he carried out all his researches on the prevention of cholera; but the cost of his disinterested journey to India was in the first instance largely subsidised by M.

Pasteur from his private resources. When M. Pasteur and Dr. Hafkine first communicated with the Editor of this JOURNAL on the subject of his researches, of which we gave at the time a full account, Mr. Ernest Hart invited Dr. Hafkine to come first to London before starting to India and to give public demonstrations of his method and of the means of preparing his preventive vaccine. Dr. Hafkine accepted the invitation, and it will be remembered that we arranged with Dr. Sims Woodhead, (the superintendent of the laboratory of the Royal College of Surgeons on the Embankment) for a public lecture and demonstration to which the leading physicians of London were invited, and which attracted much attention here. Subsequently an appeal was made to the Secretary of State for India, who did not, however, feel justified in any way supplementing the private expenditure of M. Pasteur and of Dr. Hafkine in this great work undertaken for the benefit especially of our great Indian Empire. It is at the moment of Pasteur's death, and after a course of labour of the most unremitting and devoted character, which has seriously injured his health, that this devoted disciple of Pasteur is returning to Europe after having expended three years of labour and a very large sum from his own private purse in carrying out inoculations on a vast scale, of which it is officially announced that the statistical results in Calcutta alone have shown that inoculated persons are twenty times safer than uninoculated. "The results may be briefly stated as follows. Amongst persons 'protected by the first inoculation only 22 per cent. were attacked and died; among those who had undergone complete second inoculation, there were no cases and no deaths.'" This latest posthumous result of the beneficent labours of Pasteur is still in a tentative state, but already the results are sufficiently proved as vastly wide applications of the Pasteur principle and methods, and the unflinching advice and munificence with which the labours of the great master are continued by his able and self-sacrificing pupils.

QUARANTINE AT GIBRALTAR.

AFTER all that England has done for the abolition of quarantine it is interesting and by no means reassuring to hear of the imposition of quarantine at Gibraltar on all persons arriving from Morocco ports since the reported outbreak of cholera at Tangier. It is stated that on receipt of a telegram from Tangier officially declaring Asiatic cholera to be present among the native population, the Gibraltar Health Board immediately ordered a seven days' quarantine on arrivals from Ceuta and other Morocco ports, while the Deputy Governor, Sir Frederic Carrington, has prohibited the entry into Gibraltar of any person who has within 21 days been at Tangier. Thus easily do we drift back into the dark ages, and lay ourselves open to the reproach of insincerity. The quarantine has caused no small inconvenience to the many English from the Rock who have been spending their holiday in Morocco, for nearly all the steamers connecting with Europe have ceased to run, and thus many people have been "blocked" at the other side, and have been entirely unable to extricate themselves from the midst of the epidemic. A party of English, including Colonel Markwick and his family, are stated to have been forced to charter a steamer to convey them across to Gibraltar, where they now lie in the bay in quarantine for three weeks. Surely it is derogatory to England's position in sanitary matters that such proceedings should receive official sanction.

PRESENTATION.—Dr. F. R. Garland has been presented with a handsome clock by the inhabitants of Gethse as a parting recognition of his services during the last three years. Mrs. Garland was also presented with a silver tea service.

The Virginia Medical Society has admitted its first lady member in the person of Dr. Catherine C. Emory. The North Carolina Medical Society has one female member, Dr. Annie L. Alexander, who was admitted as long ago as 1886.

BOMBAY MUSSULMANS AND THE PILGRIM SHIPS BILL.

It is with a sense of some considerable disappointment that we have read the memorial adopted at a meeting of Mohammedans in Bombay and addressed to the Viceroy of India on the subject of the Pilgrim Ships Bill which is now under the consideration of the Government of India. It is not because we have any particular views as regards the Bill as a whole that we regret the attitude adopted, but because we had hoped that where definite sanitary gain was in question the Mohammedans would have been as anxious to promote such gain at the Indian end of the journey as they evidently were to secure it at the Red Sea end when they gave their support to Mr. Ernest Hart during his last visit to India. It was then practically decided that the Mohammedans themselves were to exercise pressure on the Sultan, as head of their religion, to secure sanitary measures and to prevent needless death in connection with Kamaran, Jeddah, and the Holy Places. But we fear any such representations will lose their principal force if the views embodied in the memorial in question come to be adopted.

In the first place the Mohammedans of Bombay object to the provision, under the Bill, of 16 square feet per pilgrim between decks, instead of 9 square feet as at present; and they contend that this provision, which is based on a promise made by the British and Indian delegates at the Paris Conference, is unnecessary, because 6 square feet are allowed on the upper deck as well. This view has been adopted by many, and it has been further asserted that if the 9 square feet serve for troops they are sufficient for pilgrims. But there is no parallel between the journeys of well-organised and properly-disciplined healthy men, under the immediate supervision of skilled medical officers, and the horde of semi-destitute pilgrims who are often found on pilgrim ships. Then, again, it is well known that at certain seasons the upper deck space is not available for sleeping, being either saturated by heavy rains or washed with waves. And yet, in the face of these considerations, the meeting in question preferred an allowance of 9 square feet to 16 per pilgrim, and this even where the larger space was to be allowed, under the Convention, to serve for the deposit of personal luggage or such things as come under the term "petits baggages." Let us consider what 9 square feet per pilgrim means when the monsoon is blowing. It means that at a time when all must lie between decks, the space for each individual is less than 5 feet long by 2 feet broad; and that many of the individuals in question are aged, ailing, and sea sick. Anything more utterly opposed to a condition of healthiness it is all but impossible to conceive; and if the Bombay Mohammedans definitely take up the line that 9 square feet suffice as a proper sanitary standard, then they had better base their arguments and appeals on behalf of better sanitation in Arabia and the Red Sea on some other ground than that of health. The experience of single pilgrimages is of little value in judging of the space needed, for much depends on the season and the weather during which the voyage in connection with the movable feast in question takes place.

Then, again, the meeting objected to the payment of the sanitary taxes at the outset of the journey, and their being handed over to the Turkish authorities by the captain of the vessel. This clause was inserted in order to meet the complaint that so large a number of the pilgrims are in a destitute condition, and that this very destitution constitutes one of the principal dangers of the pilgrimage. This condition of pauperism is practically admitted by the Bombay meeting, the members of which ask that, whatever is done in this respect, exemption should be claimed at the rate of at least 40 per cent., because the Turkish authorities have never "been able to collect the sanitary taxes from more than half the people," and this by reason of the poverty of the pilgrims. We have no wish to secure for the extortionate Turkish authorities a single rupee in excess of that which they have got heretofore; but if health considerations are to influence the arrangements of this pilgrimage, then we cannot but feel convinced that something in the direction indicated ought to be done to prevent so large a following of destitute people becoming a danger to

others, and a prey to death along the pilgrim route. The question could be solved in just the same way as that of the pilgrims' fare by steamer is solved. Whether destitute or not the pilgrim pays this in advance, by the aid of others.

As regards these and many other points, the memorialists plead with the Indian Government that they should have regard to the religious susceptibilities of their Mohammedan population, and that they should not take steps which will interfere with religious usages and practices, or with religious freedom. We have the fullest sympathy with the maintenance of the widest freedom in connection with the performance of religious rites, including the Mecca pilgrimage; but when we remember how utterly this principle is disregarded by the Turkish authorities we are almost astonished to find such language addressed to the Viceroy of a Monarch who stands first in the world as the upholder of religious freedom. A requirement as to 16 square feet, which will perhaps just allow an adult pilgrim to lie down, is no greater violation of religious freedom than is the one as to 9 feet now insisted on, nor is the collection of so much of the sanitary tax as must be paid a greater violation of the right to perform a religious duty than are other restrictions which cost money and which must be settled by the pilgrim before he starts. The Netherlands Government demand far more than this without being accused of religious oppression and without their Government being told that they must "bear the odium" of those requirements which they insist on for the benefit of their Mohammedan population generally.

If such words had been addressed to the Mohammedan officials who insist on payments at a rate which the memorialists hold to be extortionate and who block the way to Mecca at every portal by means of a money tax then we could have understood the accusation as to interference with religious freedom. It is well known that the sanitary taxes enforced in the Red Sea and Arabia are used for a very different purpose than that of the welfare of the pilgrims, and yet the Sultan's officials are not accused of preventing poor people from reaching that which they fully "believe.....to be the surest way to salvation." The action taken by the British Government has in this matter always been aimed to secure benefit for the health and lives of our Mohammedan fellow subjects; and we cannot but think that some outside influence, such as a commercial one, in connection with pilgrim shippers has unknowingly been utilised to raise objection on the part of the Bombay meeting to the principle of measures such as those to which we have adverted. According to the united voice of the Governments assembled at Paris, our Government is doing a wrong to the pilgrimage by the laxity of regulations such as are deemed necessary in the interests of those who desire to visit Mecca; and it is difficult to avoid the conclusion that some modifications in the direction of modern public health requirements are really needed.

We have dealt with this subject at some length, because we cannot but feel that if the attitude of our Bombay fellow-subjects is maintained, they will come to regret having taken it up. They plead for improvements at Kamaran, and for the abolition of quarantine restrictions which produce infinitely more cholera than they have ever stopped. We are heartily with them. We look upon Kamaran and other like depots as primarily serving to secure a money-tax, and as often ending in a blood-tax too. Many have left their dead bodies at Kamaran who would have returned to their Indian homes with the proud distinction of Hajis if that mischievous quarantine station had never existed. But, if it is ever to be abolished, and if Jeddah and other places where the pilgrims must land or stay are ever to be so dealt with as to have some approach to sanitary decency, those ends will not be attained by declamations as to interference with religious liberty because a Bill is brought in to provide that when at sea, and especially in bad weather, each pilgrim shall have between decks the very small allowance of a space covering a few inches over 5 feet long by 3 feet wide for himself and his personal encumbrances. We fear this aspect of the question is not being sufficiently taken into account by those of our Mohammedan fellow-subjects who are earnestly desirous of saving some at least of that utter waste of health and life which now accompanies the pilgrimage to Mecca, and much of which

is certainly preventable by the adoption of reasonable sanitary measures.

THE CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The annual calendar has just been published by the Council of the College. From it we ascertain the following facts, namely,—There are 1,100 Fellows on the roll of the College (against 1,144 last year), of whom 947 obtained the Fellowship by examination, 15 were elected as Members of twenty years' standing under section 5 of Chapter 15 Victoria, and 2 are *ad eundem* Fellows. There are 16,816 Members and 645 Licentiates in midwifery. The Licentiates in dental surgery are stated to number 1,007. Holders of the diploma of public health (granted by the Royal Colleges of Physicians of London and of Surgeons of England) number 215.

During the past collegiate year 577 candidates presented themselves for examination in Elementary Anatomy, of whom 473 passed and 104 were referred; 82 candidates presented themselves in Elementary Physiology, 55 of whom passed and 27 were referred; 488 candidates presented themselves in Elementary Biology, of whom 327 passed and 161 were referred. The examiners are appointed in conjunction with the Royal College of Physicians of London, under the scheme for an Examining Board for England. The fees paid by candidates for this examination amounted to £2,991 8s. 9d., the examiners receiving in fees £431 5s. Of 609 candidates who presented themselves in Chemistry 355 passed and 254 were referred; in Materia Medica, of 258 candidates 178 passed and 80 were referred; in Practical Pharmacy, of 226 candidates 181 passed and 45 were referred. The Examiners in Chemistry, Materia Medica, and Practical Pharmacy are elected by the Royal College of Physicians of London.

The Examiners in Anatomy and Physiology for Second Examination are appointed in conjunction with the Royal College of Physicians; they have conducted the Primary Examination under the old regulations as well as the Second Examination by the Examining Board in England; 811 candidates presented themselves for examination in Anatomy, of whom 443 passed and 378 were referred; 803 candidates presented themselves in Physiology, 454 of whom passed and 349 were referred. The fees paid by candidates for these examinations amounted to £3,726 9s., the examiners receiving £1,825 2s.

The Board of Examiners in Anatomy and Physiology for the Diploma of Fellow, elected annually by the Council, held two meetings for the examination of 171 candidates, of whom only 63 passed while 108 were referred. The fees received amounted to £1,050, of which the Board received £284.

The Court of Examiners, ten in number, are elected by the Council from the Fellows of the Council only for a period of five years. They conduct the Third or Final Examination in Surgery of the Examining Board in England, as well as the Second or Final Examination for the diploma of Fellow. During the past collegiate year the Court has held two examinations for the Fellowship and four for the Membership; at the former there were 79 candidates, 45 of whom passed, 4 were referred for one year, and 30 for six months. For the Membership, 937 candidates presented themselves in Surgery, of whom 579 passed and 378 were referred. The fees paid by candidates for these examinations amounted to £10,142 3s., and the fees paid to the Court of Examiners and the Examiners in Midwifery amounted to £5,097 13s. The Examiners in Medicine under the Scheme are elected by the Royal College of Physicians of London. Of 905 candidates examined, 521 passed and 384 were referred. The Examiners in Midwifery are appointed in conjunction with the Royal College of Physicians of London, and have examined 824 candidates, of whom 558 passed and 266 were referred.

The Board of Examiners in Dental Surgery have held two meetings for the examination of 121 candidates, 84 of whom received the diploma and 37 were referred. The fees paid by candidates amounted to £582, the Board receiving £312 8s.

The Examiners in Public Health, appointed in conjunction

with the Royal College of Physicians of London, have examined 53 candidates in Part I, 35 of whom passed and 18 were referred. In Part II 46 candidates presented themselves; 26 received the diploma and 20 were referred. The fees received for both Parts amounted to £234 12s. 6d., the examiners receiving £186.

With regard to the finances of the College, it appears that the income from all sources amounted to £28,490 8s., the largest receipt being derived from the fees paid by candidates for the diplomas of the College, namely, £18,791 15s. 9d., the next largest item being from dividends on the Erasmus Wilson bequest, £4,813 16s. 1d.; rents from chambers adjoining the College produced £750; investments, £750 2s. 8d.; hire of rooms, sale of questions, at Examination Hall, £680 17s. 3d.; fees retained for referred candidates, £334; from trust funds, £275 9s. 2d.; incidental receipts, sale of calendars, etc., £14 1s.; from sinking fund, £2 5s. 11d.; Goldsmiths' Company Research Grant, £500; balance at bankers 1894, £1,578 2s.

The expenses for the year amount to £27,760 11s. 3d. (leaving a balance at bankers of £729 16s. 9d.), the largest item being for fees to examiners, £8,840 8s.; expenses of examinations (Fellowship and Dental only), £342 7s. 1d.; half expenses Examination Hall, £4,519 9s. 5d.; half expenses research laboratories, £825 18s. 11d.; rates, taxes, and insurance, £1,540 12s. 10d.; extraordinary expenses, £298 1s. 10d.; alterations and repairs, £669 5s. 8d.; fees to Council, £240 9s.; salaries, wages, and pensions in the three departments (Museum, Library, and College), £4,693 6s. 2d.; lectures, catalogues, specimens, etc., for Museum, £673 11s. 9d.; purchase of books, etc., for Library, £653 9s. 4d.; trust funds, £302 3s. 10d.; fees returned to candidates, £556 10s.; purchase of stock, £2,150 15s. 7d.; expenses Metropolitan Asylums Board (repayable), £186 5s. 9d.; miscellaneous items, that is, fuel, light, printing, stationery, etc., £1,267 17s. 11d.

From the librarian's report it appears that the supply of new books has been well kept up during the past year. The donations include the manuscript material for a Greek medical lexicon prepared by the late Dr. Greenhill, presented by Miss Greenhill; a collection of pamphlets from Sir Henry Acland; several old books from Mr. Alfred Kisch; and a manuscript report of John Hunter's lectures from Mr. C. Leeson Prince. The copper and steel plates used for printing Mr. Joseph Swan's book on the nervous system have been presented by Mrs. J. V. Machin, of Gateford Hill, Worksop. Exchanges have been made with the British Medical Association and the Medical Society of Victoria. Amongst the old books purchased may be mentioned a copy of the rare (1672) *Treatise of Wounds*, by Richard Wiseman. The collection of portraits has received a valuable addition from Mr. James Hogg in the shape of a series of daguerreotypes of eminent physicians and surgeons taken by him nearly fifty years ago. Mr. Hogg has also presented a portrait in oil of a surgeon (name unknown), dated 1677, and several volumes of interesting pamphlets. Including journals and transactions, the total number of volumes in the library is about 48,000.

Amongst the additions to the Museum may be mentioned a sarcoma of the patella; a roll of hair weighing 5 lbs. successfully removed by operation from the stomach; an enlarged spleen in a child which weighed one-sixth of the whole body weight. Mr. Willoughby presented a humerus taken from an Egyptian skeleton dated about 4000 B.C., and, in addition to its antiquity, is of interest as showing an old injury to the head of the bone, which must have produced considerable deformity of the limb. An important addition to the Museum is that of 205 skulls and crania with 40 models purchased from the Anthropological Society.

The Secretary's report contains an abstract of the work done by the Council and Committee; the Committee of Management of the two Royal Colleges; the research laboratories on Victoria Embankment; reports of meetings of Fellows and Members; results of elections, etc.

THE CHOLERA.—According to the returns issued on the present state of cholera in Russia, there occurred during the last fortnight of September in the province of Podolia 51 cases and 19 deaths from the disease, and in the province of Volhynia 7,827 cases and 3,086 deaths.

THE PRISONS COMMITTEE.

NOTES ON THE EVIDENCE AND REPORT.

ADMINISTRATION.

Nothing comes out more clearly in the recently-issued Blue Book of evidence taken by the Departmental Committee on Prisons than the failure of certain noisy and neurotic critics to prove their charges of maladministration against the prison authorities. With everything in their favour in the way of a sympathetic tribunal, whose members were practically ignorant of prison management, they have nevertheless signally failed to establish this part of their case. Whatever the defects of our "Prison System" may be, it has been abundantly shown that this system rests entirely on Acts of Parliament which have been passed for the guidance of prison authorities, and the evidence from beginning to end proves that the Commissioners of Prisons have administered these Acts with loyalty and fidelity, and that the transfer of the prisons to Government has been to the public advantage in the way of economy, uniformity of discipline, and improved sanitation, while it has distinctly tended at the same time to the advantage of prisoners themselves.

All this is somewhat grudgingly admitted by the Committee, but it is not easy to see from the evidence how any different conclusions could be arrived at. The direct gains to the community in economy and improved sanitation, as reflected in the reduced death rate, would of themselves have sufficiently justified the changes made in 1877. On this subject the testimony of Sir Godfrey Lushington, after his long experience at the Home Office as Under-Secretary of State, is very valuable. Question 11,539. "I consider the transfer has been eminently beneficial, and not merely as a cause of the better administration of the law, but as much more humane towards prisoners. The immediate purposes of the transfer, which were economy and uniformity, have been entirely fulfilled, and I believe individual abuses are now reduced to a minimum, and all the provisions of the Act are most carefully carried out."

Almost all the other witnesses who were examined, as well as the Committee themselves, agree in this opinion.

INSANITY IN PRISONS.

Some very disquieting statements had appeared in the public press on this subject. It had been openly alleged that prison treatment was producing insanity, and the Committee had before them some figures to prove that this was the case, and further that a higher ratio of insanity prevails in prisons at present than in former days when prisons were under local control. A cursory examination of these statistics, however, showed them to be so unreliable as to carry with them their own refutation. It was seen at once, by the very explicit tables of insanity furnished by the medical officers of the local prisons in the reports of the Prison Commissioners, that the statistics put forward included not only prisoners who were specially remarked for the purpose of ascertaining their mental state, but also many others who were undoubtedly insane on reception. These formed by far the largest proportion of the whole number. Thus for the year ending March 31st, 1894 the total number of insanity cases in the prisons of England and Wales was 342. Of these 342 were either insane on admission or within a month, while 42 only became insane a month, or more than a month, afterwards.

The residue left, after weeding out these people who drifted into prison because they were insane, still appears somewhat large for a prison population of 14,000 when compared with the general population; but all the expert evidence given by Drs. Glover, Shaw, Nicolson, and Lewis went to show that prisoners are (as Sir E. Da Cune put it) "mentally, morally, and physically below the average of the general population," and therefore likely to yield a higher ratio of insanity. It would be absurd to expect that criminals, who are taken from the most drunken and dissolute class of the lowest ranks of society, should exhibit an average degree of mental stability. Alcoholism is a large factor in the production of insanity as well as of crime, and every prison surgeon knows that the mental injuries of violence which abound amongst prisoners are a fruitful source of epilepsy, and of

much of that mental instability which characterises the violent criminal class.

For these and other reasons the insanity cases which arise in prisons must of necessity exceed those in the general population of corresponding ages. In a special memorandum on this subject appended to the report of the Committee, Dr. Bridges, one of the members, estimates the proportion as 3 to 1. Whether or not this result be correct, it is clear that his calculation does not rest on a sound statistical basis, for he compares the daily average population of the local prisons—which is roughly 14,000—with the general population. As, however, the total number of prisoners received in the year under review amounts to 184,000, it is obvious that the prison population changed thirteen times in the course of the year, and no such change as this can be said to take place in the general population.

That imprisonment *per se* should be productive of insanity in any but exceptional cases is totally opposed to the experience of prison medical officers. All the prison officials who were examined on the question were in full agreement about it. The theory undoubtedly has a certain amount of *a priori* plausibility, but it fails to take account of the personal and mental peculiarities of the criminal class, as well as of their surroundings. The lunacy experts, Dr. Shaw of Barnwood and Dr. Lewis of Wakefield, whose experience has brought them in contact mainly with prisoners who have been certified insane, gave it as their opinion that prison life tended to develop, though it might not actually give rise to, insanity. It seems just as likely that the present humane system of imprisonment, with its regularity of living and enforced abstinence from drink, preserves rather than impairs the faculties of such an intemperate and mentally unstable class as criminals are admitted to be.

WEAK-MINDED PRISONERS.

This class constitutes from 2 to 3 per cent. of the prison population. It embraces all shapes of mental deficiency, congenital and acquired. Epilepsy, sunstroke, cranial injuries, and alcoholism, appear to be the commonest causes of the acquired variety. They are a most difficult class to deal with in prison, as they are not amenable to ordinary discipline, and exhibit varying degrees of irresponsibility. They are for the most part habitual offenders with short sentences, and, as they are constantly returning, prison is the nearest approach to a fixed address they can be said to possess. Further, they are found to some extent in all prisons, but more especially in the populous centres, so that there are considerable difficulties in dealing with them as the Committee suggest, by concentration. An attempt was made in this direction a few years ago by the Prison Commissioners, who selected certain district prisons to which such cases could be transferred, but owing to the shortness of sentences and other causes it was found to be impracticable. The care and management of these prisoners, however, have not escaped the attention of the Commissioners (which, by the way, the report of the Committee would seem to imply) for on page 579 of the book of evidence there is given the standing order No. 134, dated February, 1885, directing that such cases should be associated in rooms under the personal supervision of special officers, and under medical care.

Judging by the questions put by Mr. De Rutzen, the police magistrate, to various witnesses as to how weak-minded offenders should be dealt with, it would appear that this class is quite as great a source of embarrassment to magistrates as it is to prison managers. A place of detention, at least for the long-sentence portion of them, intermediate between a prison and an asylum, and in which perhaps inebriates might be treated also, is suggested as the best device for dealing with these mental incurables.

REHABILITATION.

In view of the finding of the Committee that there is "a real and substantial decrease of crime," undue importance seems to have been given to the increased numbers of repeated convictions. The evidence of Sir E. Da Cune and of Mr. Troup shows this increase to be partly due to an improved system of identification; but a still more general cause would appear to be the short-sentence system at present in vogue. Habitual criminals, who now receive sentences

of one year instead of five or seven as formerly, are much oftener at large, and have many more opportunities, so to speak, of getting convicted.

The growth of recidivism, therefore, is in this way quite consistent with a decrease of criminals and crime. The Committee say "the head springs of recidivism are to be found in the social conditions of the general population," and base this theory on an anecdote told to them by Mr. Davitt (*Report*, p. 11), but it seems improbable that a general cause of this kind should produce so comparatively few results, for habitual offenders are but a small class in proportion to the general population.

A very hopeless view of their reformation was taken by almost every official who was examined, and who had had experience in dealing with them. Many of them exhibit mental defects which make it difficult for medical officers to gauge their responsibility for prison offences, and their fitness or otherwise for punishment. The community, however, has a right to be protected from them, and long periods of detention, such as the Committee recommend, are the only means at all likely either to reclaim these offenders, or to give adequate protection to the public.

CLASSIFICATION.

The Committee lay great stress on a better system of classification. That which they recommend, however, is so complicated that it is likely, to prove unworkable in practice. At present each prison is in itself a microcosm, in which the separate cell system enables the governor to classify all his prisoners as he likes and keep them apart. If, however, distinct prisons, or parts of prisons, are to be reserved specially in future for each class, such as juveniles, first offenders, young prisoners, habitual criminals, inebriates, etc., many of whom have but short sentences to undergo, it is obvious that several prisoners will be kept travelling up and down the country, at an enormous cost to the public, denuding prisons of officers required for escort duty, and with no corresponding advantages to themselves or to society. The sole object of this classification is the reformation of the criminal; but imprisonment has other aims in view. A law breaker, under existing Acts of Parliament, is supposed, in the first place, to be punished for his offence. In undergoing this punishment he is placed under very favourable conditions for reforming his vicious courses, and by means of the mark system and enforced industry he helps to work out his own reformation. The Committee propose to change all this, and subordinate the penal to the reformatory part of prison treatment. We have before us, in the New York *Emira*, an object lesson in an institution conducted on these lines, which, to say the least, is not encouraging; it is said to be "the laughing stock of Europe."

Whether we should follow this American experiment and convert our prisons into reformatories seems to most people very doubtful policy. Statistics which were laid before this Committee bearing on the deterrent effect of our present prison system showed that "of every 100 who go to prison a first time 70 do not return again." We know then that not only is crime steadily decreasing, but that our prison treatment is exerting a powerful deterrent effect at all events on first offenders, and probably on great numbers of potential criminals besides, who keep clear of the clutches of the law, while it fails to reclaim habitual offenders. If, however, everything in prison treatment is to be sacrificed to the one object of reformation, we must run a serious risk of impairing the deterrent features of the system for the very doubtful chance of reforming habitual criminals, a class who are least susceptible to moral influences, and who are at the same time those who will gain most in prison comfort from the relaxation of penal discipline. Such privileges as "talking," "gymnastic exercises," and "technical instruction," as recommended, even out of place in a penal establishment. By all means abolish non-productive labour, which was almost unanimously condemned by witnesses as useless and demoralising. Give prisoners more exercise to maintain their health, and cultivate as far as possible the *mens sana in corpore sano*, but to return to the principle of association after the experience of the past is a retrograde proceeding fraught with the special evils which John Howard spent his life in trying to reform.

OPENING OF THE WINTER SESSION IN THE MEDICAL SCHOOLS.

LONDON HOSPITAL.

PRESENTATION OF TESTIMONIAL TO DR. HUGHLINGS JACKSON,
F.R.S., BY SIR JAMES PAGET.

THE Library of the Medical College of the London Hospital was on October 1st the scene of an interesting ceremony, the occasion being the presentation to Dr. Hughlings Jackson of his portrait in oils, painted by Mr. Lance Calkin, and a piece of silver plate in the form of an antique silver ewer, subscribed for by his colleagues on the staff and other friends, and bearing the inscription that it was presented "in recognition of their esteem and admiration of his great services to the London Hospital and Medical College, his distinguished position in the profession, and of the advances he has effected in medical science by his laborious investigations and profound insight into diseases of the nervous system." Sir JAMES PAGET, F.R.S., D.C.L., occupied the chair, and was supported by Sir William Broadbent, Sir Spencer Wells, Professor Burdon Sanderson, Dr. Buzzard, Dr. Savage, and many members of the medical and surgical staff of the hospital.

Mr. HALE (Chairman of the House Committee) opened the proceedings, and requested Sir James Paget to present the portrait and plate, alluding in his speech to Dr. Hughlings Jackson's long connection with the hospital, and his high position in the profession.

Sir JAMES PAGET, in presenting Dr. Hughlings Jackson with his portrait and a silver ewer, said: The only possible ground upon which I can accept the honour offered to me in presenting this testimonial to you is that once you were a pupil of mine, attended my lectures, and helped me in my practice. As far as I know, I am the only one now surviving who can claim that honour. That honour I do claim, and it is some consolation to claim it when one has passed the power of active work in the sciences of our profession, and can therefore only look back to the happiness of seeing the work of those whom one in some degree, however small, promoted in their work by one's teaching. I remember you well more than thirty years ago. You sat regularly at my lectures; you were one of those attentive and watchful students who make lecturers careful, and compel them as far as possible to keep their work up to a level which shall be better than that of their pupils and yet intelligible to them. I well remember you to have been a constant help and guide and promoter of one's own best work. It may seem rather strange to claim an honour from one's pupils in the honour which they receive; but it is a consolation to think that to-day when as one grows old one finds one's pupils going so much beyond one's own knowledge than ever one's own knowledge was beyond theirs; and that is remarkably the case when I compare what I could now tell with what Dr. Hughlings Jackson has told you. I wish I could express half the good feelings that have been said or written by those who have contributed to this testimonial. Let me only assure you that the words that are inscribed upon it do tell us as nearly as possible that to which all have consented; they seem to rival one another in their expressions of esteem and gratitude for the work you have done. Among them are the leading men of science and of sciences, some of them beyond the ordinary range of medicine. There are the pupils, old pupils, colleagues all the leading men who have done best work in medicine and surgery, and all have concurred in this. Let me beg you to receive these testimonials, and believe that with them there comes an expression of our heartiest wish that you may yet live long in health and happiness, and especially may enjoy that supreme happiness of doing good in the promotion of the length of the life of men and in your capacity for work. This you have done all your life long thus far; may you be able to do it yet for many years to come; and when you reach the time that I have reached, and find that you can no longer go on with such active work, then may you have the happiness, as you surely will, of remembering the good that you have done in the more indirect manner, by the pupils you have had who are still doing good work, and following your good example. In presenting this portrait to you allow me to say that I believe

others will look upon it with more pleasure than you will yourself, for it tells you that you have the appearance of a remarkably distinguished man.

Dr. HUGHLINGS JACKSON, in replying, said that words were unable to express how deeply he felt the kindness shown to him, and the honour was very much enhanced by the fact that the presentation had been made by Sir James Paget. He rejoiced to have the opportunity of declaring how much he had been indebted to Sir James, not only for scientific aid, but also by a bright example of uprightness of conduct. He (Dr. Jackson) had been connected with the London Hospital for more than thirty years, and a great part of those researches of his of which good-natured people spoke so kindly were begun in the out-patients' room. He advised both his colleagues and the students to cultivate that department of the hospital. During his connection with the hospital he had made many friends, and it was not possible, he thought, for any man to have had pleasanter colleagues than he had had. He thanked Mr. Caikin for the great patience and skill with which he had painted the portraits, and he also felt highly gratified in seeing around him so many eminent members of the medical profession; but he could not, however long he spoke, say how much he felt the kindness shown to him by all. He could only say that he thanked them most heartily.

Sir JAMES PAGET, in presenting the other portrait of Dr. Hughlings Jackson to Mr. J. H. Buxton, Treasurer of the London Hospital, who received it on behalf of the College, said: Ladies and gentlemen, I have now the happiness of presenting another portrait of Dr. Hughlings Jackson, which is to appear constantly in the College in the sight of all the students and those who visit the school. This will be, I believe, of real value to both school and hospital. There is nothing of the kind that can be better than the seeing from time to time, or even daily, a portrait of those in whose places one stands, or whom one can boast of as having been directly or indirectly one's teacher. At St. Bartholomew's Hospital I know I can never look at the group as they stand of Percival Pott, Abernethy, and Lawrence, without thinking of the good example they may set me; without feeling what a discredit it would be to throw dishonour on the institutions of which those men were such bright ornaments, and the shame it would be if one did not study their works, and try, if not to attain their eminence, to at least follow their example as far one's own power would admit. As it is there, so it will be here with Dr. Hughlings Jackson's portrait in the school. Those who look at it will ask, if they do not already know, What work did he do? How did he gain that distinction? How does his influence come to bear upon me? And they will learn it. Let me take this opportunity of pointing out what, I think, will be its chief lesson. So far as I can judge from the works of Dr. Hughlings Jackson—I never have been able to follow him in all the minuteness and completeness of his work in neurology and diseases of the nervous system—I can see this, which I would hold to be a great lesson for all students of medicine for all time to come, that he has never failed to make science and practice work together. He has always regarded the clinical room, or as he told us even the out-patients' room, to be a place for scientific study as surely as the laboratory, and that the facts to be gained in one may be quite equal with the facts obtained in the other. That is the rule which all students, nay, I will go further and say that is the rule which all practitioners of medicine should carry through life. Whatever they see, whatever they are within reach of, may be a subject of scientific study and bring forth fruit of the greatest value. This is very well known to all those who have studied Dr. Hughlings Jackson's works; but it has struck me as having been a part of that which has determined his career all through his life, that he has constantly believed and sought to find that in every casual fact, as it might seem to others in medical practice, must be tried to be incorporated in the general body of science. I have always recollected an expression made to me by the late Sir Richard Owen—that all the best essays on the great principles of science were written in monographs, the works of men who seem to give themselves to one study exclusively. I have looked at many works in that view, and it is quite true that the best scientific works are in monographs; but then the authors of those

monographs were all men who studied science in its widest range within their minds. They did apply their studies especially to one principal subject, but their power of interpretation was due to their having studied science everywhere within their reach. Sir Richard Owen himself was often an example of this, and many others also could be quoted. Dr. Hughlings Jackson, it may be said, has studied only diseases of the nervous system. He has been a writer of monographs. He has been, some would say with a sneer, a specialist. Well, he has studied one range of subjects especially, but in all of it he has had in view that this is but one small element in the whole body of knowledge. I was struck with this when I looked at one of his earliest works which was printed for private use—I do not know whether it was ever published—in which he had in mind that the pathology of the nervous system might be brought into order by adopting the plan of what he called "Owen's vertebrate theory." Whether it was so or not, I will not venture to say, but as I have read that pamphlet I have seen the resolution all through: "I am observing this and that every day of my life; my object will be to bring this and that into concord with other branches of science, and into order, as evidences of one large, general rule." If I might refer to one work by which his name is best known, I would quote it as an example—Hughlings Jackson's *Epilepsy*. It has for years remained, and for years to come it will remain, a distinctive feature. But its full value is shown in that resolution that nothing should pass him unobserved or unthought of. The principal phenomenon of Hughlings Jackson's *Epilepsy* is one that many men saw before him, and perhaps thought of it; but the greater part of them, and those of his own time too, looked upon it, and were satisfied with those comfortable words: "it is a very curious thing." So they would tell of it day after day, month after month; they would tell of it that it was a very curious thing; and after that they were satisfied. But Dr. Hughlings Jackson worked it out, and found it again and again in all its various forms, and out of that he helped to establish one of the greatest rules of modern cerebral pathology. Out of that, as a beginning, working with general rules, he helped more than any man I can name to determine cerebral localisation; he has helped to bring in the whole mass of cerebral surgery, to say nothing of the help he has given on the medical side. I will repeat again that this is what all students in all times may keep in mind. If they are to make medicine advance they must not do it by studying one narrow piece of work unless they have studied it with the broadest knowledge of science previously attained. This then I trust will be the good of the portrait which is to be presented to the medical school and College. It will be seen by all, and all the good that Dr. Hughlings Jackson has already done will be maintained, possibly even multiplied, by the good example which they will see in the portrait.

Mr. J. H. BUXTON and Dr. STEPHEN MACKENZIE acknowledged the gift.

The students' prizes and certificates were then presented by Sir James Paget; and Mrs. Hale distributed the prizes and certificates to the probationers.

Sir JAMES PAGET again addressed the meeting. He said: I have yet a few words which I am expected to add. My first duty is to congratulate those to whom certificates and prizes have been given. For the students of the hospital I may say that I hope this will be to many of them as much the beginning of a prosperous career as I can boast it was of my own, for I well remember as a student the great advantage I gained by being assured that up to the time of receiving my prizes I had done my work carefully and thoroughly as far as I then could. Whatever may be the respective merits of those who have and who have not received prizes now, I can for certain say that those who have received them may be marked as men who have done their best; and in doing their best they have shown themselves fitted for the future part of their life; they have shown that they have that property upon which success depends more than anything else I can name, the property of loving to work. When I look back on all I have known in the profession I should say that the one element of success before all—I mean for real, substantial, and praiseworthy success—has been the power of work.

I will give just one piece of advice, and that is that no student, whether he has been thus far successful or not, should be anxious to put a willing measure to the quantity and kind of work that he can do. There is a common expression used by students, and even by grown up and old men, "I will if I can." I have often said that it would be better to reverse the expression and say "I can if I will." If a man will go on in life saying "I will do this, I will do that," he may not achieve the whole of his intention but he will achieve a great deal. The students who have been successful thus far by continuing that plan will add to the renown of this great hospital a renown as high as can be said for any hospital in the world. Then also let me congratulate those who have received as probationers their prizes and certificates. It is an entirely new thing for me to have to address nurses on an occasion such as this, but it is a very happy one, for I know nothing of which I can speak in the history of hospitals as having become more prosperous or gained greater advance than in the cultivation of the true art, and skill, and science of nursing—the true science of nursing we shall very soon have to call it. As I look back upon the nursing of old times—well, the nurses were all women, and, therefore, they were more gentle, and more considerate, and more sympathising than men would have been. Many of them were remarkably good, and even skillful, nurses. Many of them were old women—I do not remember that there were any "new women" among them. Even now the work that they do is rising every year in importance and in utility. I chance to know very well, at least by report, the good work that is done thus in teaching in the London Hospital. I have the privilege of knowing Miss Paget, who has worked here for many years, and who, I am sorry to say, is no relation of mine. I have heard from her account that the teaching of the London Hospital is as thorough and complete as it can well at present be made. So that I may well congratulate all those upon having done their best in the very good work whether as students or as nurses. And here I may venture to say that I may speak of that as an advantage, not only to themselves and our profession, but to the hospitals. To-day is what we might call New Year's Day, for all hospitals and medical schools have now begun again the work of the new year. We are all collected together, and now we enter upon another year of active competition in which all the staff of every hospital is expected and bound to do its very best. It is out of this competition amongst skilled and honest persons that the greatest good can come. I venture to say that there is nothing more complete for what a hospital should be and do than is thus established in our English hospitals, where we have schools connected with the hospital, dependent upon its reputation, and ready to judge all that they see going on. Every member of the medical staff in the London Hospital carries on his whole career under a very strict discipline of examination by those around him. There is complete publicity in the work of a great hospital, students are ready not only to see but to judge. I venture to say that no Government superintendence of whatever kind, no superintendence of a hospital carried out in any part abroad can match the value of the oversight of students well educated and well trained to observe. So that I would not even speak of the promotion of the advantage of a school as if it were concerned with the school alone, and the hospital had nothing to do with it; I would rather say that the governors of the hospital cannot do better than spend money—as far as they may have it—on the promotion of the school, as well as the more direct purpose of the hospital. Every improvement of the school is at once an improvement of the work done in the hospital; every promotion, therefore, of medical learning is a promotion of charity. The working of the two things together—science and charity—have had their very best result, the best result that can be obtained in this kingdom. This is what is continually going on in all our London hospitals. It is not as if they were to study mere science, and carry out their knowledge somewhere else; they study it, and at the same time they make themselves more fit for the study of medicine. The hospital, therefore, becomes not merely a centre for good work, but a centre from which springs true work and true charity done in all parts of the kingdom—nay, wherever in the world

members of the profession may be. Never let it be thought or repeated that the benefit of the hospital is solely in direct charity to the patients; the benefit is by offering the best possible opportunity for the study of medicine, the promotion of it, and the carrying it to distant parts. This I know, is accomplished in the London Hospital; this is accomplished, indeed, I believe, in nearly all the hospitals which now begin their work. So that, as I have called this a new year, I do not think I can better end this meeting, which has been to me a source of greatest pleasure and happiness, than by wishing all present, especially this school and this hospital, a very happy and prosperous new year.

On the motion of Dr. SAMUEL FENWICK, seconded by Mr. FREDERICK TREVES, a hearty vote of thanks was accorded to Sir James Paget; and a vote of thanks was also passed to Mrs. Hale.

ST. BARTHOLOMEW'S HOSPITAL.

A most successful evening was spent on October 1st at St. Bartholomew's Hospital, where the Old Students' Dinner was held in the Great Hall of the hospital. About 130 were present, including Mr. Howard Marsh, Lecturer on Surgery and Surgeon to the Hospital, who occupied the chair; Sir James Paget, Sir Trevor Lawrence, Sir George Humphry, Professor Clifford Allbutt, Professor Burdon Sanderson, Dr. Hill, Master of Downing College, Cambridge; the Dean of Christ Church, Oxford; Sir Horace Walpole, Mr. Hanbury, Mr. Trimmer, Mr. Hallett, Captain Percival, Dr. Rutherford, of the Westminster School; Mr. Thomas Smith, Senior Surgeon; Dr. Church, Senior Physician; and most of the staff of the hospital and school. After an excellent dinner, the chairman proposed the loyal toasts of "The Queen" and "The Prince of Wales, Princess of Wales, and Royal Family." These having been duly honoured, he next proposed the toast of the evening, "Prosperity to St. Bartholomew's Hospital and School." In the course of his remarks Mr. Marsh referred to the great antiquity of the hospital and its foundation, and to the historical and other associations of Smithfield, and the Priory and Hospital of St. Bartholomew. He spoke in well-chosen words of the unity of the hospital and school, which he said was largely due to the influence of the present treasurer, Sir Trevor Lawrence. In regard to the medical school, he spoke of its continued success. The number of teachers is continually increasing; now there are over 60 teachers. The Jacksonian Prize, which has so many times been won by St. Bartholomew's men, was this year awarded to the Senior Demonstrator of Anatomy, Mr. Waring. He spoke of the social organisation in connection with the medical school, and the good feeling existing between staff and students. During the past year the Rahere Lodge of Freemasons has been initiated in connection with the hospital and the Students' Club Ground with its handsome pavilion, opened. The toast was enthusiastically received. Sir James Paget then proposed "The Visitors," and his son, the Dean of Christ Church, responded. Sir George Humphry proposed "The Chairman," and Mr. Marsh replied. Mr. Marsh then proposed the health of Dr. Hensley, secretary for the October dinner. He responded and referred to the recent appointment of Dr. Branton as physician, and Dr. Herringham and Dr. Tooth as assistant physicians, and concluded by proposing the health of Captain Hinde, who replied.

No important additions have been made to the school buildings during the past year, but minor improvements have been added to the dissecting room and pathological and physiological departments. In the hospital the surgical equipments have been improved by the opening of the new operating theatre, fitted with all the most modern appliances. The number of available beds has been increased, and their distribution rearranged in connection with the appointment of Dr. Lauder Branton as the fifth physician. For the use of patients four elegant and picturesque shelters have been erected in the hospital quadrangle. From the students' point of view, the most important addition during the past year has been the opening of the new recreation ground at Winchmore Hill, with the handsome pavilion at a cost of several thousand pounds. This ground gives accommodation for the football, cricket, and tennis clubs, and the pavilion consists of a large common room, with three dress-

ing rooms, besides locker room and offices for supply of refreshments.

CHARING CROSS HOSPITAL.

At Charing Cross Hospital the session was commenced without any inaugural lecture or ceremonial function of any sort. The annual dinner of past and present students will take place at the Holborn Restaurant on October 23rd, when Mr. C. J. Woollett, F.R.C.S., will be in the chair.

ST. GEORGE'S HOSPITAL.

The introductory address was delivered at 4 o'clock by Mr. George D. Pollock (Consulting Surgeon to the Hospital) in the large theatre, which was decorated with palms and ferns for the occasion. In the evening the annual dinner was held in the Whitehall Rooms of the Hôtel Métropole, under Dr. Blandford's presidency. Upwards of 130 guests sat down, including the Treasurer of the hospital (Mr. T. Holmes), Admiral Sir Houston Stewart, Dr. Dickinson, Mr. Pollock, Dr. Duka, Dr. Patrick Manson, the members of the hospital and school staffs, and other distinguished past students. The toast of "The Governors of the Hospital," proposed by Dr. Dickinson, was acknowledged by Mr. Holmes. In reply to the toast of "The St. George's School," proposed by the Chairman, the Dean (Dr. Isambard Owen) alluded particularly to the progressive increase in the number of its students and to the establishment in the school, for the first time in London of a Lectureship in Tropical Medicine—a step taken in pursuance of representations made in these columns. The "Orator of the Day" was proposed by Mr. Whipham and responded to by Mr. Pollock. Dr. Collins, of New Zealand, now on a visit to England, replied to the toast of "The Past Students," proposed by Mr. Pick, the "Present Students" being represented by the Senior House-Physician (Dr. Wilson), lately a Radcliffe travelling Fellow of the University of Oxford. A musical sketch by Mr. Mercer Adam concluded the proceedings, which were marked throughout by much enthusiasm.

The whole of the interior of the hospital has been repainted and decorated, and an extensive reconstruction of the central block, not visible from the exterior, has been undertaken and carried nearly to completion. The reconstruction will provide an ample nurses' dining room, an enlargement of the Boardroom and chapel, and two entire new operating theatres. The theatres and their accompanying lavatories and anæsthetising rooms will be of the most modern construction, the floors and benches being executed in white marble *terrazzo*, the walls impermeable, and the internal fittings entirely of metal and glass. The chapel, which originally formed part of Wilkins's design, is being rebuilt in Middle-Gothic style. In the schools, in addition to painters' work, the corridors have been lighted with electricity; the arc light has been laid on to the theatres for lantern demonstrations; the anatomical collection has been extended, and a separate collection of surgical instruments supplied for inspection by students.

GUY'S HOSPITAL.

The inaugural proceedings of the new session were left, as is the custom, in the hands of the Physical Society. Dinner, at which a large company of the staff and past and present students were present, was served in the College Hall at 6 p.m. Dr. Pye-Smith, as President of the Students' Club, occupied the chair, and was supported by the Treasurer of the hospital (Mr. E. H. Lushington), Drs. Samuel Wilks, Frederick Taylor, Goodhart, Savage, Perry Newton Pitt Campbell, Starling, Stevens, Messrs. Davies-Colley, Brailley, Symonds, Dunn, Groves, Targett, Hopkins, and Bellingham Smith. After dinner the company adjourned to the Anatomical Theatre, where a packed audience was assembled. The chair was taken by Dr. Samuel Wilks, F.R.S., and, before commencing the ordinary business of the meeting, an interesting ceremony was gone through—the presentation to Mr. H. C. Regnart, a student, of a Royal Humane Society certificate for saving five lives off Alderburgh. In making the presentation, Dr. Pye-Smith said he had been entrusted with the great honour of presenting to one of their number the certificate awarded by the Royal Humane Society for courage and self-sacrifice in saving or endeavouring to save life. On this occasion the endeavour was successful. It was but seldom that such an

opportunity could fall to anyone, but all might pray that, should it happen, they might discharge their duty as well as Mr. Regnart did. This was not quite an occasion without precedent, for in the year when he (Dr. Pye-Smith) entered as a first year's man, one of his fellow students, a Mr. Phillips, gained a similar award. It was in the hospital chapel that a great divine, the late Frederick Denison Maurice, once the Chaplain of Guy's, preached a sermon which he did not hear. The fault was one of chronology. He was then at a preparatory school. It was told him by Sir William Gull that Maurice then said: "There are two ways to greatness—sympathy and courage." In their profession they had need of both. Might they all have that sympathy which was necessary in dealing with their suffering fellow creatures, and might they all, if occasion should arise, have the courage to follow Mr. Regnart's example. The certificate having been presented amid a demonstration of approval, Dr. Samuel Wilks, as President of the Physical Society, proceeded to offer a few words of welcome to the new comers. He congratulated them on their choice of a profession which, above all others, could be followed in its various branches with the most intense interest during the whole of their lives. He might instance his colleague, Dr. Pavy, whom they found still devoting himself to study, and at the end of a long career finding material to add to the knowledge of his subject. They would be taught much during their hospital course, but one thing they would not learn—namely, that there were diseases having particular names and particular remedies for them. That was not science, but quackery, and he warned them against the quackery and chicanery which existed on so great a scale. Scientific truth none could withstand, so that it was a sure sign of the worthlessness of a system if it existed for a hundred years without being absorbed into the body of general knowledge. When he entered the profession he felt pessimistic at the evils which abounded, but now at the end of his career he could sincerely tell them to be hopeful. Let them pursue a straightforward path, and they might depend upon coming out right in the end. But let them remember that having entered the portals of the profession they were no longer free men; they had a duty to the profession, and what was true of the profession was true also of the particular school at which they had entered. They were Guy's men, members of an institution with a glorious past. He and the men of his generation were going off the scene; they had to leave the place in the hands of those to whom he spoke, and to them they looked to keep up the old and great traditions of Guy's Hospital. He called upon Mr. George De'Ath (Buckingham) to read his paper, which is published at page 830, Mr. De'Ath receiving an enthusiastic vote of thanks for his paper. The Treasurer of the hospital, in acknowledging a similar compliment, spoke of the death of Mr. Arthur Durham. He rejoiced that Guy's men had so liberally responded to the proposal that two beds should be endowed in the memory of their old friend. The cost of the two beds would be £2,000, and he was able to announce that the whole of the money had been found. Mr. Lockhart Stephens, in proposing a vote of thanks to Dr. Wilks, said that in view of the present state of the hospital finances he felt that old Guy's men should not lose that opportunity of doing what they could for the hospital. They had approached Dr. Wilks, and he would take the chairmanship of a committee which had been formed among old students that evening, and as the result of their efforts they hoped to offer a very substantial tribute to the finances of the hospital. Mr. Every-Clayton followed on similar lines on behalf of present students, and a warm vote of thanks having been passed to Dr. Wilks, the meeting was brought to a conclusion.

KING'S COLLEGE HOSPITAL.

The opening of the winter session was marked at King's College Hospital by the annual dinner of old students, held at Limmer's Hotel on October 1st; Dr. K. Shingleton Smith, of Bristol, occupied the chair. The popularity of these annual dinners was shown by the large number who attended, and by the great distances travelled by many medical men in order to be present; some had come from Yorkshire, from Exeter, Bristol, Birmingham, and Tredegar. In proposing success to King's College Hospital and its Medical School,

the Chairman referred to the recent honours conferred upon former students, mentioning, amongst others, Mr. Christopher Heath, who has been elected President of the Royal College of Surgeons; Dr. Brodie, lately elected Lecturer on Physiology at St. Thomas's; and Sir Joseph Lister, who has been nominated President of the British Association for the ensuing year. In lighter vein he spoke of the general recognition of King's as the "home of medicine," since at the annual meeting the British Medical Association had insisted on all visitors to town being received there first. After reminiscences of his student days, Dr. Shingleton Smith spoke of the success attending the new venture, the hospital reports, which already included subscribers from India, China, Australia, and Hawaii. Deputy-Surgeon-General Jessop responded to the toast of "The Army, Navy, and Reserved Forces"; and other speakers were the Rev. Dr. Wace, Chairman of the Hospital Committee; Dr. Lionel Beale; Dr. Alfrey, of St. Leonard's; Mr. Richardson Cross, of Bristol; Dr. Playfair, and Dr. Curnow. Mr. Percy L. Webster and Mr. A. Schartan kindly sang numerous songs during the evening, which were much appreciated.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.

The annual dinner of the past and present students took place at the King's Hall, Holborn Restaurant, on October 1st. Mr. Malcolm Morris in the chair. About 170 sat down. The Chairman, in proposing the toast of the evening, said that a medical school was composed of four elements: the hospital, the school, the staff, and the students, and he gave an amusing sketch of an interview between an old student of thirty years ago and a student of the present day, showing the vast change in the class of men now entering the profession. He said the prosperity of St. Mary's was due in great measure to the energy of the Dean, Mr. Field. The toast was responded to by the Dean. "The Past Students," by Dr. Willis; "The Present," by Mr. A. Thorne; and "The Staff," by Sir William Broadbent, who proposed "The Chairman." Staff-Surgeon T. J. Preston, R.N., replied for "The Navy," Brig-Surgeon Lieutenant-Colonel Myers for "The Army," and Surgeon Lieutenant-Colonel A. T. Norton for "The Reserve Forces." The speeches were followed by a concert, and a most successful dinner was brought to a conclusion. Among those present were Colonel Stanley Bird, the Chairman of the Board; Colonel Blair, R.E.; Mr. Page, Dr. Lums, Dr. Franklin Parsons, Dr. Danford Thomas, Dr. Symes Thompson, Dr. Handfield-Jones, Major White, R.E.; Surgeon-General Jeffcoat, Dr. Waller, F.R.S.; Mr. Critchett, Dr. McCall Anderson, Dr. Sidney Phillips, Dr. Hyslop, Mr. Juler, Dr. Cundell, J.P., Dr. Luff, Mr. John Moore, Dr. Felce, Mr. Lane, etc.

MIDDLESEX HOSPITAL.

At the close of the introductory lecture by Dr. Julius Mickle (an abstract of which is published in another column), the scholarships and prizes awarded during the preceding sessions were distributed by Sir Ralph Thompson, K.C.B., Chairman of the Weekly Board of Governors. The Dean (Dr. Coupland) in his report alluded to the losses sustained by the hospital and school in the past year in the deaths of Sir John Thomas, who was House-Surgeon in 1839-40, and who was the first to hold the office of surgeon-dentist to the hospital. Dr. Goodfellow, the Senior Consulting Physician, who retired from the acting staff in 1872 after twenty-two years' service, and Mr. John Whitaker Hulke, the Senior Surgeon, whose connection with the institution was briefly sketched. Allusion was also made to the death of Mr. Bell Sedgwick, for many years Vice-Chairman, and of the appointment to the Governorship of Bombay of Lord Sandhurst, the Chairman of the Weekly Board. The changes in the staff were next mentioned, and in speaking of the examinations passed by the students the Dean expressed the hope that the University of London question would be speedily settled. The prizes were then distributed, and a cordial vote of thanks passed to the Chairman on the motion of Dr. Cayley, seconded by Dr. Douglas Powell. The numerous company of visitors were then entertained at tea in the Residential College. In the evening there was a large gathering of past and present students and their friends at the annual dinner, which took place at the Cafe Royal, Dr. C. Y. Ross presiding. Amongst those present were Sir E. Thompson, Mr. Kegan Paul, Mr. Jarrett, Mr. Horton, Mr.

Custance, Mr. Nunn, and most of the members of the hospital staff. The toast of "The Services," which was given by Mr. Smith Turner, was responded to by Mr. Lane and Surgeon-Captain G. Cree; that of "The Middlesex Hospital and Medical School," proposed in admirable terms by the Chairman, and most enthusiastically received, was replied to by Sir R. Thompson and Mr. Pearce Gould. "The Past and Present Students" was proposed by Mr. Lane, and acknowledged by Dr. Newman (Windermere) and Mr. Braine Hartnell, the holder of the first Brodrip Scholarship. Then followed the toast of "The Visitors," proposed by Dr. Duncan, and replied to by Mr. Ganz; "The Health of the Chairman" being toasted with *bravo* on the proposal of Dr. Douglas Powell. The success of the gathering was much enhanced by the musical treat afforded, under the guidance of Mr. Wilhelm Ganz, who presided at the pianoforte, by the splendid vocal performances of Signor Giuseppe Maggi, Mr. Bernard Lane, Mr. J. W. Myles, and Mr. W. Irving, the two last named being members of the Musical Society of the hospital.

OWENS COLLEGE, MANCHESTER.

The medical classes of the medical department of Owens College were opened on Tuesday last. The total number of medical students attending the College during the last year was 383. The magnificent new laboratories for physiology and pathology are now completely equipped, and afford every facility both from the point of view of the student and for purposes of research. At the opening of the session, Professor Hickson gave an address on "The Teaching of Zoology." After paying a well-merited eulogy to the influence of Huxley and of Milnes Marshall on the teaching of biology in this country, Professor Hickson pleaded for a more effective recognition of the claims of field zoology. The so-called "types"—perhaps falsely so-called "types"—which the student is called upon to study has its advantages, but it has also its disadvantages. The student requires a broader view. This can only be acquired by a wider acquaintance with systematic zoology, and by practical work in the field. Professor Hickson urged that biology should be taught to boys and girls at school, and that during school time they ought to have opportunity for observation of plants and animals in the open field.

SHEFFIELD SCHOOL OF MEDICINE.

The sixty-eighth session of this school was inaugurated by an address from Professor Victor Horsley, F.R.S. After assuring the students that, provided they had good health and industrious interest in their work, and a liberal proportion of physical exercise and enjoyment, they need have no fear of accomplishing a pass examination, he referred to the large percentage of rejections which actually took place. This he attributed in the main to the fact that the entrance examination was of far too low a standard, especially in the subjects of chemistry and physics. He then passed on to later experiences, and advised every newly-qualified man to act as assistant to a good general practitioner for six months, and hold a hospital appointment. He urged that the British Medical Association and one of the medical defence societies should be joined immediately after qualifying. He then went on to discuss the ethical relations of the profession, and expressed the hope that the energy and activity now being displayed by the British Medical Association would culminate in the passing of a Medical Acts Amendment Bill.

ST. THOMAS'S HOSPITAL.

The prizes for the past year were distributed by Sir Edwin Arnold, K.C.I.E., O.S.I., in the Governors' Hall. The chair was taken by Mr. J. G. Wainwright, treasurer of the hospital. In opening the proceedings he made the announcement that as the result of the recent appeal to the public 60 additional beds would be immediately available for the reception of the sick poor, bringing the number of beds in actual use up to 470. Sir Edwin Arnold gave an eloquent and stirring address, imbued with the true spirit of poetry. He impressed on the students the nobleness of the profession they had chosen, and drew a lofty ideal for them to follow. A vote of thanks to Sir Edwin for his address was proposed by the Dean of the School, and seconded by Sir Henry Donlon. In the evening there was a large gathering of old students

at the annual dinner in the Whitehall Rooms, about 140 being present. Dr. Payne presided. Dr. T. B. Crosby proposed the prosperity of the hospital and medical school, and in doing so feelingly referred to the loss they had all so recently sustained in the death of Dr. Bristowe. The Treasurer responded for the Hospital, the Dean for the Medical School, and Mr. Rice Ord for the Old Students. Dr. William Ord, in a genial speech, proposed the health of the Chairman, Dr. Payne, a toast which was received with great enthusiasm. Mr. Staveley proposed the health of the Honorary Secretaries, Dr. Toller and Mr. Abbott, who may well be congratulated on the complete success of the dinner.

UNIVERSITY COLLEGE, LONDON.

The introductory address was delivered by Dr. J. Rose Bradford, F.R.S., who discussed the position which the preliminary sciences—biology, anatomy, and physiology—occupied in the medical curriculum. While a scientific training was essential to the future practitioner, it was necessary, he said, that the science selected should be one in which the student was able to see for himself practically the data on which deductions were founded. Owing to the long time required to study it properly biology was unsuitable, and the present three months' course was useless as a training. For this purpose human anatomy was to be preferred, since it gave greater facilities for the student to become a careful observer. The value of physiological knowledge to the practitioner was not so great since so much current physiological teaching ignored human physiology in its relation to medicine. The future medical practitioner should receive a more or less specialised course of physiology, differing in certain respects from that suitable to the pure physiologist. No scientific training, however extensive and elaborate, could supplant clinical knowledge and study. Clinical observation could be as sound and scientific a branch of knowledge as any science; it depended upon the capacity of the observer and not on the nature of the subject observed. The annual dinner of the old and present students was held at the Hôtel Métropole on Tuesday, October 1st, under the presidency of Sir Richard Quain. Covers were laid for 120. Among those present were the President of the College of Physicians, the President of the College of Surgeons, Dr. Hare, Dr. George Harley, F.R.S., Dr. Lawford (Leighton Buzzard), Dr. C. Marriott (Reading), and all the present members of the hospital staff. Sir Richard Quain, in proposing the toast of the evening, referred to the opposition which University College had met with in its early days. Those days had passed, and it was gratifying to find that no fewer than thirty-six men who had been educated at University College held important positions in nine of the other medical schools of London, and that University College men were to be found in leading positions in the medical schools of Cambridge, Edinburgh, and Durham. No stronger evidence than this of the continuing success of University College could be desired. The toast was responded to by the Dean of the Medical Faculty, Mr. A. E. Barker. The healths of the Presidents of the College of Physicians and the College of Surgeons, both of them University College men, were proposed by Dr. Poore and Mr. Godlee; and the toasts were welcomed with such applause that Sir John Russell Reynolds remarked in his reply that he had been painfully struck by it—in the drum of his ear. "The Health of the Chairman" was proposed by Dr. H. Charlton Bastian, F.R.S., and suitably acknowledged. During the course of the evening the company were delighted by the excellent singing of Dr. Frederick Roberts, Mr. Sydney Belfrage, and Dr. Walter W. H. Tate.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

The opening ceremony and distribution of prizes took place in the great hall of the College of Medicine, Newcastle-on-Tyne, on October 1st, at 2 P.M., preceded by a reception of visitors and luncheon. The chair was taken by the President (Professor Philipson), who, in the course of his introductory remarks, mentioned that the April convocation of the University of Durham for the conferring of degrees will be held in the College of Medicine, Newcastle, instead of at Durham as heretofore; that the degrees of the University and the classes in the College of Medicine will in future be open to women equally with men; that a Chair of Psychology had been

created during the past year, and Dr. McDowall, of the Northumberland and County Asylum, appointed the Lecturer; that Professor Howden had been appointed Secretary to the College; and finally that a bequest of £200 had been granted to the College by the trustees of the late Professor Johnston, for the purchase of instruments for the physiological laboratories. The prizes and scholarships were then distributed by the Dean of Durham, who was present at the College for the first time and was heartily welcomed. On account of his recent illness the Dean did not give any address. Votes of thanks to the Dean of Durham (Warden of the University), the Mayor and Corporation, and to the President were then proposed and carried. In the evening a most successful dinner of the Durham medical graduates was held, about eighty were present; Dr. Arnison, the senior graduate, occupied the chair.

WESTMINSTER HOSPITAL.

The introductory lecture was given at 4 P.M. by Dr. Monckton Copeman, which was followed by a report from the Dean (Mr. Spencer). Owing to the enforced absence of Viscount Peel the prizes were distributed by Dr. Potter, who concluded with a few happy remarks to the students. The annual dinner of the Westminster Hospital Medical School took place at the Café Monico, on Tuesday, October 1st. The chair was taken by Dr. de Havilland Hall, Physician to the hospital. There were present a number of former students including Surgeon Hugh Macnamara, R.N., and Surgeon-Major Walsh, I.M.S. Most of the members of the staff were, as usual, present, and the House Committee were represented by Mr. G. G. Tremlett, who, with Mr. Spencer, the Dean of the medical school, responded to the toast of "The Medical School and Hospital," which was proposed by the Chairman. The other toasts were "The Queen," "The Old Students," and "The Chairman." The proceedings were enlivened by the strains of a string band, and the result was a most successful evening's entertainment.

LITERARY NOTES.

Messrs. Sampson Low, Marston, and Co. will be the British publishers of the *Twentieth Century Practice of Medicine*, which is now in course of preparation under the general editorship Dr. Thomas L. Stedman, of New York. As we have already stated, Dr. Stedman has succeeded in securing the co-operation of representative men in the United States, the United Kingdom, and the Continent of Europe, so that this "International Encyclopedia of Modern Medical Science" can hardly fail to attain a place of great authority, while the fact that it will consist of twenty volumes, each containing 750 pages, will ensure that the subjects will be treated with completeness. The encyclopedia will be issued to subscribers only at the price of one guinea the volume, bound in cloth (in half morocco, £1 10s.). The first three volumes have already appeared. Vol. I is concerned with Diseases of the Uropoietic System, which are treated by Dr. Francis Delafield, of New York; Mr. Hurry Fenwick and Mr. Reginald Harrison, of London; Dr. Howard A. Kelly, of Baltimore; and Dr. G. Frank Lydston, of Chicago. Vol. II contains essays on Nutritive Disorders, by M. Dujardin-Beaumetz, of Paris; Sir Dyce Duckworth and Dr. Archibald E. Garrod and Dr. T. J. MacLagan, of London; Dr. H. J. Lyman, of Chicago; and Dr. C. H. v. Noorden, of Frankfurt-on-Main. Vol. III is devoted to Occupation Diseases, Drug Habits, and Poisons. The contributors are Dr. W. T. Councilman, of Boston; Dr. A. L. Gihon, of Washington; Dr. Norman Kerr, of London; Dr. G. F. v. Liebig, of Munich; Dr. J. H. Lloyd, of Philadelphia; Dr. George F. Shrady, of New York; Dr. Beaumont Small, of Ottawa; and Dr. J. Stewart, of Montreal.

In *Le Centenaire de l'Ecole Normale 1795-1895*, a work recently issued, M. Duclaux describes the primitive laboratories in which Pasteur made the greater part of his researches on silkworm disease and on the micro-organisms of beer and wine. The investigations on wine were for the most part carried out at Arbois in a laboratory improvised in a café. The sign indicating the purpose to which the premises had previously been devoted had been left in position, and the workers were not infrequently interrupted in their scientific labour by persons seeking for refreshment. Generally, however, the thirsty wayfarer got no further than the doorway, a glance at the appearance of the interior sufficing to show him that he

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Bodleian Library, Oxford, at 8.30 P.M. on Friday, October 20th. Gentlemen desirous of reading papers or of exhibiting cases or specimens are requested to give notice to the Honorary Secretary, Mr. W. LEWIS MORGAN, 27, Broad Street, Oxford, on or before October 8th.

SOUTHERN BRANCH: SOUTH-EAST HANTS DISTRICT.—The next half-yearly meeting will be held on Friday, November 1st, at 4 P.M. at the Medical Library, 5, Piccadilly Road, Portsmouth. Gentlemen desirous of reading papers or of exhibiting cases or specimens are requested to communicate with C. C. CLARKE, Honorary Secretary, 8, Elm Grove, Southsea.

NORTH OF IRELAND BRANCH.—The autumnal meeting of this Branch will be held in the Royal Hospital, Belfast, on Thursday, October 11th, 1895, at 12 noon. Gentlemen who wish to read papers, show patients, or bring any other business before the meeting, will kindly communicate, as early as convenient, with JOHN CAMPBELL, M.D., F.R.C.S., Honorary Secretary, 21, Great Victoria Street, Belfast.

SHROPSHIRE AND MID WALES BRANCH.—The annual general meeting will be held at the Salop Infirmary on Tuesday, October 16th, at 3 o'clock. Members who wish to bring forward any business, to read papers, to show cases or specimens, or to propose any new members, are requested to communicate with the Honorary Secretary not later than Saturday, October 13th.—H. WILLOUGHBY GARDNER, Honorary Secretary, Swan Hall, Shrewsbury.

NORTH OF ENGLAND BRANCH.—The autumnal meeting will be held at the Hydropathic Establishment, Hexham, on Tuesday, October 8th, at 4 P.M. The Honorary Secretary will be glad to receive notice of communications. The dinner after the meeting will be at the same place, at 4.30 P.M. See ad. card. Write care, G. E. WILLIAMSON, F.R.C.S., 8, Eldon Square, Newcastle-on-Tyne, Honorary Secretary.

WEST SOMERSET BRANCH.—The autumnal meeting of this Branch will be held at the Railway Hotel, Taunton, on Friday, October 26th, at 6 P.M. Dinner at 6.30. The subject as settled by the Council for discussion after dinner will be Club Practice, and the discussion will be opened by Mr. Abbott. Short papers or cases may be taken before dinner, and others afterwards. The Honorary Secretary will be glad to receive notice of any case or paper to be communicated to the meeting in the course of the next three or four weeks.—W. M. KELLY, M.D., Honorary Secretary, Taunton.

ROSELAND COUNTRIES BRANCH.—A meeting of this Branch will be held at Kendal on Friday, October 26th. Members desirous of reading papers, etc., please communicate with R. DUNDAS HELM, Honorary Secretary, Carlisle.

SPECIAL CORRESPONDENCE.

PARIS.

The Lourdes Miracles.—The War Health Service.—General News.

DR. BOISSARIE, at a students' Catholic club, showed the patients cured at Lourdes: a blind man who now sees very well; a female patient, an incurable left to die, now in robust health; two sisters with infantile paralysis now walk as easily as others. As each "miracle" appeared the members of the club loudly applauded. M. Peri Morosini, Secretary of the Nunciature, was present. Dr. Boissarie terminated his lecture by saying: "Lourdes is not a scientific question; miracles are everywhere. It is an awakening of the whole Catholic party."

The War Minister has decided that the special manoeuvres of the health service shall take place on October 7th and 11th. On October 7th the lectures will be given concerning the technical material, victualling, and the working of the sanitary arrangements. The following day a lecture will be given concerning marches and the regulation of the health service during the successive phases of war. In the afternoon the staff of the sanitary divisions will be assembled at the docks of the health service and the material be shown to them. At 8 o'clock the division will leave for Montrouge. The third day of the exercises will be devoted to the working of the help and ambulance stations. A mock battle will take place. The sanitary divisions will follow the phases of the battle and the march. On October 10th the hospital organised at Bourg la Reine at the railway station will receive the wounded and remove them to Montrouge. The next morning the removal of the ambulance, and the manoeuvres criticised by the technical director.

M. Aulagner has bequeathed £8,000 to the town of Asnières in order to build a hospital.

The congress on cheap dwellings will be held at Bordeaux on October 20th, 21st, and 22nd. M. Georges Picot, Member of the Institute, will preside.

The inhabitants of the Montmartre neighbourhood have held a meeting to discuss the measures to be taken to remedy the Paris meat famine resulting from the Custom taxes and the sanitary regulations enforced to assure the sale of healthy meat only.

BERLIN.

The late Professor von Bardeleben—"Wild Policlinics."

It is not too much to say that the news of Professor von Bardeleben's death was felt as a stunning blow at the Charité—the hospital which for 27 years had been the scene of his labours, and where all his colleagues were attached to him by feelings of the warmest admiration. Though long past the age when he might have retired with all honour (he was 76 years old), it had never occurred to him to give up even a part of his arduous work. Up to the summer vacation last August he was at his post early and late, and no one who saw him then, looking—with his upright carriage, bright, alert eyes, and long white beard—the very picture of hale old age, could have imagined the end so near. Bardeleben was born in Frankfort on the Oder in 1819, and, after studies in Germany and France, obtained the post of assistant at the Anatomical Institute of Giessen in 1843. In 1849 he was elected to the professorship of surgery in the Greifswald University. Here he laid the foundations of his subsequent fame as an operator, his surgical clinic became a model institute, and he wrote his great work, *Lehrbuch der Chirurgie und Operationslehre*. In 1868 Bardeleben was called to Berlin University as Professor of Surgery and director of the surgical clinic of the Charité. During the wars of 1866 and 1870 Bardeleben, who was created "General-arzt," acted as consulting surgeon in the field hospitals. He was one of the greatest authorities of his time on all subjects connected with military surgery, and was active in helping to forward sanitary measures for the army. In recognition of his military services he was raised to the nobility. But the greatest service he rendered his profession was his adoption of Lister's treatment. He was one of the first in Germany to recognise the immense importance of Lister's discovery, and to learn afresh and to change his teaching by its light. His death was caused by kidney disease of long standing, which took an unexpected turn for the worse.

The Berlin medical societies have taken up the question of the so-called "wild policlinics" institutes under the direction of private physicians that are cropping up all over the city, and where patients rich and poor can have medical attendance for nothing. It has been calculated that about 300,000 cases a year are treated gratuitously, and it is alleged that a large percentage of these are well-to-do people, fully able to pay. Of course this represents a tremendous loss to the Berlin doctors, and it is no wonder that the medical bodies are beginning to agitate for legislation on the subject.

CORRESPONDENCE.

THE EDUCATION OF THE STUDENT IN PRACTICAL MIDWIFERY.

SIR,—Dr. Rentoul, it seems, is going to send out in future from the various universities a thoroughly efficient body of obstetricians who have actually "personally attended" thirty cases.

How many normal cases is a student sure to see in thirty cases? Or out of thirty normal cases how many are likely to go wrong? There can be no certainty in the matter. Six out of thirty would be a very large number of abnormal cases, and yet quite inadequate to render a student efficient in all the possibilities of abnormal labour.

If by seeing thirty cases of labour a student could see for himself anything approaching half the possible accidents and dangers of childbirth and of the puerperal state, marriage would be most undesirable from a female point of view, and very rightly so. Happily for the female sex neither thirty nor

sixty cases of labour will wholly educate a student. The basis of midwifery is a proper understanding of a normal labour both in theory and practice.

Such I understand is the aim of the Scottish Universities, and in consequence six personally conducted cases are all that is exacted of the student. Theoretical and clinical work must account for the rest. Most certainly thirty cases will not. It would be absurd to burden the already over-worked student with thirty cases, unless it could be shown that a very considerable number of these would be sure in most cases to present different features, and that very widely, from the prescribed six.

I have not yet forgotten that during my three months of clinical work at the Edinburgh maternity I was thirteen times out of bed, twice up all night, and once all day as well, to get these six cases. It looks as if Dr. Rentoul wished to kill off some of the rising medical generation, by adding fourfold to this sort of treadmill.

As perfection or even fair proficiency is unattainable by even thirty or sixty cases, the next best thing is to aim at what perfection is possible. That is exactly what is being done in the Scottish schools. Sound practical as well as theoretical instruction in normal labour, and thorough theoretical and clinical instruction for the rest.

The wisdom of the Scottish vote in the Council is obvious and requires no urging to vote differently, or excusing.

Dr. Rentoul, however, requires excusing in presuming to accuse thirty gentlemen of such eminence as the Medical Council of sending out a "death-dealing recommendation." Dr. Leishman never spoke a truer word when he said, "I could communicate more sound instruction in practical details at the bedside in one case of labour than the student would pick up haphazard in the course of a casual attendance on twenty."—I am, etc.,

Edinburgh, Sept. 30th.

A. T. SIMPSON, M.B., C.M.

SIR,—I am not in the habit of reading the lengthy effusions of Dr. R. R. Rentoul which appear in the *BRITISH MEDICAL JOURNAL* from time to time on the above and somewhat cognate subjects. However, whilst scanning your issue of September 25th, my attention was arrested by a table which appears in one of Dr. Rentoul's letters. From this table it would appear that students of the University of Dublin are not required to attend clinical instruction in midwifery nor to see any cases of labour before presenting themselves for their degree examinations.

This statement is most misleading and quite contrary to the actual facts of the case. Had Dr. Rentoul taken the trouble to consult the Dublin University calendar, he would have seen that a student requires "a certificate of attendance on a five months' course of practical midwifery with clinical lectures, including not less than thirty cases." And again: "The candidate must lodge with the Registrar of the School of Physic his certificate of attendance on Practical Midwifery." The candidate is further required to pass an examination in practical midwifery, gynecology, and obstetrical anatomy.

The above quotations will show that Dr. Rentoul's figures as regards Dublin University are misleading.—I am, etc.,

ROBT. S. ARCHER, M.D. Univ. Dublin.

Liverpool, Sept. 30th.

MEDICAL EDUCATION OF WOMEN.

SIR,—It happens that—by an unfortunate accident—I have only just seen Dr. Garrett Anderson's excellent article on the medical education of women in the *BRITISH MEDICAL JOURNAL* of September 7th or I should have asked you at once to allow me to correct an error that it contains respecting education in Edinburgh. She wrote under the impression that all the medical classes for women in Edinburgh were confined to women only, but I think it should be clearly known that this is the case only as regards this School in Surgeon Square. The majority of the classes to which women are admitted outside of our School are mixed classes for men and women, and it is desirable that parents should clearly understand this when sending their daughters to Edinburgh. If they prefer mixed classes they can have them, but if they desire that their daughters should be educated in a separate school of their own, this can only be

obtained by sending them to the Edinburgh School of Medicine for Women.

With regard to health, I heartily agree with Mrs. Anderson that no one who is in any sense an invalid should study medicine, and also that a student must give her whole time to her work. At the same time I do not think that more than average good health is required in anyone who will eschew all other duties, and who will so limit her hours of study as to take plenty of outdoor exercise, and allow herself long nights of quiet sleep. Girls as well as boys often break down quite unnecessarily, not because their health is defective, but because they study in a foolish and headstrong way, ignoring the ordinary laws of hygiene, and destroying their own future by attempting the impossible in the present. Kindly counsel on such points ought always to be available for women students, and those most ready to take it will be least likely to suffer from anything like a breakdown. Indeed I know several young women whose health has much improved during their period of study.—I am, etc.,

SOPHIA JEX-BLAKE, M.D.,

Dean of the Edinburgh School of Medicine for Women.

Edinburgh, Sept. 30th.

THE UNIVERSITY GRIEVANCE IN LONDON.

SIR,—In the letter of "Medical Officer of Health" on the above subject there is one sentence which in fairness to my University, viz., that of Edinburgh, I feel it is my duty not only to enter against it the strongest protest, but to absolutely deny the accuracy of the statement. As I have the honour of being an M.R.C.S.Eng., L.R.C.P.Lond. and L.S.A.Lond., as well as a graduate of the University of Edinburgh, I think I am in a position to judge of the merits of those examinations, and I have no hesitation in saying that it requires harder work and greater knowledge to obtain the Edinburgh degrees than is requisite for the M.R.C.S. Eng. and L.R.C.P.Lond. diplomas. Had your correspondent foreseen the value of a degree he would doubtless have taken one instead of, or in addition to, the two London qualifications, but because he had not that foresight is no reason for his decrying University degrees.—I am, etc.,

Wimpole Street, Oct. 1st.

GEO. STEELE PERKINS.

MEDICAL DEFENCE UNION.

SIR,—The advantages gained by members of the profession who join the Medical Defence Union had never been so clearly demonstrated than they were in a letter to the *Times* dated September 21st, written by a person against whom we had to enter an action for libel on behalf of a member. In this letter he writes: "In this action the medical officer was only a nominal plaintiff. He had joined a medical trade union, and it was this trade union that pursued the action. Had it been the individual only I had to meet no apology would have been signed by me, but the fighting of an irresponsible corporate body was a totally different matter, and entailed possible consequences it was most desirable to avoid." (The italics are mine). I may state that in this action all the costs and a penalty were paid by the defendant, and an ample and satisfactory apology published by him. The words above are the best testimonial to the value of the union ever yet received.—I am, etc.,

A. G. BATEMAN, General Secretary.

King William Street, Strand, Sept. 30th.

PROFESSIONAL ADVERTISING.

SIR,—In the outcry against medical advertising there seems to be a tendency to include under this heading any attempt to make one's professional status known. Although I am altogether against professional touting and consider it disgraceful, yet, on the other hand, when advertising one's books or lecturing is condemned, I think the critic "doth protest too much."

Let us turn to the other professions. The lawyers, by their calling, are self-advertising. In every newspaper we see their names appearing and their speeches reported. They write their "reminiscences" and biographies and advertise their books largely in the public press. Having so many other opportunities for becoming known to the public, might not these autobiographies, etc., be included under professional advertising?

In the Church it is well known that several eminent preachers relate in their sermons their personal experiences and efforts. One especially is noted for his word-painting of scenery and places he has visited. This, surely, is something very much akin to what in the medical profession would be termed advertising.

In the army combatant officers write essays to the periodicals, address public meetings, and give their views and experiences. These in no small measure make "gallant colonels" popular and mark them for future distinctions.

On the contrary, any medical man bringing himself before the public as a good "doctor" is considered a tout. "Medicine," so-called, is no more a sacred and confidential profession than the Church or the Bar. *Mirabile dictu*, we condemn ourselves as touts for popular favour, and the complacent public considers that we must work in the dark, be content with "small thanks" and smaller fees, and "do the good Samaritan" at little profit and great self-denial.—I am, etc.,

September 24th.

DA ET ACCIPE.

Sir,—It seems to me that the rights and wrongs of "professional advertising," when referring to popular scientific books and lectures, are not so much in the thing done but the way in which it is done, or, in other words, it is a question of taste in the doing of it.

I quite agree with "Heretic" that the public ask for and require elementary scientific education (for example, lectures and books), for with every additional step of civilisation comes a slight but proportional increase of personal risk in the use of it, which has to be combated by some elementary scientific educational means as those mentioned above. And who could teach about our profession better than the members of it themselves?

As I have grumbled over a grievance I ought to suggest a remedy. Either let the instruction be given by medical men in the pay of some body corporate (for example, British Medical Council or Government), whose duties will be entirely taken up in this public work. So any advertising concerning their work cannot possibly aid the lecturer, etc., to an increase of income; and jealousy or medical ethics is set at rest. Or raise the standard of the educational examination considerably above its present state. This will act by increasing the expense of the embryo student's school education, which will entail his being taught by better masters and at better schools. This will mean a greater rubbing against great minds and great thoughts, which will give the boy greater powers of judgment, one of which is the power of good taste. Then medical ethics will be a much less harassed subject than now.—I am, etc.,

September 24th.

ONE WHO DOES NOT RIDE A HOBBY.

THE MORTALITY FROM INFLUENZA.

Sir,—In a paper on Professional Advertising, which appears in the *BRITISH MEDICAL JOURNAL* for September 14th, Dr. Potter remarks on the impropriety of giving testimonials to the vendors of patent medicines and foods, and implies that a certain doctor who, in giving such a testimonial, stated that he had attended over 700 cases of influenza without losing a single case, has wilfully told the thing that is not. Dr. Potter continues: "I should doubt if there be one medical man in the whole profession who has attended 700 influenza cases without losing one."

Without entering into the question of giving such testimonials, in which everyone will agree with Dr. Potter, I would remark that I have repeatedly seen similar statements on the mortality from influenza in papers by medical practitioners published in the *JOURNAL* and elsewhere, in which a special line of treatment of that disease was recommended as a particularly successful one, and where this favourable opinion was based on the circumstance that in 600, 700, or 800 cases not a single death had taken place where that treatment had been followed.

I think it therefore desirable to draw attention to the fact, which does not appear to be at all generally known, that the average mortality from influenza, under any line of treatment, is only 1 per 1,000. That disease is dangerous to life

chiefly in habitual drunkards, of whom after all there is not a very great number, while children, who usually constitute the large majority of cases under care, generally recover in spite of the most terrible complications which may have been present, and after coma and other ominous symptoms have set in.

The doctor who gave the testimonial in the instance referred to by Dr. Potter may therefore have told the truth all the same in spite of his indiscretion; but it is far more important to know that the absence of a fatal case in 700, 800, or 900 cases of influenza proves absolutely nothing for the efficacy of any particular mode of treatment which may have been adopted.—I am, etc.,

Harley Street, Sept. 27th.

JULIUS ALTHAUS, M.D.

A QUESTION OF CONSCIENCE.

Sir,—Our first and plain duty is to preserve life, and any coquetting with such cases of conscience as Miss Kenealy describes, however interesting they may be as abstract speculations, is liable to land the unfortunate practitioner in the dock for manslaughter, committed with the best possible intentions. Yet the publication of such distressing cases is of great value, as the more widely they are known the more surely we shall receive the support of all good men and women in our efforts to induce Parliament to sanction preventive regulation, similar to those which, wisely introduced and unwisely repealed, brought, during this too brief period of existence, the priceless blessing of health, not only to men and women, but also to the little children. I write of what I know, having seen the results of both systems, and can recall many cases where I have felt, as Miss Kenealy must have felt, that for the child it would be better to die than to live, and best not to be born at all.—I am, etc.,

September 18th.

SURGEON-MAJOR.

Sir,—Many difficult questions in ethnology might be solved if it could be proved that disease will bring about a permanent change of type. That syphilis will convert a Caucasian child into a Mongoloid, however, is a statement ethnologists will hardly accept without further proof. The comparison, indeed, is entirely superficial and misleading. The Mongolian, it is true, has a wider skull, but this is not due, like that of the syphilitic child, to hydrocephalus. The same may be said of the diminished brain. The Mongolian has smaller teeth, but they are not syphilitic. The Mongolian has no hair on his face, but on the head he grows it in thick profusion, which is precisely what the syphilitic does not. The pigmented skin, the flattened nose, and the occasionally contracted eyelids complete the picture. Meanwhile the solid osseous characteristics of the Mongolian, the small nasal index, the large orbital index, the virtual non-existence of the supraorbital ridges, and the extreme prominence and large size of the malar bones, we look for in vain in the victim of hereditary syphilis.—I am, etc.,

Chelsea, Sept. 26th.

J. FOSTER PALMER.

* * We have received so many letters on this subject, containing, often, repetitions of arguments already used by other correspondents, that we find it impossible to publish all. We print below abstracts of some of the communications received:—

The Author of *Mona Maudslayi* thinks that not many practitioners of her sex will agree with Miss Kenealy's views. Her contention would appear to be that in any given case the individual doctor is to be the judge whether the individual life is worth preserving or not. The statement of such a principle is its refutation, for the wisest of physicians have had to admit errors in prognosis. Though drugs may not cure, they may enable the patient to round the corner and avail himself of fresh air and sunlight and food and sleep, which are Nature's cures.

Surgeon-Captain O'Callaghan, A.M.S., congratulates Miss Kenealy on her courage in formulating in written words one of the many questions of conscience that have perplexed many minds. He thinks that the time may come when the law would hold a man equally guilty in thus defeating Nature by attempting to preserve the life of an individual who may start the stream of life in future generations as a

* *See my Treatise on Influenza, second edition, p. 329.*

man who should let loose a criminal to prey on society. Those who shudder at Miss Kenedy's suggestion may be induced to turn their attention to the only other alternative in the instance quoted—"a strong C. D. Act."

Mr. Lawson Tait (Birmingham), while thinking Miss Kenedy quite wrong in her line of action, finds "T. C. A.'s" lesser moderate and not philosophic. The real reason against Miss Kenedy's course is that, had she given the mother a thorough mercurial course sufficient to save the abortion, both patients might and probably would have been cured.

E. E. W., writing as a woman, dependent on the honest and straightforward dealing of medical men, asks whether, in the case instanced by Miss Kenedy, it was not wrong to withhold treatment from the mother. The individual suffers relief on her doctor to endeavour to relieve suffering whatever its cause, and to minister to the individual without regard to his theories as to what may be best for the race. The individual at any rate should be given a choice.

Mr. A. G. S. Malcolm (Glasgow) mostly considers that in the case instanced by her, Miss Kenedy failed in her duty, since, though she thought mercurials would improve the mother's condition, she failed to prescribe them. Further, the child, by a judicious application of the same treatment, might have been fairly healthy except for some slight blemishes of personal appearance and some more important defects of structure. It might have been a useful member of society. Further, if the mother's health improves the child may yet be born alive, but may be more weakly than it would have been had appropriate treatment been used.

Mr. F. E. Constant (Barrington), writing as one who is not a medical practitioner, is stirred by a perusal of Miss Kenedy's letter to inquire whether ladies are fit for a profession as a very practical as that of medicine. The inner workings of her conscience as disclosed in her letter show, he thinks, that "it is a copious and characteristically feminine." She has, he adds, described in vivid language the "glaring misapprehension of her duty as a medical practitioner to which a lady doctor may be led by her natural impulses."

"A SAFE CHLOROFORM."

Sir.—The cause of death during chloroform inhalation is generally stated to be due to paralysis of the respiratory and cardiac mechanism. The question naturally arises: Can we obviate this dangerous tendency of an otherwise beneficial drug? If we could succeed in combining a compatible, volatile, chemical agent with chloroform which would stimulate the vital centres, and at the same time not materially interfere with the anæsthetic, we might reasonably hope to lessen the present mortality from chloroform anæsthesia. The two best drugs available for combination appear to be: (1) ammonia gas, (2) nitrite of amyl. I have found by experiment that chloroform is not decomposed by liquid ammonia peroxide, *Dryas Pharmaceutica*, in the cold, and I am informed by a well-known chemist that the anæsthetic absorbs 2.6 per cent. of ammonia gas. The same authority has suggested nitrite of amyl, which can also be combined with chloroform.

In my opinion this new form of the drug might be found useful in cases of sudden emergency and for operations on debilitated patients, and those with weak cardiac action; in field hospitals, and on board Her Majesty's ships of war.

The following method of inhalation might be adopted: Given a safe mixture, ordinary chloroform anæsthesia might be induced, and at the critical stage, when the vital centres are liable to failure, the stimulating anæsthetic might be substituted.

I propose to reserve the powerful 2 per cent. mixture for serious cases, and employ a weaker strength (1 per cent.) for inhalation by Lister's method.

It is possible that the ammoniated drug might be found to lessen the after-drowsiness and other unpleasant symptoms.

Surely this matter is worth further investigation. It would be instructive to anæsthesise certain animals with a like combination, and to watch and compare the effects on the pulse and respiration. Messrs. Duncan, Flockhart, and Co., of Edinburgh, have prepared for me samples of pure chloroform, containing 2 per cent. by volume of ammonia gas, and some

other specimens containing .5j amyl nitrite in each fluid drachm. This combination is said to produce "no failure of respiration on heart, and no failure of blood pressure." *Wachsmuth's*.—"One-fifth part of oil of turpentine is added to the chloroform." This mixture is stated to prevent cardiac paralysis.—I am, etc.,

J. DUNCAN MERRIE, M.B. Edin.,
Surgeon, R.N.
H.M.S. Halcyon, Sept. 1. 95.

YAWS AND COCO.

Sir.—In the *BRITISH MEDICAL JOURNAL* of September 28th you review Dr. Nicholls's *Report on Yaws*, and state that in it he expresses doubts as to the identity of the Fijian coco with yaws.

During three years in which I was in the Fijian Medical Service I saw hundreds of cases of coco, and made myself familiar with its aspects both in the natives and East Indians. During the last two years in the British Guiana Medical Service I have seen several cases which were identical in appearance and course with coco, but these in each case were diagnosed by practitioners of local, West Indian, or West African experience as undoubted cases of yaws.

The descriptions of yaws both by Dr. Nicholls and others would serve equally well for coco, and so would the illustrations given in the report. Those illustrations which I considered most typical of coco were those selected subsequently by others as the best of yaws. Coco is not by any means confined to Fiji, but is common throughout Polynesia and Melanesia.—I am, etc.,

C. W. DANIELS, M.B. Cantab.,
British Guiana Medical Service (late Fiji Medical Service).
Crossington, near Liverpool, Sept. 28th.

VACCINATION BEFORE JENNER.

Sir.—During my rambles in Dorsetshire a few weeks ago I noticed an inscription on a tombstone in the little village churchyard of North Matravers as follows: "Sacred to the memory of Benj. Josy Barnstap, who departed this life April 16th, 1816. Born at Yetminster in this county. A honest and upright man. He was the first person (known) that introduced cowpox with inoculation, who from great strength of mind made experiment from the cow on his wife and two sons in the year 1774."

I have since ascertained that there is no doubt as to the correctness of this statement, and the above was a farmer in that neighbourhood, and there remains no doubt that he performed vaccination, at least on his own family, several years before Jenner made the discovery.—I am, etc.,

Bristol, Sept. 26th. G. C. PAULI, M.R.C.S.

* * * There is no reason to doubt the correctness of the statement made upon the tombstone. It was long a matter of traditional belief amongst the dairy farmers in England and in Holstein that cowpox was protective against smallpox. The deliberate introduction of cowpox may therefore well have been adopted by several independent minds. All great discoveries have been anticipated in a similar manner, but it detracts nothing from the greatness of him who first systematizes or renders them available for the purposes of every day life.

1 The Glasgow Committee of the British Medical Association, 1879; Hyderabad Commission, 1880; Von Meering's mixture. Chloroform, 1 vol., dimethylæther, 2 vols.

We regret to learn that Mr. Trimmer, the Secretary of the Royal College of Surgeons, was on Wednesday evening the victim of the robbery with violence which is so common in the neighbourhood of Clare Market. Mr. Trimmer left the College just before 6, and at the corner of Portugal Street met a man who snatched his chain and wallet and made off with them. He attempted to give chase, but was at once knocked down by a confederate of the thief, and, besides the shock, sustained a severe cut on the face. Mr. Trimmer returned to the College, and was at once taken by Mr. Cowell to King's College Hospital, where his injuries were attended to. On inquiry just as we go to press we are pleased to find that Mr. Trimmer is going on as satisfactorily as could be expected.

OBITUARY.

LOUIS PASTEUR,

Member of the Institute of France.

M. PASTEUR died on September 28th, at 5 P.M., at Garches, the portion of the domain of Villeneuve l'Étang, in the city of Paris, placed at his disposal for studying rabies.

Our Paris correspondent writes: The dwelling-house is of the simplest. M. Pasteur's health was excellent until the end of the year 1886, when began the violent attacks on him concerning his rabies researches. The grief these attacks inflicted on him resulted in insomnia, palpitations, and symptoms of astylosia, which obliged him to seek health in the South of France. In 1889 he wintered at Bordighera in the villa M. Bischoffsheim placed at his disposal. The earthquake of that year obliged him to quit the South. He returned to Paris slightly improved in health, but, nevertheless, very ailing. At frequent intervals heart trouble intervened, and albuminuria declared itself. In 1892 slight attacks of uræmia occurred, though the unremitting care and devotion of his family and pupils enabled him to gain a semblance of health. On November 1st, 1894, he had a fresh attack, and was obliged to lay up for some months. He again apparently recovered, and went to Garches, where he appeared to be much better. Later on the excessive heat fatigued him greatly, the heart became weaker, and uræmia again set in. The pupils of the Pasteur Institute took it by turns to watch at his bedside. On Thursday, September 28th, the approach of death was evident. M. Pasteur's intimate friends and absent pupils received telegrams, while MM. Chantemesse and

Metchnikoff were in constant attendance at his bedside. When Dr. Roux arrived Pasteur was all but unconscious and a prey to violent uræmic dyspnoea. On Saturday, September 28th, Pasteur quietly passed away from the scene of his labours, his rewards, and his trials. At 4 P.M. he breathed his last surrounded by his family and his pupils. Dr. Metchnikoff and Dr. Chantemesse prepared the body for the

grave; his arms were crossed on the breast, and a crucifix placed in the hands. On Saturday the Cure of Garches and M. Boulanguin, a Dominican priest, visited M. Pasteur. The body was conveyed to the Pasteur Institute on September 30th, embalmed, and placed in state in the library of the Pasteur Institute awaiting a public burial decreed by the State. The President of the Republic, ministers, students, corporations, and a crowd of sympathisers and notabilities

have addressed telegrams of condolence to Mme. Pasteur and her family. M. Maurice Lemoir, M. Pasteur's nephew, has been authorized to take a portrait of the illustrious *savant* on his deathbed.

Louis Pasteur was born at Dole, Jura, on December 27th, 1822, where his father, an old soldier of the First Empire, carried on the business of a tanner. The father was a man of some intelligence, and made strenuous efforts to give his son the best education in his power, in order that he might become a master at Arbois College. The son commenced his classical studies at that College, and subsequently studied at Besançon, where he obtained his degree of Bachelier des Lettres, and became a supernumerary master of studies. In 1842 he entered as a candidate for the École Normale of Paris, but, passing only fourteenth in this list, young Louis Pasteur devoted another year to study, entering in 1843 as fourth amongst the aspirants. Already he had begun to devote himself to chemistry, and now, under Dumas at the Sorbonne, and Balard at the École, this study absorbed a large portion of his time. Under Delafosse he became a proficient in molecular physics also, and, while listening to this lecturer, struck upon the ideas regarding dissymmetry which at a later period of his life he developed at great length. In 1847 he took the degree of Doctor, and in the following year was appointed Assistant Pro-

fessor of Physics at the Faculty of Sciences at Strassburg. At the end of 1854 he was entrusted, as Dean, with the organisation of the newly-created Faculty of Sciences at Lille. Three years later Pasteur returned to Paris, and was appointed Director of Scientific Studies of the École Normale Supérieure, which post he held from 1857 to 1867. In 1856 the Royal Society of London awarded

*Very sincerely & with consideration
his Disciple*

L. Pasteur

Pasteur the Rumford Medal for his researches relating to the polarisation of light. He was decorated with the Legion of Honour on August 12th, 1853, was promoted to be an officer of that Order in 1863, and a Commander in 1868. In December, 1863, he was appointed Professor of Geology, Physics, and Chemistry at the Ecole des Beaux-Arts, and in 1867 Professor of Chemistry at the Sorbonne, which latter chair he occupied until 1875. In 1869 he was elected a member of the Académie des Sciences (mineralogical section). Honoured in 1868 by the Medical Faculty of the University of Bonn with the degree of doctor, he returned the diploma after the Franco-German war. In 1869 he was elected one of the fifty foreign members of the Royal Society of London. He became an Associate of the Académie de Médecine in 1873, was elected member of the Académie Française in 1881, in succession to M. Littré, and was received on April 27th, 1882. The following year Oxford University conferred upon him the honorary degree of Doctor of Science. In 1887 he was unanimously elected Perpetual Secretary of the Académie des Sciences, replacing M. Vulpian, but, owing to his health and the pressure of scientific labours, he resigned the post two years later, and was made an honorary Perpetual Secretary.

M. Pasteur wrote numerous work relating to chemistry which were favourably received, and for which, in 1861, he obtained the Jecker prize. When, in 1864, he removed to Lille, although still an enthusiast in molecular physics, he regarded it as politic, considering that the staple history of the town was distilling, to devote some of his lectures at the Lille Faculty of Sciences to the subject of fermentation.

It was in a little room on the first storey of a building connected with the old Château de Villeneuve l'Étang that the eminent *savant* died. The chateau was burnt down about twelve years ago, and the outbuildings had been placed at Pasteur's disposal by the Government for his experiments. Nothing could be more simple than the furniture of this chamber, comprising as it does the bed on which his remains were laid as if still in sleep, a few chairs, a table, and a little drugget; while in a cupboard is a small collection of the books which he most loved to read. His mode of life, indeed, has always been very simple—that of the ardent student; and the language which he uttered during his last visit to his native town of Dôle, in a street of which—the Rue des Tanneurs—is a little house where a marble slab commemorates his birth within its walls on December 27th, 1822, was extremely touching. He spoke of his departed father and mother in the most dutiful and affectionate terms, and ere he left he possessed himself of the old signboard which had embellished the paternal tannery, and placed it in his bedroom at the Institute which bears his name. Nothing, too, could be more characteristic of the man than his reply when a Russian doctor who had studied under him announced to the Academy of Science that he had succeeded in curing at Odessa 1,200 persons affected or threatened with rabies. A colleague exclaimed, "This is a fresh triumph for you." "No," he answered, "this is not a triumph for me, but for my method. In such questions the man disappears, the scientific result remains."

Louis Pasteur had been in the enjoyment of fairly good health until some years ago, when certain experiments led him to spend long hours in a very overheated atmosphere. He fell ill, and his medical adviser told him that if he continued that sort of life he would probably shorten his days, and would at any rate be afflicted with paralysis. His reply was that he could not abandon his studies. He felt that he was approaching a discovery, and, happen what might, he must do his duty. Some time afterwards the desired goal was attained, but at the cost of partial paralysis. The use of an arm was lost. Pasteur grew nervous, was liable to tears when demonstrations were made in his honour, and a few months ago he was unable to attend a crowning *fête* in which the Municipal Council of Paris took a leading part, Dr. Roux being obliged to receive and to acknowledge the compliments for both.

Though Pasteur has disappeared, the Pasteur Institute will have lost nothing of its strength. His work will be carried on by a band of self-sacrificing hard-working scientists who grouped themselves round the great man. Of Pasteur's disciples Dr. Maurice de Fleury writes in the *Figaro*: "First and foremost is M. Duclaux, the actual sub-director of the

Institute, who will certainly be called to the direction of the establishment. M. Roux will no doubt succeed him, for though he is likely to modestly refuse, he will be forced to give way. With an incomparable technician like Roux, a searcher of genius like Metchnikoff, accomplished bacteriologists like Chantemesse, Nocard, Charrin, and so many others; with Yersin, with Dr. Albert Calmette, who is seeking the vaccine of the venom of serpents; with Nicolle, who is directing at Constantinople the laboratory which is destined to bar the road westward to the cholera, the Pasteur Institute is in no danger of perishing."

In recognition of his services, and as a reward chiefly for his investigations on fermentation, the National Assembly voted to M. Pasteur a life annuity of 12,000 francs. He was raised to the rank of Grand Officer of the Legion of Honour on October 24th, 1878. In 1882 the Society of Arts awarded the Albert Medal of the Society to M. Pasteur for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silkworms and domestic animals. As might be expected, M. Pasteur's theories found stout opponents, both in his own and foreign countries, especially that for killing the rabbits in Australia by chicken cholera germs; but the honours conferred upon him by almost general consent go to prove that his work was greatly valued, while the orders, doctorates, and honorary diplomas showed the high estimation in which he was held by almost every civilized country. It may be of interest to mention that a decree, dated July 27th, 1870, was signed by Napoleon III and M. Ollivier, raising him to the dignity of Senator, but the decree was never promulgated.

M. Pasteur's contributions to science have appeared in the *Recueil des Savants Etrangers*, the *Annales de Chimie et de Physique*, and the *Comptes Rendus*. He published, in a separate form, *Nouvel Exemple de Fermentation déterminée par des animalcules infusoires pouvant vivre sans oxygène libre* (1863); *Études sur le Vin ses maladies, les Causes qui les provoquent, etc.* (two editions, 1866 and 1872); *Études sur le Vinaigre, ses maladies, moyens de les prévenir, etc.* (1868); *Études sur la Maladie des Vers à Soie* (1870); *Études sur la Bière, ses maladies, causes qui les provoquent* (1876); *Les Microbes* (1878), (with Professor Tyndall); *Examen Critique d'un Écrit Posthume de Claude Bernard sur la Fermentation* (1879). Several memoirs have been published on Pasteur and his work; we may mention one, written by M. Valléry-Radot, under the title *M. Pasteur, Histoire d'un Savant, par Un Ignorant* (1883), which was translated into English by Mrs. Tyndall, and published with a preface by Professor Tyndall in 1884.

Sir Joseph Lister has favoured us with the following brief observations on M. Pasteur's career: It would be impossible in the short time at my disposal to refer even cursorily to the brilliant and far-reaching discoveries of Pasteur which have so widely extended the province of biology and have revolutionised medicine and surgery. I must content myself with a few words regarding his personal characteristics. His acuteness as an investigator in seizing upon essential points and his wonderful lucidity of judgment were only equalled by the patience with which he pursued what he termed *la méthode expérimentale*; and his enthusiasm was tempered by dispassionate caution. In doing battle with the fallacious doctrine of spontaneous generation, he was a keen controversialist; but his utterances were invariably characterised by transparent truthfulness and perfect fairness towards his opponents. His rare modesty and entire freedom from affectation made intercourse with him easy and delightful. Anyone who reads the account he gave in the *Comptes Rendus* of the case of the little boy on whom he first ventured to employ antiseptic injections in the human subject will see clear indication of another feature of his character, loving tenderness of heart. His splendid early work in chemistry and physics proved indeed how dearly he loved pure science for its own sake; yet it was undoubtedly the great joy of his later researches that they directly promoted the good of mankind. In Pasteur the world has lost a personality as beautiful as it was great.

Dr. G. Sims Woodhead sends the following estimate of Pasteur's scientific work: When in 1866 the Royal Society awarded the Rumford medal to Louis Pasteur for his researches on the

polarising effects of tartaric and paratartaric acid few people outside the Royal Society were aware of the singular ability that marked the researches as a result of which such interesting conclusions had been arrived at. The subject was not sufficiently popular to attract general attention, but after a time, as the subject was developed along somewhat different lines, a bloodless battle was waged which shook the scientific world to its very foundations. The same series of experiments which were instituted to show how certain fungi could break up the tartarates into those which polarised light to the right and those which rotated it to the left were utilised to show that no living organisms, however low in the scale, could be developed from any kind of albuminoid material, whilst on the other hand a single organism placed in a nutrient material which contained not a trace of organic matter, but merely ammonia and crystalline salts, could grow and multiply almost indefinitely as long as any food material remained and so long as the products of these organisms did not accumulate in too large quantities. So long as dust and living organic particles were kept out of the richest organic or albuminoid fluid such fluid remained absolutely unaltered as regards the production of living protoplasm. This was the starting point from which all Pasteur's more recent work went out. Without having a sterile soil to begin with it would have been impossible to isolate and study individual organisms as he was afterwards able to do, and without such study the germ theory of fermentation, putrefaction, and disease could never have been demonstrated and applied.

The part that Pasteur played in overthrowing the remnants of the theory of abiogenesis brought his name prominently forward before all educated men. He was no longer the *savant* of the *savants*, he jumped at one bound into a very high place in the popular estimation. This estimation was confirmed when his investigations on unsound wine and its causes, on the silkworm disease, on fermentation, and on vaccination in turn occupied his attention. The wine industry, which had been flagging under the burden of certain wine diseases, the result of insect-rent fermentation, became indebted to him for a method by which such fermentations could be prevented, his process of Pasteurisation stopping all changes after the wine had been bottled. He was also able to improve the method of manufacturing vinegar, whilst his researches on the silkworm disease were not only of great scientific interest, but were of immense practical importance to the silk industry. In all of these his qualities of patience, industry, and technical skill, guided by that touch of inspiration in which consists the difference between the patient observer and the true genius enabled him to arrive at very definite conclusions both as to the cause of the evil and the method to be adopted in dealing with it. His observations on putrefaction and the organisms by which it was set up, and his experiments on the fermentation of beer and the different kinds of yeasts could be used to obtain the best results, completed this part of his work, which really constituted the foundation of all that he has since done. The mycoderma aceti, the "corpuscle" of pebrine or silkworm disease, and the yeast cell became types of which the bacillus of anthrax and the organism causally associated with other disease processes were the antitypes. If it were true that yeast cells or the pebrine "corpuscles" could under certain conditions multiply, always producing the same forms and products, beer in the one case and silkworm disease in the other, was it not probable that the contagium of specific infective diseases was of a similar character? There was evidence of the presence of a living poison or of a living organism that had the power of producing a poison; there was evidence, too, of the multiplication of this living organism, as only could the disease run such a definite course, gradually increasing in intensity, on some such supposition. He had observed that during fermentation there was a similar process of multiplication of yeast cells and a formation of considerable quantities of the product of the essential form of cell when acting on media of certain kinds, the products altering with the nutrient medium. After a time the growth became interfered with by the accumulation of the products of fermentation, especially as the nutrient materials were used up, until at length the yeast cells, in place of developing young cells, died off, and the process ceased. This corre-

sponded so accurately with the rise and fall of the specific symptoms of infective diseases, that to a man of Pasteur's keenness of intuitive perception the analogy was complete enough to suggest the line of research which has borne such abundant fruit. It is the keenness of perception and this power of applying all knowledge that raised Pasteur to the position that he occupied in the scientific world. Other men might supply facts, Pasteur used them. To him a fact was merely a stepping stone to further knowledge, or a brick in the great edifice of Nature. As Pasteur built up his work, that which he was leaving below him always served first as an outlook tower, and secondly as a foundation on which a greater superstructure might be reared. He applied the touchstone of experiment to the nebulous theories and half-proved facts of his predecessors, separated that which was lasting and sound from that which was false and specious, where gaps were to be filled in he toiled until they were made good, and then fitted his own theories into the scheme on which he was engaged, with the result that no department of research on which he engaged did he fail to illumine, whilst many questions that he worked at were completely revolutionised by his touch.

It has been said that the time was ripe for the advent of the man, and that Pasteur was peculiarly fortunate in his selection of subjects at which to work. He, however, like his great colleague Lister, was the man for the time for where others had worked and passed on these men thought and worked and achieved. Pasteur never evolved his theories from his inner consciousness: he built them up, but when the lighthouse was completed he did not stop until the lantern was lighted.

The great work of Pasteur's life from the point of view of the surgeon and the physician was his gradual development and proof of the germ theory of disease. It is easy to say that it followed naturally on his investigations on fermentation, but then only a Pasteur could have proved either of them. Much collateral work was done, and Koch in Germany worked out much that concurred with and some things that anticipated Pasteur's discoveries, but to Pasteur must be given the honour of proving that specific infectious diseases were due to the action of specific infective organisms. Even the mode of infection was indicated, and the possibility of multiplication of disease organisms, both outside and within the human and animal body. He studied their conditions of growth and the effects of one attack of a specific disease upon subsequent attacks. He noted that these pathogenic organisms could be modified by heat and by the action of various chemical reagents, and he finally sought to modify the attack of a disease by infecting with a modified organism such a modified attack acting as a protection against the more severe forms of the same disease set up by more active organisms. Whatever may be Pasteur's claim to honour, it undoubtedly rests upon the work he has done in connection with the study of the etiology and prophylaxis of specific infective diseases. One idea is the root from which his work branches in all directions. Throughout he followed one line of thought and reasoning, but he never took a step forward until he was perfectly certain of the solidity of the ground on which he already rested. No labour was grudged, no time or energy spared in the filling up of the gaps of the work of each stage as he advanced. This it is that makes his work so reliable, and assures to it a permanence than can be hoped for the work of but few.

Many are willing to acknowledge the great and outstanding merit of Pasteur's earlier work who cannot be brought to appreciate the value of his later investigations. The two, however, cannot be separated; the one follows the other as naturally as daybreak follows the dawn. The investigations on immunity constitute the greatest advance on the study and treatment of disease that has been made during the present century, and the prospect of further advances on the same lines cannot yet be limited. Those who know Pasteur's work recognise the benefits conferred by his investigations, whilst even those who scoff at his experiments on the production of vaccines and the vaccination method of the treatment of such diseases as anthrax and hydrophobia are fated sooner or later to receive benefits directly or indirectly from the hands of the man whom they have reviled without either stint or reason, but whom France and the whole scientific

world were delighted to honour, and whom now they mourn most deeply.

We regret to have to record the death of Mr. CHARLES PALMER PHILLIPS, the Senior Commissioner in Lunacy, on September 17th. Mr. Phillips, who was born in 1822, was educated at Eton and Oxford, and was called to the Bar in 1846. He was appointed Secretary to the Commissioners in Lunacy in 1862, and became a Commissioner in 1872. During the thirty years for which he was connected with the Commission he took the deepest interest in its work, and devoted himself heart and soul to the duties which he had undertaken. He had a strong sense of their responsible nature, and brought to them not only wide knowledge and an absolute uprightness, but also a kindness of disposition which shone through every act of his official as of his private life. Mr. Phillips died literally in harness, for it was on his return from holding an official inquiry which had caused him much anxiety that he was seized with a fatal attack of cardiac syncope.

MEDICO-LEGAL AND MEDICO-ETHICAL

W.J.R. will do wisely not to accept the patient's statement of the case but to communicate direct with the medical man.

PROFESSIONAL SECRECY IN THE UNITED STATES

The Legislature of Pennsylvania has passed a law which was signed by the Governor on June 11th providing protection for medical men called as witnesses against questions which might injure the good name of their patients. The law is entitled "An Act to prevent physicians and surgeons from testifying in civil cases to communications made to them by their patients." It runs as follows: 'Section 1. Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in general assembly met, that it is hereby enacted by the authority of the same that no person authorized to practice physics (*sic*) or surgery shall be allowed in any civil case to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity, which shall tend to blacken the character of the patient, with out his consent.

ADVERTISING HANDBILL.

A correspondent sends us a handbill, of which the following is a copy. He states that it is widely distributed in the neighbourhood by three men. Our correspondent considers that such a handbill should be condemned. To this opinion we apprehend there will be no dissentient among our readers. The offence of professional advertising is aggravated in the present instance by the way in which an honourable office is paraded:

LAMBETH WALK SURGERY.

101, Lambeth Walk, S.E.

Resident Physician, Dr. E. J. Smith (late House-Surgeon to
Quartermaster General Hospital).

Dr. E. J. Smith (late House-Surgeon to Charing Cross Hospital) resides on the premises and personally attends to all cases.

ADVICE AND MEDICINE

Vaccination.
Patients attended in their own homes.

Hours of Consultation					
Mornings	...	9 till 12	Mornings	...	11 till 12
Evenings	...	6 till 10	Sundays	...	7 till 9

CHANGE OF ADDRESS

A. WISEMAN.—When impracticable to notify personally the change of residence, the most unexceptionable mode is to transmit a *change of address* note of a well-executed *fascimile* thereof, on notepaper, to the local post-office, to the nearest post-practitioner; or to enclose an ordinary address card with the *Change of Address* inserted at the top, the old address in the lower right corner being defaced by a black line, and the new one engraved in the left-hand corner, or vice versa.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL STAFF EXCHANGE

The change for forwarding notices respecting Exchanges in the Army Medical Department is to be, 61, which should be forwarded in stamps or post office order with the notice. The last post on Wednesday is the latest by which these communications can be received.

A SUMNERIAN MAJOR serving in Royal wishes for an exchange which would give him about three years at home. Address, stating terms, to G. L. H., care of Messrs. Host and Co., 17, Whitehall Place, London, N.W.

THE NAVY.

The following appointments have been made at the Admiralty: JOHN GRANT, Surgeon, to the Comberford, September 28th; RICHARD L. PRICK, Surgeon, to the Fined, additional, September 28th.

THE ARMY MEDICAL STAFF

THE ARMY MEDICAL STAFF.
SURGEON-GENERAL JAMISON HUGH MASSIE, M.D., O.B., died at Bourne-
mouth on September 27th, aged 75 years. He entered the service as
a Surgeon in 1842, and served in the Crimea, India, and the Sudan.
He was promoted Surgeon-General in 1903, and retired in 1908. He served
as Assistant Surgeon in the 21st Regiment towards the close of the Boer
campaign in 1894; in the Eastern campaign of 1895 as Surgeon of the
17th Lancers, including the operations at Lushank and McKee's Farm;
the battles of Alma, Inkerman, and the Trenches; and the capture and
fall of Sebastopol (medal with four clasps, 5th class of the Medjidie
and Turkish medals), being recommended for promotion to the rank of
Lieutenant-General in 1896. He served in the Boer campaign of 1899
as Surgeon of the 2nd Dragoon Guards in the
Indian campaign of 1898-99, including the siege and capture of Lushank,
action of Kooree, and Trans-Gogra affairs at Bungoon (medal with clasps),
and acted as Principal Medical Officer with Brigadier Barker's Column in
the campaign of Oude during a portion of 1899-99. He was nominated
Companion of the Bath in 1899, and was granted a reward for dis-
tinguished service in 1899.

INDIAN MEDICAL SERVICE

INDIAN MEDICAL SERVICE.
BRIGADE-SURGEON-LIEUTENANT COLONEL F. A. SMITH, Bengal Establishment, has retired from the service from October 30th. He was superannuated Assistant Surgeon October 1st, 1890, and served with the Kharak expedition in 1886-87, receiving the Frontier medal with two clasps.

Brigade Surgeon-Lieutenant-Colonel H. R. PURVES, Bengal Establishment, has also retired from December 4th next. His first appointment dates from October 2nd, 1885.

The retirement from the service is also announced of Surgeon Lieutenant-Colonel E. B. RUTTLEDGE, Bengal Establishment, from October 1st. His commission as Assistant Surgeon dates from October 1st, 1889.

ARMY MEDICAL RESERVE

SURGEON-CAPTAIN R. O. M. POOLEY, having resigned his volunteer appointment, ceases to be an officer of the Army Medical Reserve, October 2nd.

Surgeon-Lieutenant HENRY D. BROOK is promoted to be Surgeon-Captain, October 2nd.

Surgeon-Lieutenant HAMILTON CHAMBERS REID, M.B., Glasgow Companies Volunteer Medical Staff Corps, is appointed Surgeon-Lieutenant, October 2nd.

THE VOLUNTEERS

The services of Surgeon-Lieutenant C. MALCOLM, 2nd West Riding of Yorkshire (Leeds) Engineers, Fortress and Railway Forces, Royal Engineers, are dispensed with, October 2nd

Surgeon-Lieutenant J. W. TALENT, M.R., 3rd Volunteer Battalion the Manchester Regiment, has resigned his commission, October 2nd.

THE SURREY VOLUNTEER BRIGADE.

We are glad to be able to state that in the list of brigades without bearer companies furnished by a correspondent, Surrey was wrongly included; it has had a brigade bearer company for nearly a year.

MAJOR-GENERAL LORD METHUEN ON BEARER COMPANY
RESERVISTS

Lord Methuen's report on the first mobilization of a portion of the 1st Army Corps contains the following on bearer company reservists: "As to these the general physique is reported to be not equal to the men's work on service; they behaved well, but their knowledge of first-aid, and first aid, and of care of wounded, was very poor. The men apparently having forgotten their carrier instruction. As to these from the men on whom the Medical Department will have in part to rely for attending to the well being of the sick and wounded." Lord Methuen's report will surely tend to some action on the part of the War Office.

INDIAN BELIEFS, ARMY MEDICAL STAFF

Some 44 officers of executive rank return to England this training season, and will have to be relieved by officers now serving at home. Of the four Army Corps the Punjab Command sends home 12 officers, Bengal 11, Madras 18, and Bombay 8.

HEALTH OF THE COUNTRY FORCE.

The health of the Central Field Force on August 26th was nominally 18.33 per cent, but two regiments (the Buffords and East Lancashire) were then en route to India. The total number on the list at that date was 22, of whom 21 were British.

VOLUNTARY AMERICAN SCHOOL OF INSTRUCTION.

The winner of the first prize was Mr. J. H. Smith, who has been awarded \$100.00. The second prize was won by Mr. J. H. Smith, who has been awarded \$50.00. The third prize was won by Mr. J. H. Smith, who has been awarded \$25.00. The fourth prize was won by Mr. J. H. Smith, who has been awarded \$10.00. The fifth prize was won by Mr. J. H. Smith, who has been awarded \$5.00. The sixth prize was won by Mr. J. H. Smith, who has been awarded \$2.50. The seventh prize was won by Mr. J. H. Smith, who has been awarded \$1.25. The eighth prize was won by Mr. J. H. Smith, who has been awarded \$0.625. The ninth prize was won by Mr. J. H. Smith, who has been awarded \$0.3125. The tenth prize was won by Mr. J. H. Smith, who has been awarded \$0.15625.

will conclude at 8 o'clock on December 19th. It is expected
for general information that men can be taken in other classes
after October 17th. All those who have recently joined for a
course of instruction are on Major T. F. Floodwood, P. M.
Cor., Camp Town Volunteer Medical Staff Corps,
Australia, and Surgeon Captain J. H.

INDIA AND THE COLONIES.

INDIA.

THE INDIAN MEDICAL SERVICE.—The *East Coast News* (Madras Presidency), commenting on Mr. Ernest Hart's address in the Public Medical Association of the recent meeting of the British Medical Association, deals clearly and ably with the subject of reconstruction. The article proceeds to describe the present arrangements as a state of affairs that "would not be suffered to exist in England," and emphasises the point for which Mr. Hart contends—namely, that "The Civil Medical Department must be separated from the Military if any lasting benefit is to be derived." It also urges "the separation of the medical from the sanitary work." The article sums up its views by the following striking language: "All these matters put together show that there is something wrong in the present system of medical aid in India; and we must emphatically endorse the opinion of Mr. Ernest Hart that the whole system of the Indian Medical Service must be remodelled. The wonder is that the system has continued so long."

PUNJAB LUNATIC ASYLUMS.—There are two asylums in the province of the Punjab, one at Lahore, containing 300 inmates, and one at Delhi, containing 100. The number of lunatics under confinement bears a very small proportion to the population of the province, which is about 21,000,000. Not only there seems to be any tendency to increase. Female lunatics constitute less than one-fourth of the inmates. The report for the year 1894, by Surgeon-General D. O'C. Raye, M.D., indicates that about 40 per cent. of the admissions were discharged cured, and that the death-rates of the two asylums were 16 and 17.12 per cent. of average strength respectively. Pneumonia, tubercle, and dysentery were the chief causes of death. Figures purporting to show the causes of lunacy indicate that cholera, garga, and bang (Indian hemp) are credited with about one-half of cases in which a cause is assigned, but the sources of information are very doubtful and the value of all such statements in India very questionable. Industrial occupations are the chief instrument of treatment, 183, or more than half of the inmates being employed. The work done materially reduces the cost of maintenance, which amounts to about 55 rupees per head per annum, or, at the present rate of exchange, less than 4s. sterling.

VACCINATION IN ASSAM is not in a satisfactory plight. The successful operations of 1894-95, as reported by Surgeon-General A. Stephen, M.B., bore a rate of 28 per 1,000 of population, which is much below the birth-rate. The ratio of successful results was only 57 per cent. in primary vaccination and 61 in revaccination. Each vaccinator performed only 700 operations, the lymph supplied by the animal lymph depot was unsatisfactory. Small-pox continues rife in the province and no impression appears to have been as yet made on the prevalence by vaccination. Inoculation is still practised in some places and the results of the year under report compare unfavourably all round with those of recently preceding years. It is well to realise these shortcomings, and it is to be hoped that the administration and the Sanitary Commissioner having done well will set vigorously to work in the direction of more numerous and effective operations.

DISEASES IN THE HYDERABAD ASSIGNED DISTRICTS.—Surgeon-General Colonel C. C. Little's report for the year 1894 indicates that 8 hospitals and 30 dispensaries were in operation during the year, in which were treated 4,754 indoor and 344,778 outdoor patients. The diseases treated were mostly malarial fevers, digestive disorders, eye and skin diseases, worms, chest complaints, and ulcers. The attendance is increasing, and the number of surgical operations is also growing larger. Some of the hospital assistants in charge of dispensaries are commended for diligence and skill in this direction. A trial is being made in these provinces of a system of leaving small fees for advice and medicine from persons who are able to pay for treatment. The plan is said to promise well. Re 1,000 were received during the year on this account. The financial condition of these institutions is satisfactory, and it is evident that they are doing good work. A hospital for women and children, under a lady doctor, was opened in connection with the Lady Dufferin Fund in January, 1895.

WESTERN AUSTRALIA.

[By an accidental error in our issue of September 21st a paragraph giving the result of the inquiry recently made into the affairs of the Christchurch Hospital, New Zealand was placed under the heading of the Cue Hospital, Western Australia.]

THE CUE HOSPITAL.—Judging from the reports of public meetings and from letters which have been forwarded to us there is considerable excitement at Cue about the dismissal of Dr. Monteth, the late resident medical officer, and the appointment of Dr. Ramsey in his stead. The information at our disposal, however, is too indefinite to enable us to speak decidedly on the subject. Not only are personal matters involved, but also questions as to the jurisdiction of the resident magistrate, the relation of the medical officer to the central Government, the terms of his appointment, and the scope of the Hospital Act, 1894. On these matters our information is too incomplete for us to form a judgment, although *prima facie* Dr. Monteth appears to have good cause for complaint.

NEW SOUTH WALES.

THE LEPROS AT LITTLE BAY.—On December 31st, 1894, there were 40 lepers in the lazaret at Little Bay, near Sydney, including 5 new patients admitted during the year; two of these were Australians, one a German, another an Indian, and the last a native of New Caledonia; 1 of the white lepers died during the year. The total number of patients admitted since 1882 is 88, 6 of whom were females and natives of New South Wales. Their nationality was as follows: Natives of New South Wales, 16, of whom 4 have died; Queensland, 1; China, 20, of whom 10 died; India, 2; West Indies, 1, who was discharged in 1885; Java, 1; England, 1; Fiji, 1; Solomon Islands, 1; New Zealand, 1; New Caledonia, 1; and Germany, 1.

MEDICAL NEWS.

DR. JAMIESON of Brodick has been appointed Sheriff Substituted of Banffshire.

MR. WYNNDHAM RANDALL, Public Vaccinator of the Central District of Bridgend and Cowbridge Union, has been awarded the grant for successful vaccination for the fourth time in succession.

THE winter session of Toynbee Hall opened on Saturday, September 28th, with the usual *conversations*. During the course of this session, Mr. Tait, Assoc.R.C.S., F.O.S., and Mr. Chalmers Mitchell, M.A., F.Z.Sc., will give lectures on chemistry and biology respectively; and popular lectures in science will be given by Professor Michael Foster, Professor Horsley, Mr. Ernest Hart, Professor Gotch, the Master of Downing College, Mr. Preece, Professor Armstrong, and Professor Silvanus Thompson.

A QUARANTINE BRUTALITY.—Under this title the *Medical Record* of New York tells an almost incredible story of the fate of an unhappy sufferer from small-pox. He was expelled from Arkansas and refused admittance into Mississippi. "As he could not well remain in or on the Mississippi River until the disease ran its course, he attempted to evade the quarantine and land on the river bank in the latter State, but was shot and killed by one of the quarantine officers." Even a British antivaccinator might prefer compulsory vaccination to the alternative of death by drowning or shooting.

SIR HENRY ROSCOE, in addressing the students at the presentation of the prizes at the Morley Memorial College, Waterloo Road, on October 1st, referred to the death of M. Pasteur, and said all the world of science mourned the loss of that great man. Pasteur was a great man because he did great things, because he lived for others, because he spent his time in seeking to improve the condition of mankind. All scientific men and all who were interested in the progress of humanity grieved at his loss.

THE ARTIFICIAL LARYNX AT THE ANTIPODES.—A case is reported from Melbourne in which an artificial larynx, devised by Professor Anderson Stuart, of the University of Sydney, has been applied successfully. In 1874 Professor Billroth applied an instrument invented by Dr. Gussenbauer to a patient whose larynx had been extirpated with considerable success, and since then various modifications have been repeatedly made use of. Of these Treves (*Operative Surgery*) mentions Irvine's modification of Gussenbauer's instrument as being most generally satisfactory, but doubtless adaptation to the individual case will usually be necessary; and we congratulate Professor Stuart on his success.

ENTRANCE SCHOLARSHIPS.—At University College, London, the Medical Entrance Exhibitions have been awarded as follows: To Mr. Thomas O. Savage an exhibition of 131 guineas, to Mr. H. W. Reynolds and to Mr. William Reith Scroggie an exhibition to each of 55 guineas.—At Guy's Hospital the Entrance Scholarship in Arts, of the value of £100, was awarded to Mr. G. Lewin, and the second Scholarship, of the value of £50, to Mr. C. G. Gibson. Honorary certificates were awarded to Mr. M. Feldman, Mr. F. S. S. George, Mr. H. F. Hatfield, and Mr. H. D. Kempthorne. The Entrance Scholarship in Science, of the value of £150, was gained by Mr. P. W. L. Camps, and the second, of the value of £60, by Mr. S. Hodgson. Certificates were awarded to Mr. C. A. Miller and Mr. D. Forsyth. The Entrance Scholarship in Arts for dental students, of the value of £20, was awarded to Mr. H. A. G. Butler.

MEDICAL VACANCIES.

The following vacancies are announced:

BUCKLOW DISTRICT COUNCIL.—Medical Officer of Health. Salary, £150 per annum, inclusive of travelling expenses and postages. Applications, with three recent testimonials, endorsed "Medical Officer of Health," to George Leigh, Clerk to the Rural District Council, Council Office, Bexton Road, Knutsford, by October 9th.

CARNARVON JOINT SANITARY DISTRICT.—Medical Officer of Health, must be between 25 and 40 years of age, doubly qualified. Must

devote his whole time to the duties, and have a knowledge of the Welsh language. Appointment for five years. Salary, £994 per annum, inclusive of all expenses, except those incurred for such books, stationery, and apparatus required in the performance of the duties. Applications, endorsed "Application for Office of M.O. Health," to J. H. Thomas, Clerk, to the Joint Committee, 14, Market Street, Carnarvon, by October 14th.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY, Chesterfield.—Junior House-Surgeon and Dispenser. Salary, £80 per annum, with board, apartments, and laundress. Applications to the Secretary by October 14th.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glass Road, Shadwell, E.—Assistant Physician to see out-patients. Must be Fellow or Member of the Royal College of Physicians of London. Applications to Thomas Hayes, Secretary, by October 24th.

EAST SUSSEX COUNTY COUNCIL.—Consulting Medical Officer. Appointment for one year. Honorarium, 100 guineas and travelling expenses. Applications to F. Forrifield, Clerk to the County Council, County Hall, Lewes, by October 14th.

ESSEX AND COLCHESTER HOSPITAL.—House-Surgeon, doubly qualified. Salary, £80 per annum, with board and lodging in the hospital. Applications to the Committee by October 14th.

GLASGOW MATERNITY HOSPITAL.—Obstetric Physician and Assistant Obstetric Physician. Applications to Arthur Forbes, Secretary, 146, Buchanan Street, Glasgow, by November 8th.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House-Physicians. Applications and testimonials to W. Theobald, Secretary, by October 10th.

LONDON HOSPITAL, Whitechapel, E.—Medical Electrician, must be qualified and registered under the Medical Act. Applications to G. Q. Roberts, House-Governor, by October 19th.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Resident Medical Officer for the Institution at Bowdon, Cheshire. Salary, £80 per annum, with board, apartments, and washing. Applications to C. W. Hunt, Secretary, by October 14th.

METROPOLITAN HOSPITAL, Kingsland Road, N.E.—Assistant Surgeon. Must be Fellow of the Royal College of Surgeons of England. Applications and testimonials to Charles H. Byers, Secretary, by October 7th.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich Road, S.E.—Junior Resident Medical Officer. Salary, £20 per annum, with board, attendance, and washing. Post tenable for six months, with prospect of re-election as Senior. Salary, £30 per annum. Applications to the Honorary Secretary or Secretary by October 11th.

PARISH OF DURNES, Sutherlandshire.—Medical Officer. Guaranteed salary, £150 per annum, with practice, free house, and garden. Applications to Robert Sutherland, Inspector of Poor, Durness, by October 10th.

PARISH OF ST. LEONARD SHOREDITCH.—Male Second Assistant Medical Officer for the Infirmary, Hoxton Street, N.—Salary, £20 per annum, with rations, furnished apartments, and washing in the infirmary. Must devote his whole time to the duties of the office. Applications to the Medical Officer, 204, Hoxton Street, London, N.

PARISH OF ST. MARY, Islington.—Resident Assistant Medical Officer for the Workhouse and Infirmary. Salary, £20 per annum, with rations, apartments, and washing, or an allowance in lieu of same. Applications to Edwin Davey, Clerk, by October 8th.

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke Road, Brighton.—House Surgeon; doubly qualified. Salary, £80 per annum, with board, lodging, and washing; no stimulants. Applications to the Chairman of the Medical Committee by October 6th.

ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.—Resident Medical Officer (House-Physician); doubly qualified. Appointment for six months but eligible for re-election. Board, residence, and washing provided. No salary. Applications to the Secretary by October 14th.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.—Resident Medical Officer. Appointment for six months, when re-election is required. Salary at the rate of £80 per annum, with furnished apartments and board. Applications to the Secretary by October 14th.

SHEFFIELD ROYAL HOSPITAL.—Junior Assistant House Surgeon, unmarried. Salary, 60 guineas per annum, with board (exclusive of wine and beer) and lodging. House-Physician, unmarried. Appointment for one year. Board (exclusive of wine and beer), lodging, and an honorarium of 25 guineas. Applications to Dr. Sinclair White, Secretary to the Honorary Medical Staff, by October 14th.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—House Surgeon. Salary, £80, with board and residence. Applications and testimonials to J. Walter Wilson, Honorary Secretary, by October 14th.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—Assistant House Surgeon. Appointment for six months, but renewable for a further period of six months. Board and residence and an honorarium of £10. Applications to J. Walter Wilson, Honorary Secretary, by October 14th.

SUSSEX COUNTY HOSPITAL, Brighton.—Fourth Resident Medical Officer, doubly qualified, unmarried, and under 30 years of age. Salary not exceeding £50 per annum, with board, washing, and residence in the hospital. Applications to the Secretary by October 2nd.

SWANSEA HOSPITAL.—House-Physician. Salary, £80 per annum, with board, lodging, and laundress. Appointment for one year. Applications to Jno. W. Morris, Secretary, 9, Castle Street, Swansea, by October 9th.

WIRRAL CHILDREN'S HOSPITAL, Woodchurch Road, Birkenhead.—Resident House Surgeon (lady or gentleman). Salary, £50 per annum, with board, lodging on the premises, and washing. Applications to P. W. Atkin, Honorary Secretary, 26, Lord Street, Liverpool, by October 12th.

MEDICAL APPOINTMENTS.

AITKEN, Chas. Crawford, M.B., C.M. Edin., appointed Junior House-Surgeon, Cumberland Infirmary, Carlisle.

BAHR, John, M.B., C.M. Glasg., reappointed Medical Officer of Health to the Rishton Town Council.

BEALE, P. T. B., F.R.C.S. Eng., appointed Demonstrator of Histology and reappointed Lecturer on Elementary Biology in King's College, London.

BIERNACKI, John, M.B., C.M. Glasg., L.R.C.P. Ed., appointed Medical Superintendent of the West Ham Fever Hospital.

BOULTON, A. E., M.R.C.S. Eng., L.S.A., appointed Medical Officer of Health to the Horncastle Rural District Council.

COLBY, J. G. E., M.A. Oxon, M.B., B.Ch., appointed Medical Officer of Health for the Malton Rural Sanitary District and for the Morton Rural Sanitary District.

COLLINS, A. B., L.R.C.P. Lond., M.R.C.S., appointed Medical Officer for the Yapton District of the Westhampnett Union.

COOK, Mr., appointed Assistant Medical Officer to the Poorhouse of the Greenock Parish Council.

EFFER, W. Kingston, M.B., M.R.C.P., appointed Assistant Physician to the City of London Hospital for Diseases of the Chest, Victoria Park.

GIDLEY, G. G., L.R.C.P. Lond., M.R.C.S., appointed District Medical Officer to the Tiverton Union.

GORDON-SMITH, J., L.R.C.P. and L.R.C.S. Edin., appointed Assistant Colonial Surgeon, Gold Coast.

HOLTON, F. W. P., M.R.C.S. Eng., L.S.A., appointed Medical Officer for the Tenth District of the West Ham Union.

INNES, John C., L.R.C.S. Edin., reappointed Medical Officer for the Matlock Bath and Cromford Districts of the Bakewell Union.

JOHNSTON, Mr. J. W., appointed Medical Officer for the Workhouse and First District of the Fordingbridge Union, *vice* G. B. R. Paine, M.R.C.S. Eng., resigned.

KENDALL, Bernard C., M.R.C.S., L.R.C.P. Lond., appointed Medical Officer for the Wendron District of the Helston Union, *vice* C. F. Seville, M.B. Lond., resigned.

LAIRD, Dr. F., appointed Medical Officer for the Ravensthorpe District of the Dewsbury Union.

LAWSON, T. C., M.R.C.S. Eng., L.S.A., appointed Medical Officer for the Stogursey District of the Williton Union.

LEIGH, Dr. Albert, appointed Medical Officer for the Malpas District of the Whitechurch Union, Salop.

MACDONALD, James, M.A. Edin., M.B., appointed Medical Officer of Health to the Carlisle Rural District Council.

MCAUGHT, James, M.D., appointed Medical Officer of Health to the Kawtenstall Town Council.

MONK, H. G. H., M.R.C.S., D.P.H. Eng., appointed Medical Officer of Health and Public Analyst to the Leicester Town Council, *vice* J. Priestley, B.A. Lond., M.D. Edin., resigned.

RICHARDS, Mr. W. H., appointed District Medical Officer to the Cardiff Union, *vice* Mr. J. Llewellyn, resigned.

ROBERTSON, J. A., M.D. Glasg., appointed Medical Officer of Health for Peterborough, *vice* W. E. Paley, M.B. Durh., F.R.C.S. Eng., deceased.

ROMER, Mr. Frank, appointed Medical Officer for the No. 3 District of the Malmesbury Union, *vice* A. E. Clarke, L.R.C.P.L., M.R.C.S. Eng., resigned.

THOMAS, Dr. J. T., appointed Medical Officer of Health and Port Medical Officer at Lowestoft.

TYLCOTE, T. H. L., appointed House-Surgeon to the Lancaster Infirmary.

WALKER, Dr. A., appointed Medical Officer of Health to the Westlade Urban District Council.

WESTON, Dr. G. H., appointed Medical Officer for the No. 3 District of the South Stoneham Union.

DIARY FOR NEXT WEEK.

MONDAY.

LONDON POST GRADUATE COURSE, Royal London Ophthalmic Hospital, Moorfields, 1 P.M.—Mr. W. Lang: Clinical Examination of the Eye. London Throat Hospital, Great Portland Street, 5 P.M. Mr. W. R. H. Stewart: Examination of the Ear.

TUESDAY.

LONDON POST GRADUATE COURSE, Bethlehem Royal Hospital, 2 P.M.—Dr. Percy Smith: Acute Mania.

WEDNESDAY.

LONDON POST GRADUATE COURSE, Royal London Ophthalmic Hospital, Moorfields, 5 P.M.—Mr. A. Quarry Sillcock: Choroidal Affections, with Illustrative Cases.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C., 3 P.M.—Lecture by Dr. Beccor.

HUNTERIAN SOCIETY, 630 P.M.—Address by the President, Mr. Charters J. Symonds. Mr. F. Rowland Humphreys: The Infectious Nature of Rheumatism.

ENTOMOLOGICAL SOCIETY OF LONDON, 20, Hanover Square, W., 5 P.M.—Cases will be shown Dr. Leonard Roper and Mr. Charters Symonds. Pathological specimens by Dr. Felix Semon and Dr. Scanes Spicer.

WEST LONDON HOSPITAL, Hammer Smith, W., 5 P.M.—Mr. S. Paget: Surgical cases (Post-mortem cases).

SOUTH-WEST LONDON MEDICAL SOCIETY, Waterloo Infirmary, St. John's Hill, New Wandsworth, 8 P.M.—J. B. Neal will show several cases of interest from the infirmary.

THURSDAY.

LONDON POST-GRADUATE COURSE, Hospital for the Paralysed and Epileptic, Queen Square, 3 P.M.—Dr. Gowers: Clinical Lecture. Hospital for Sick Children, Great Ormond Street, 3 P.M.—The Medical Registrar: Pathological Demonstrations. Central London Sick Asylum, Cleveland Street, 5.30 P.M.—Mr. John Hopkins: Cases in the Wards.

BRITISH GYNÆCOLOGICAL SOCIETY, 20, Hanover Square, W., 8.30 P.M.—Specimens by Dr. Collins, of Cardiff. Dr. R. H. Hodgson: A Multilocular Ovarian Tumour undergoing Fatty Degeneration. Mr. Bowreman Jessell: A New Method of performing Abdominal Hysterectomy with five successful cases.

FRIDAY.

LONDON POST-GRADUATE COURSE, Bacteriological Laboratory, King's College, 3 to 5 P.M.—Professor Crosse: Lecture: The Microscope and Methods of Cultivation. Practical Work: Examination of Cultivations.

CLINICAL SOCIETY OF LONDON, 20, Hanover Square, W., 8.30 P.M.—Introductory address by the President, Papers.—Mr. Archibald Lane: Three cases of Extension of the Temporo-Maxillary Articulation in Children. Sir Dyce Duckworth: A case of Sudden Death due to Cardiac Syphiloma. Mr. Barker: Traumatic Derangement of the Knee-Joint due apparently to Fracture of the Spine of the Tibia; Exploratory Arthroscopy. Dr. Radcliffe Crocker: Impetigo Contagiosa Gyrata.

SATURDAY.

LONDON POST-GRADUATE COURSE, Bethlem Royal Hospital, 11 A.M.—Dr. Hyslop: Hysterical and Delirious Mania.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 2s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

MICHAEL.—On October 1st, at 18, Harold Terrace, Dover, the wife of Surgeon-Major H. J. Michael, A.M.S., of a daughter.

SMILT.—September 29th, at 371, Holloway Road, N., the wife of C. A. Casterton Smilt, M.B., C.M., of a son.

WHITAKER.—September 28th, at Cove House, Sandycove, co. Dublin, the wife of J. Minchin Whitaker, L.R.C.S.E.P.Ed., of a son.

MARRIAGES.

BALLANCE-MAUNSELL.—On September 28th, at All Saints Church, Raheny, co. Dublin, by the Rev. Alexander Thomas, M.A., Rector of Nenagh, brother-in-law of the bride, assisted by the Rev. F. Carlisle Hayes, M.A., Rector of Raheny, and the Rev. W. Smale, M.A., Vicar of St. Philip's, Kensington, Herbert Stanley Ballance, M.D., B.S.Lond., of Weston-super-Mare, third son of the late Charles Ballance, of Clapton, Middlesex, and of Mrs. Ballance, of 68, Fallowes Road, London, N.W., to Kathleen Isabella, daughter of John Maunsell, Esq., J.P., of Raheny, co. Dublin.

FRIED-HOWARD.—On September 28th, at St. John's the Divine, Kennington Park, by the Rev. S. R. Davies, Frederick Arthur Field, M.R.C.S., L.R.C.P.Lond., of Friern Lodge, Lordship Lane, S.E., to Emma, daughter of the late Edward Howard, of York, and granddaughter of the late Captain Clark, of Whitley.

FINDLAY-FALSER.—At Bombay, on September 28th, Harry Findlay, M.B., B.S., Rangoon, to Mary Lilla, daughter of the late J. B. Falser, Fort Edward, U.S.A.

GIBSON-LUTTON.—On September 26th, at Gosforth Parish Church, by the Rev. W. Maddison, M.A., Charles Gibson, M.D., Harrogate, to Ann Frances, younger daughter of Banister Lutton, of Becheroff, Gosforth, Northumberland.

WERN-CLARK.—On September 25th, at the Parish Church, Cheshire, by the Rev. F. A. Masdon, M.A., Rector, assisted by the Rev. S. Gauden, of Coal Island, co. Tyrone, Frank Webb, L.R.C.P., M.R.C.S., Newcastle, Staffordshire, son of James Webb, Brooklands, Cheshire, to Annie Louisa, second daughter of the late Leslie Clark and Mrs. Clark, Park House, Cheshire, Cheshire.

WILKS-KITTO.—On October 3rd, at St. George's, Bloomsbury, by the Rev. J. W. Goodall, M.A., Vicar of Titchill, Hotherham, brother-in-law of the bridegroom, assisted by the Rev. F. R. Boyan, M.A., Curate of the Parish, Joseph Henry Wilks, M.A., M.B., B.C., eldest son of Edward John Wilks, of Rutland Park, Sheffield, to Amy Kate Margaret, second daughter of the late Richard Luke Middleton Kitto, of Preston Lodge, Prestonpans, and formerly of Fryerstown, Victoria, Australia.

WORLEY-LEAF.—On October 2nd, at St. Thomas's Church, Pandleton, by the Rev. Canon Nunn, M.A. (niece of the bride), assisted by the Vicar, the Rev. J. E. Gull, M.A., and the Rev. G. Whithouse, B.A., Philip Worley, M.R.C.S., L.R.C.P., of Thornhill, Pandleton, son of Philip Worley, Her Majesty's Inspector of Schools, to Violet Elise, second daughter of the late Alfred Leaf, Esq., Solicitor, Leaf Square, Pandleton.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notices to be taken of their communications should authenticate them with their names—of course not necessary for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

PATERFAMILIAS asks for information as to the climate of Tunbridge or Tunbridge Wells, with special reference to its suitability in the case of a boy with bronchitic troubles, tendency to take cold, etc.

H. H. wishes to know whether patients unable to pay, or only able to pay a very little, are taken in at the Holloway Sanatorium, what are the cheapest terms there, and whether there is a similar institution where non-paying mental cases are taken in.

"S." Dr. S. R. Philipps, of the Holloway Sanatorium, informs us that the committee do, under exceptional circumstances, take in patients gratuitously, there being at present sixteen such on the books. The ordinary rate is 29s. per week, which is reduced in deserving cases to 28s. per week. Bethlem Hospital receives a large number of free cases. It is endowed, whereas the Holloway Sanatorium is without endowment, and has to be self-supporting.

SURGEON-MAJOR writes: I should be glad if any of your readers can suggest an apparatus for keeping in position the partially dislocated metacarpal bone of the thumb on the trapezium. The bone slips backwards and forwards in the trapezium with the most annoying freedom, being reduced and displaced again to the extent of about 1/4 inch. Various kinds of splints, pads, strapping, and plaster-of-paris have been tried without success. Curiously enough this is the second case I have had of the sort lately. In each the original displacement was very slight, produced by no very great force, easily reduced but difficult to retain in position.

"GOLF ELBOW."

ENQUIRER would be glad to know what is meant by "golf elbow," and what is the treatment most approved of?

WARTS ON THE HEAD.

G. M. writes: Are warty growths on the head common? I have a case where a crop appeared in a few days. They are of all sizes. What is the treatment other than glacial acetic acid as a local application and sulphate of magnesia internally?

SHIP'S SURGEON.

C. M. B. asks where he can get complete and reliable information of the duties and emoluments of a ship surgeon, and how to set about obtaining such a post. Some well-known agents informed him that if he would give his services as surgeon to a vessel for the outgoing journey to Australia, and also pay (not be paid) £20, they would provide him with a first-class saloon passage. The duration of the appointment, the vessel, and the company, etc., are immaterial, but a certain amount of salary, however small, is essential.

MECHANICAL ROAD CARRIAGES.

S. E. desires to obtain information as to mechanical road carriages such as were tried recently between Bordeaux and Paris.

"A." We believe that such carriages cannot, practically, be used in this country until the law has been amended. It is hoped that the Government will pass an amending Bill next session.

MANUAL OR ORAL INSTRUCTION FOR THE DEAF AND DUMB.

SURDUS asks: What is the consensus of professional opinion on the question of the superiority of the "manual" method over the "oral," or vice versa, in the instruction of deaf and dumb children? Is either system better than the other, or would it be best (for a school board, for instance) to adopt a system which shall be a combination of the two?

PURCHASE OF SHARE IN PRACTICE.

CLEARMONT asks whether the purchase of a share in a practice is usually based on gross receipts or on net profits? Is it also usual to purchase a further share (that is, to a moiety) on a basis of gross receipts or net profits, or is this arranged by mentioning a lump sum in the deed of partnership on payment of which the junior partner is admitted to a moiety?

*. The sale and purchase of practice is always based upon gross receipts. The succession to a further share should be secured, and as the point requires a careful adjustment, the best course would be to consult an expert.

A PROFESSIONAL GOVERNMENT.

N. writes: "P. M. O." addressing you in the *BRITISH MEDICAL JOURNAL* of March 24th, 1893, p. 571, asks for a reclamation from the Act of Parliament empowering medical officers and barristers in Indian Government Service to take fees. Here are the passages from the Act with introductory and explanatory remarks. The celebrated Regulation Act of 1773, 13 Geo. III, c. 63, after forbidding the acceptance by any civil or military officer of "any present, gift, donation, gratuity, or reward, pecuniary or otherwise," from any of the Indian princes or any other natives of Asia, enacted as a proviso s. 25: "Provided always and be it further enacted by the authority aforesaid that nothing herein contained shall extend or be construed to extend to prohibit or prevent any person or persons who shall carry on or exercise the profession of a counsellor, a physician, or a surgeon, or being a chaplain from accepting, taking, or receiving any fees, gratuities, or rewards in the way of their profession."

About 20 years after, another Act was passed to continue the Government of India by the East India Company, namely 33 Geo. III, c. 52. After very stringent provisions against the acceptance of gratuities, which is made a misdemeanour and after causing the gift to be forfeited to the Crown unless returned to the giver. The above proviso is repeated with slight alteration to make the meaning clearer. S. 64 declares: "Provided always and be it enacted that nothing herein contained shall extend or be construed to extend to prohibit or prevent any person exercising the profession of counsellor-at-law, physician or surgeon, or any chaplain from accepting, taking, or receiving fees, gratuities or rewards (bond fide) in the way of his profession only." This is still the law in India. The italics are mine.

ANSWERS.

HALIFAX.—We see no objection to the extracts forwarded.

F. S. L.—The suggestion is absurd, and it is idle to discuss the supposed reasons for a non-existent phenomenon.

GEMMA might consult the information as to clinical hospitals given in the Educational Number of the *BRITISH MEDICAL JOURNAL* (September 7th, pp. 604-607).

WEST AFRICAN MEDICAL SERVICE.

I. P. M. will obtain every information regarding the Army Medical Service on the West African coast by applying to the Director-General, Army Medical Department, 15, Victoria Street, Westminster, S.W.

FLKA BITES.

D. writes to recommend "Clinic" to prescribe for his patient the ordinary soap liniment of the *British Pharmacopoeia*. This soap liniment, applied here and there to the surface of the skin, acts both as a preventive and a destroyer of fleas. The odour of the liniment is only perceptible to bystanders for a few minutes only after the application, so that the patient is not obnoxious to his friends. On the other hand, the good effect, as regards the fleas, lasts for six or eight hours. The liniment requires to be simply smeared on the skin; it is not necessary that it should be rubbed in.

AGRICULTURAL LABOURERS' CLUBS.

ALPHA.—If the Society in question is desirous of changing its medical officer, and with that object gives notice of a fresh election, our correspondent would be quite justified, especially under the circumstances he describes, in becoming a candidate for the appointment, but it would be decidedly unethical on his part personally to agitate for any change or to encourage any section of the Society to do so on his behalf, because his residence happens to be more conveniently situated to meet the wants of a certain number of the members. We are disposed to think that agricultural labourers could at least pay twice a week a member, but are aware that as a matter of fact they pay less than this in most parts of the country.

NOTES, LETTERS, Etc.

VACCINATION AND WHOOPING-COUGH.

MR. THOMAS KINFAR, Public Vaccinator, (No. 1 South City District, 1-43th), writes: In the *EPITOME* of the *BRITISH MEDICAL JOURNAL* of September 24th, par. 256, I see a note by G. Cavillieri (*Pres. d. Oped.*, June 1895) stating that he had tried the effect of vaccination in cases of pertussis, and found that it cut short the disease in from three to three and a half weeks. Some time ago, within the last five years, I think—I cannot be certain as I have not the *JOURNAL* to refer to—I wrote stating that some years previously I had seen in some American medical paper an account of the beneficial effects of vaccination in cutting short the course of whooping-cough in children suffering from that disease who were unvaccinated, and that I had tried it and found that such was the fact, and that my practice was to vaccinate all such children coming under my observation, with the result that I found the disease was cut short, and that the whooping-cough was cured in a very short time, and without any ill-effect on the child.

In the next issue of the *JOURNAL*, or very shortly afterwards, I was considerably taken to task by a contributor to your paper, who held me up to ridicule. I have nevertheless continued to vaccinate in all

cases of whooping-cough where the subject was unvaccinated with the happiest results. In no case that I can call to mind has the whooping-cough not been cured in three weeks after vaccination. Vaccination does not appear to have any effect on the disease if the patient has already been vaccinated before the whooping-cough appeared, but otherwise I am satisfied that it is of decided use in cutting short the disease.

THE CONTAGION OF SCARLET FEVER.

MR. W. KENNEDY (Waterford) writes: In a letter dated September 2nd Dr. E. S. Gilbert stated that "for the last twenty years he has acted on the conviction that in a desquamating skin after scarlet fever there is no danger to others," but that "during the isolation period (one month) he has the skin smeared daily with carbolic oil," and finally washed with "three good scrubblings of hot soap and water." Now if he acted consistently he would discard these precautions as waste of energy, but his twenty years' conviction would shortly after receive a shock from which it would never recover, and he would realize that there is a vast difference between those desquamations which have, and those which have not, been systematically disinfected before their separation from the body of the patient.

NERVOUS PYREXIA IN A CHILD.

MR. FRANCIS W. RILEY, M.R.C.S. Eng., L.R.C.P. Lond. (Liverpool), writes: In the spring of this year I was summoned to see a girl, aged 11, who hitherto had enjoyed good health; she had had scarlet fever and measles some years previously. On the afternoon of the day before I was called in the child had been vomiting greenish matter, and was unable to take her food. The mother put the patient to bed and kept her quiet. During the night the child was very feverish and delirious. The mother mentioned that the previous afternoon the child had come running into the house crying that one of the neighbours was threatening her with a knife. In her delirium she was calling out that a woman was running after her with a knife, and that blood was streaming down her back.

On first seeing the child I suspected one of the specific fevers, but found no evidence in favour of this supposition. The lungs and heart were normal, and the only evidences of any disease I could find were a temperature of 103°, some very slight congestion of the tonsils, and precordial pain, but no lesion to account for it. I prescribed salines, diaphoretics, a dose of castor oil, and light diet.

On the following day (Friday) the patient was in much the same condition; I therefore gave 5 grains of quinine, but it had no appreciable effect, for the following day the temperature was still above normal, though it had fallen to 101.2°. On this day (Saturday), as the child was getting very low and rapidly losing strength, I ordered brandy. The next day (Sunday) the condition had slightly improved, and the temperature was 100°. On the Monday I found the patient had evidently taken a change for the better; the temperature was 99.5°, and the condition was more favourable.

About a week after the child first commenced to be ill I paid a visit to my patient, and found her up and going about in the usual way. I saw the child several times after this, but she was apparently restored to perfect health.

In this case I think the pyrexia was undoubtedly due to nervous origin, through the fright the child had had. Of course there must be some reserve in putting this case down for pyrexia in children, for in them we are always confronted with some diagnostic difficulty when we find in their cases high temperatures, for very slight organic troubles such as errors in diet may tend to pyrexia in children, whereas in adults we should find very little disturbance. But as I inquired into every possible cause for the febrile condition, and made repeated careful examinations of the case from all points, I feel in my own mind that this was a case of nervous pyrexia.

RAPID DIAGNOSIS.

To diagnose patients at the rate of two and a half a minute seems, says the *Westminster Gazette*, pretty quick work. According to a German contemporary, this is about the average performance of Pastor Kniepp, of cold water fame, at Woerrichshofen. When receiving patients on a busy day the pastor sits at a long table in a large, plainly furnished room, smoking a huge cigar. He dictates his "prescriptions" to an assistant in a solemn tone, as if he were presiding at a religious ceremonial. Men, women, and children of every station in life file past him. In an hour and a quarter he gets through 150 without difficulty. There is no examination and few questions are asked—indeed, there is little necessity, for cold water baths and bandages and walks on wet grass with bare feet exhaust the worthy pastor's pharmacopoeia. There is one exception: an ointment composed of honey and medicinal herbs for those who suffer from diseases of the eye. But then the ointment is a sovereign one for everything, and so Pastor Kniepp manages to break the record as an oculist as well.

THE QUESTION OF FEES.

M.B. M.R.C.S. Eng. writes: With regard to the questions of fees now so much discussed may I quote two passages from Bramshy Cooper's *Life of Sir Astley Cooper*? Vol. i, p. 272: "Soon after I got into my new residence," Sir Astley relates, "a patient gave me half a guinea, saying 'I gave Mr. Cline a guinea, but as you were his apprentice I suppose half a guinea will do for you.' Mr. Cline made it a rule to take whatever was offered him, so I did not refuse the proffered fee." Vol. II, pp. 205-2: "He (Sir Astley) never spoke of a fee in his life, when he received one he made it a rule to regard the case as one of disaster, and was glad to perform an office of charity. 'If we receive more than we expect,' he has often said, 'we return nothing; why, then, should we complain on receiving sometimes less than we deserve?' Even at the period of his life when his days were increasingly occupied by the demands of his public and private practice he would spend the greatest part of his nights in dissection, and it was then well known that he was ready at any hour to obey a summons from any quarter to attend a patient."

Is there any need for the members of that great College which owned Sir Astley Cooper, Sir Richard Owen, and Mr. Huxley to desire any

further title than that prefixed to the name of John Hunter. Plain Mr. John Hunter's name will never die. Perhaps the public would think more of us if we did not assume titles to which we have no title of our own assurance. Probably they would pay us better also.

Is a Quack another Quack? In vol. L. p. 455, there is an extract from the *Antony Cooper's* judgment of himself. "The diagnosis was most remarkable. He obtained that decision from having made it a practice when young to see all the poor who would come to him, and to see how such a variety of disease as to make him as familiar with it as a parent with his child. His principle in practice was never to suffer anyone who consulted him to quit him without giving them satisfaction on the nature and proper treatment of their case." Free admission on the part was not "unprofessional conduct" then. But I beg to say that straighter and harder honesty of the old surgeon that raised him as high in the opinion of his contemporaries last when a quack sat up in the borough and took the name of "Dr. Antony Cooper" the surgeon did not think it worth his while to notice so palpable a fraud.

BURIED ALIVE.

X. Y. Z. writes: In view of the sensational letters on this subject in the daily papers it is well to be sure of our ground. The whole question resolves itself into this: "How far can cataplexy simulate death?" I have always looked upon loss of tension in the eyeball from relaxation of the elastic tissue of the cornea as an absolute test of death. May I ask if any of your readers who are acquainted with cataplexy have ever seen or heard of a case of cataplexy in which this condition has been simulated?

A CENTENARIAN.

F. R. C. P. writes: As you refer to Mrs. Nave in your article on centenarians in the *British Medical Journal* of September 21st it may interest your readers to know that, what in consequence a fortnight ago, I had the pleasure of an interview with this truly wonderful old lady, who received me most kindly. She walks easily without the assistance of anyone, and with her glasses could comfortably read her prayer book, which was printed in nonpareil type. Her conversational powers are remarkably good, and though slightly deaf at times she has no occasion for the aid of an ear trumpet or the like. She talks and acts more like a woman of 63 than one who was 103 in May last, and her appearance would give a stranger no idea of her advanced age. Though, in different parts of the world, I have been fortunate in meeting very aged people of both sexes (one old man in Quebec that I spoke to had attained his 100th year), yet no one has hitherto impressed me so much as did Mrs. Nave, whom I am sure all your readers will join me in hoping that she may yet enjoy (if in her present sound health) many years of life in the beautiful island in which she has so many years resided.

ENTERIC FEVER AT POONA.

THE death of Captain Upperton, A.D.C. to General Blundell, from this disease quite recently, draws attention to the report that at a Cantonment meeting Brigade surgeon-Lieutenant-Colonel MacKury made a strong representation as to the insalubrious state of the Poona cantonments, and pointed out the probable sources of prevailing sickness. Several young soldiers have died during the past few weeks of enteric fever.

YET ANOTHER ISHERHURST CURE.

AN amusing account of the examination of a number of reputed drunkards who claimed to have had the drink craving destroyed by a secret "vegetable cure," has been given by a provincial daily journal. A goodly proportion of the persons experimented upon reported that they had kept from liquor and had no desire for it. How long can drunkenness survive if the hundreds of "cures" which have been certified by abstaining and non-abstaining philanthropists to have been equally successful are to be augmented by another new "cure" almost weekly? It is surprising that the much more numerous temporary—in some instances permanent—conversions to abstinence which have repeatedly characterised epidemic waves of temperance in America and Britain have been passed by without notice, and yet that a similar alleged result is certified and applauded when stated to have been obtained by the hourly swallowing for three weeks of a proprietary "cure."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	20	4	0
Each additional line	0	0	6
A whole column	1	17	6
A page	5	5	0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

SIXTY-THIRD ANNUAL MEETING
OF THE
BRITISH MEDICAL ASSOCIATION.

Held in LONDON July 30th, 31st, and August 1st, 2nd, 1895.

PROCEEDINGS OF SECTIONS.

SECTION OF SURGERY.

Sir W. MAC CORMAC, F.R.C.S., President.

The Presidential Address, delivered by Sir W. Mac Cormac, will be found on page 278.

DISCUSSION ON THE DIAGNOSIS AND TREATMENT OF FRACTURES OF THE UPPER THIRD OF THE FEMUR, INCLUDING THE NECK.

I.—SIR WILLIAM STOKES, Ch.M.Univ.Dubl., F.R.C.S.I.,
Surgeon in Ordinary to Her Majesty the Queen in Ireland; Professor of Surgery, Royal College of Surgeons, Ireland, etc.

THE first subject which has been selected for discussion by the Council of the Surgical Section on the present occasion may not possibly have the same attractions as one more closely identified with recent surgical development, as, for example, the surgery of the brain, the thorax, or the renal organs. It is desirable, however, in the interests and advancement of our art, that the surgical student, as well as the student of sculpture or painting, should at times look back, contemplate, and study the work of his predecessors, observing how much has stood the test of time and experience; and in some instances noting perhaps how rash it is to generalise from insufficient data, while observing that what remains permanently accepted is the result of no mere chance discovery, but of long, careful, and accurate observation. Some time ago the opinion was expressed to me by a surgical friend of ability that the amount of brain power that has been expended in attempting to form an accurate estimate of the diagnostic signs and symptoms attending certain bone lesions, notably fractures and contusions of the lower end of the radius, of the fibula, and of the upper third of the femur, by what he considered to be an unnecessarily close investigation of minute pathological variations, is quite in excess of the importance of the subject, considered either in a practical or scientific point of view. In this opinion I could not concur, holding that so long as the dense mists which still unhappily obscure many of these injuries, especially those of the cervix femoris, rendering it often difficult, in truth well nigh impossible, to estimate and differentiate with exactitude the protean forms of injury that are met with there, so long will it be necessary to continue the system of accurate investigation and close analysis, of which such signal examples have been given us by the splendid work in this direction of Sir Astley Cooper, A. Colles, Dupuytren, Malgaigne, R. W. Smith, Adams, Humphry, Bryant, Gordon, and others.

It should ever be borne in mind by those disposed to make little of such investigations that, if a subject is worth working out at all, too minute a consideration cannot possibly be given to it; and this would especially apply to the practical aspect of the topic to be discussed to-day, as there are few injuries, or groups of injuries, in which accuracy of diagnosis is more important or more imperatively called for. I am not vain enough to hope that any remarks I may make to-day will materially advance our knowledge or much increase our powers of differentiating the characteristic signs and symptoms of these injuries, and it seems to me my function on the present occasion should be mainly to point out the limits that have been reached, and some of the principal landmarks that have been given for our guidance, trusting that those

who follow me may erect others, by which we may hope to advance further.

From the preceding remarks it may, perhaps, be thought that as regards difficulties of diagnosis I have given too gloomy a picture of the situation; that I regard it somewhat in the light of an impenetrable jungle in which reliable landmarks are still wanting. When we remember, however, that in these injuries at times many of the signs and symptoms of fracture may be present without the occurrence of any such lesion, and that, on the other hand, fractures may exist without many of these signs and symptoms, it should hardly, I think, be considered that I have expressed myself in any exaggerated manner. There is, in truth, no group of fractures in the vicinity of a joint in which there is greater variation in the signs. In the majority of cases there is more or less shortening of the limb, in others it is scarcely perceptible, and in one form it has been said that even slight lengthening may occur. In most cases there is eversion and abduction of the limb, but in others there is neither one nor the other, and in a third group there is inversion and adduction. In some there is pain, and in others a comparative freedom from it. Immediate shortening of the limb occurs as a rule in fractures of the cervical base, but it frequently happens in fractures of the cervix that it is a subsequent secondary development. In fractures of the base impaction occurs in some cases and is absent in others, whereas in the cervix proper we have, as I think, not impaction but penetration. In some instances the fracture is the result of a fall, and in others the fall is the result of the fracture. In one group exuberant new bone growths are the rule, whereas in the other absorption of bone is usually observed. Death from

Fig. 1.—Fracture with exuberant bone growth.

hemorrhage in fractures of the base has been noted by Cruveilhier, R. W. Smith, Vidal, and others, but I am not aware that it has been observed in connection with fractures of the cervix. Communion is a frequent complication in one group, but is rarely if ever observed in the other. Fractures of the cervix are met with as a rule in the more advanced periods of life, although rare cases, such as that shown in Fig. 3, p. 882 for which I am indebted to Mr. Bland Sutton, and which is taken from a specimen in the museum of the Middlesex Hospital, prove that they may be met with even before the junction of the epiphyses. Some-what similar cases have been observed by Morgagni, Stanley,

and Hamilton. Lastly, the more serious of these injuries, both as regards immediate and remote consequences, is often the result of trivial force indirectly applied—a greater force as a rule producing the less serious fracture.

Fig. 2.—Fracture with absorption of cervix.

All these circumstances tend to prove the truth of R. W. Smith's dictum, that "each particular symptom of fracture of the neck of femur separately considered must be looked upon as equivocal; the union of all can alone lead to the formation of a correct opinion as to the nature and seat of the injury."

Fig. 3.—Fracture of cervix before union of callus.

Before discussing any of the points connected with the

classification or differential diagnosis of fractures of either the cervix or its base, I should like to say a few words in reference to some anatomical details which are called for, having regard to the fact that one structure in the joint, and that in my opinion the most important in a surgical point of view, is in many, indeed most, of the modern surgical textbooks practically and strangely ignored. I allude to the fibro-synovial envelope of the cervix, to which attention was, I believe, primarily given by the late Mr. Stanley, and my former master, Professor R. W. Smith, the so-called cervical ligament, with which I think their names might properly be associated. In a case of fracture of the cervix, it is not too much to say that on the integrity or otherwise of this ligament the outcome of the case mainly depends.

Being an important medium, through which nutrition is supplied to the bone, in most instances already modified by senile changes, if not in its form, in its structure, any injury, such as severe contusion, laceration, or tearing, is certain to be followed by serious consequences, such as inflammation, effusion into the joint, displacement, shortening, non-union, and ultimate atrophy. Its osteogenic properties appear to exist in a very limited degree, and it is covered or lined by what appears to be an exceptionally sensitive synovial membrane. In its fibrous structure there is no uniformity as regards thickness and strength, for in some situations, especially in front, the strong bands can be observed, the "retinacula" of Weibrecht, thus resembling the capsular ligament of the joint, which is so strengthened on its anterior surface by Bigelow's Y-shaped ligament.

The consideration of these facts is a matter not merely of theoretic, but of practical interest, for it is by observing what occurs when the integrity of this ligament is maintained that we are furnished with an index as to the line of treatment we should adopt in cases where it is not so preserved. Upon the latter circumstances depends largely the remarkable variation in the physical characters of fractures of the cervix, as much as the sequelae of such injuries. Among these, one of the most remarkable is the rapidity and completeness in the interstitial absorption of the cervix, which takes place not alone in cases of fracture, but also in cases where there is no evidence of such having taken place, but only of contusions such as are familiar to everyone who has even made a superficial study of these injuries.

This rapid absorption may be due primarily to senile alteration in the bone tissue, and secondarily to activity of absorption due possibly to traumatic disturbance. It seems to illustrate the fact that in morphological changes the osseous system is one of the most plastic. As an example of this I would point to the readiness with which bones are absorbed owing to the pressure of aneurysms and other tumours, showing that a system which at first sight would seem so much more capable of resistance than other structures, is as a rule, the first to break down.

Of this condition of absorption many signally beautiful examples are now before us. Mr. Curling¹ has discussed this point exhaustively. He has pointed out that in the majority of fractures within the capsule, "the periosteum being torn, the circulation is diminished to a greater extent than in other descriptions of fracture, where one division of the bone is deprived of its nourishment from the medullary arteries. The loss, moreover, is not limited to its central structure, but the whole of the detached bone sometimes suffers, and the atrophy, instead of being merely eccentric, occurs throughout its texture—not only the cancelli enlarging, but the size of the head becoming insufficient to fill the acetabulum."

A similar process may, I think, result from impaired nutrition, consequent on synovio-periosteal inflammation without fracture. Certain it is, I think, that many cases have been noted in which atrophy of the cervix occurred without fracture, and was not only a source of error in diagnosis, but also the cause of blame being unjustly attached to the surgeon for not recognising the occurrence of a supposed fracture, the disappearance or diminution of the neck producing many of the apparent signs of fracture.

¹ *Med.-Chir. Trans.*, vol. xx, p. 336.

The process of atrophy and absorption which goes on in these cases is similar, as Curling pointed out, to the thyroid atrophy which takes place following the ligation of one or more of the thyroid arteries or division of the isthmus. The atrophy is essentially eccentric, the cancelli and medullary cavity enlarge first, and this is followed by a thinning of the outer shell. In some instances the cartilaginous parts are first removed, and the head of the femur sinks down upon its shaft, but "more commonly the texture remaining is brittle, and the bone gives way on receipt of even a trivial force."

This process of rapid absorption is, in the case of fracture, probably due, in the first place, to senile osteoporosis; and

Fig. 4. - Senile osteoporosis.

in the second place to the twofold action of the absorbents on the one hand, and friction of the broken fragments on the other; and in the case of contusion, to impaired nutrition, consequent on a low form of synovio-periosteal inflammation.

Until recently the generally received opinion, and one accentuated by R. W. Smith, was that an alteration in the angle between the axis of the cervix and the shaft was a frequently observed senile change, this being held to be one of the determining causes of fractures of the cervix in advanced periods of life. The researches, however, of Sir George Humphry, and also of Dr. Charpy, of Lyons, have definitely disposed of this view. According to the latter, the angle between the axis of the cervix and the shaft is in the infant greater than in that of the adult; but once adult life is reached, no further change in the angle is observable. There can be no doubt that an alteration in the angle has been observed in old femora, and a signal example of this is to be found illustrated in Professor Gross's work on surgery; but this is, I believe, due, not to any normal senile change, but to a partial absorption of the cervix, probably from contusion, which has ultimately the effect of approximating the head to the shaft of the bone. It has been held by those maintaining the theory of senile alteration in the angle that there is an analogy between this and what, as everyone knows, takes place in the lower jaw. There is, however, nothing of the kind. In the case of the lower jaw, as Sir George Humphry has pointed out, the angle between the ramus and the body of the bone is rendered more obtuse by the effect of muscular action, drawing the angle forwards and upwards, there being no opposition to this force, in consequence of the loss of the teeth and the absorption of the alveolus. The result is an obliteration of the acuteness of

the angle. No analogous process, of course, occurs at the junction of the cervix and the shaft of the femur.

It may therefore, I think, be held as tolerably certain that we cannot connect, as so many have done, the frequent occurrence of fractures of the cervix in aged persons with any normal senile alteration in the angle between the axis of the cervix and the shaft.

Fig. 5. - Fracture of cervix with penetration of cervix into head.

As regards the many forms of fracture of the cervix femoris that we have to deal with, the varying position and limit of the capsule posteriorly, together with the fact that a large proportion of these fractures are, so to say, mixed—that

Fig. 6. - Fracture of cervix with reciprocal penetration.

is, partly within and partly without the capsule—sufficiently justify, I think, an abandonment of the classification adopted by Sir A. Cooper, R. W. Smith, Adams, and others, into intra- and extracapsular fractures. But although this classification may be anatomically or pathologically incorrect—"unscientific," as Mr. Bryant terms it—in a clinical point of view it is convenient, and, as far as this aspect is concerned, might be retained. In the accompanying scheme I

Fig. 7.—Fracture of cervix at junction with head.

have indicated in a tabular form what I think should be the accepted classification, adopting many of the subdivisions of intra- and extracapsular fractures suggested by the late Professor Gordon, of Belfast. In considering the subject of

Fig. 8.—Fracture at centre of cervix.

classification, I think it is desirable that a distinction should be made between fractures with and without penetration, and fractures with and without impaction. A similar distinction has been made by Professor Chiene in connection with fractures of the lower end of the radius, and I think it can with equal propriety be made in connection with fractures of the femoral neck or its base. Those within the capsule afford examples of the first group, those external to it the second. In

Fig. 9.—Fractures of cervix with laceration of cervical ligaments and absorption of cervix.

reference to this classification I may mention that the majority of illustrations I desire now to submit to your consideration are from specimens belonging to the Museum of the Queen's College, Belfast, and I am indebted to the kindness of the distinguished Professor of Surgery there, Dr. Sinclair, for enabling me to exhibit them.

Fracture of Cervix Femoris (Intracapsular).

| IV. Fracture of base with partial impaction below (shaft split) | |
| V. Longitudinal splitting of cervix | } Without impaction. |
| VI. Comminuted fracture without impaction | |

Among the fractures of the cervix there can be no doubt that the fifth variety is the one that is most frequently met with, and the one in which osseous union, owing to deficient nutrition, non-apposition of the fragments, synovitis, effusion of blood, and rapid interstitial absorption, never takes place. The frequent occurrence of this result it doubtless was, that caused Sir A. Cooper, Cruveilhier, and others to fall into the error of maintaining that osseous union never takes place in intracapsular fractures. Now we know that in a considerable

proportion of these cases osseous union does take place, and before us we have many beautiful examples of this taken from the Museums of the College of Surgeons here and in Dublin, the Museum of the Royal University of Ireland, and that of the Queen's College, Belfast, and I here tender my

Fig. 10.—Fracture of base of cervix, partial impaction posteriorly.

grateful thanks to the authorities of these institutions for enabling me to submit, for the inspection of the members of the Association, the superb collection of specimens of these injuries which is now before them. There are two conditions

Fig. 11.—Fracture of base of cervix with complete impaction.

which appear to be essential to the occurrence of osseous union—one, the integrity of the cervical ligament; and the

other, the existence of one of the two forms of penetration, either (a) of the cervix into the head, or (b) reciprocal penetration. It would appear, therefore, that there are four different forms of fracture of the cervix in which osseous union may take place, provided the routine expectant treatment be abandoned.

Fig. 12.—Fracture of base of cervix, partial impaction below (shaft split).

It may, I think, also be held that the further from the base of the cervix the lesion is, the less is the chance of

Fig. 13.—Fracture of base of cervix, longitudinal splitting of cervix. Osseous union. The nutrition of the bone at the base is not so profoundly affected as in situations nearer the head, since

in the latter it is derived chiefly through the medium of the cervical ligament, which is, as a rule, more or less torn or

the base of the neck upon the shaft, but few, I should think, would be disposed to accept this view.

Fig. 11.—Comminuted fracture of base of cervix without impaction.

contused. The osteogenetic properties, too, of the fibrous envelope of the cervix appear to be almost nil, and absorption of the bone, the nutrition of which is so much impaired, appears to be carried on with exceptional activity, not merely in cases of fracture, but also in those of contusion; and the difficulties of maintaining fixation and rest are more prominent owing, among other things, to the rarity of penetration which is observed the nearer the lesion is to the head.

In the second group, namely, the fractures of the cervical base, impaction in some form or other is the rule, and the amount of eversion which is present in almost all cases depends on the particular form of impaction that has occurred. The most usual is of the posterior cervical wall into the cancellous structure underneath the posterior intertrochanteric ridge, and the probable reasons why the posterior wall is so much more frequently impacted than the anterior are anatomical and mechanical. Among the former may be mentioned the capsular ligament being strengthened anteriorly by the powerful Y-shaped ligament, also by the retinacula of Weitbrecht being broader and stronger in front than behind, and the compact tissue of the cervix being thicker anteriorly than posteriorly. Again, when a person falls on the trochanter the point of impact lies, as a rule, behind the axis of the neck, and this would obviously predispose to posterior penetration.

In the second form the direction of the force is either in a line with or in front of the cervical axis; and in the third form Gordon held that by the accidental downward inclination of the ground on which the patient falls the greatest amount of shock is communicated to the upper part of the neck, resulting in impaction of the neck above and increase of the obtuseness of the angle, and in the fourth form, owing to the lower part of the base receiving the greatest amount of shock, and the base being particularly dense at this part, the shaft is split.

There is little difficulty in understanding the characteristic eversion that is observed in the vast majority of cases of fracture, either of the cervix or its base, due, as Bigelow held, to a rotation of the fractured bone on a hinge formed in the anterior cervical wall. The theory of eversion being due to rotation of the shaft upon the base of the neck is, according to some, untenable, who hold that it is due to a rotation of

Fig. 12.—Rare form of fracture of the femur.

The occasional occurrence of inversion in both groups of fractures of the cervix and its base is more difficult of explanation, and is a sign which in no small degree adds to the difficulties of differential diagnosis. Guthrie held that this unusual condition was confined to the extracapsular forms

Fig. 13.—Rare form of fracture of the femur.

of fracture, the one, namely, through the great trochanter, a portion of it being continuous with the shaft of the bone: but this has been shown to be erroneous, as the condition has been observed in the fractures of the cervix within the

capsular ligament. The late Professor Pirrie published a very remarkable case of extreme adduction, flexion, and inversion of the limb in a case of fracture of the cervix close to the head, at right angles to the axis of the neck. The patient died six weeks afterwards. The capsular and ilio-femoral ligaments were found uninjured, and to the integrity and tension of these ligaments Professor Pirrie attributed the adduction, flexion, and inversion of the limb. It is hard to understand, on anatomical grounds, how the inversion could be explained satisfactorily in this way.

Fig. 17.—Isre form of fracture of the femur.

R. W. Smith held the view that the inversion was due to the altered action of the adductors, which became rotators inwards, owing to the lower fragment being displaced in front of the upper, so that the insertion of these muscles was in a plane anterior to their origin. If muscular action was the cause, however, the inversion would continue constant; but such is not the case. I can call to mind a case in which inversion was well marked, and a day or two afterwards I found that the usual eversion had supervened. I think, therefore, the inversion is most probably due to the limb having been adducted and inverted at the time of the accident, and that afterwards the limb remained in the position it was at the time injury was sustained.

No part of this subject is of greater importance than the differential diagnosis, as the patient's future and the surgeon's reputation depend on a correct estimate of this being formed. The conditions with which fracture of the cervix or its base may be mistaken are luxation on the dorsum ilii, fracture of the brim of the acetabulum, fracture of its fundus, and contusion. The differentiation may as a rule be correctly made by bearing in mind that, whereas in fracture we have usually a history of a direct fall on the trochanter, followed by eversion, shortening, and backward direction of the outer surface of the trochanter, occurring in advanced life, and with marked pain along the line of fracture, diminished tension of extensor muscles, occasional inversion, and that not well marked; in luxation, on the other hand, we have a history of forced rotation inwards, rarity of occurrence in advanced life, usual inversion, great shortening, approximation of trochanter to anterior superior spine, head of bone on dorsum ilii, movements difficult and restrained, absence of pain on trochanter, increased tension of extensor muscles, and constant, well-marked inversion. In fractures of the brim of the acetabulum we have the head drawn upwards and backwards, with detached fragment of brim, shortening, inversion, crepitus,

adduction, recurrence of shortening after extension is removed, and power of eversion and abduction of the limb. In fractures of the fundus we have usually comminution, head passing into the pelvis, shortening, liability to abscess formations, and generally a fatal result. In contusion we have a preservation of the normal relations between the anterior superior spine and trochanter preserved at first, but often ultimately lost, and the knowledge that pre-existing chronic rheumatism may in these cases accentuate the difficulty of differentiation in no small degree.

I have here tabulated these points of difference, and a reference to the leading signs and symptoms of them, grouped side by side, may facilitate our forming a correct diagnosis.

Differential Diagnosis.

Fracture of base of Cervix (Extra-capsular.)	Dislocation on Dorsum ilii	Fractures of the Brim of Acetabulum.	Fractures of Fundus of Acetabulum.	Contusion.
Common in advanced life.	Rare in advanced life.	—	—	Relation between anterior superior spine and trochanter on both sides the same at first. Pre-existing chronic rheumatism, a cause of great difficulty in forming a right estimate of the case. Note the previous history, and observe that the powerless state induced by the injury and passed off.
History of direct fall on trochanter.	History of forced rotation inwards of femur.	—	—	
Shortening.	Shortening greater.	Shortening occurring after extension is removed.	Shortening.	
Eversion constant.	Inversion constant.	Inversion.		
Inversion slight (marked).	Inversion well marked.	Power of eversion.		
Movements comparatively easy.	Movements difficult and restrained.	Adhesion.		
		Flexion of knee.		
Head to acetabulum.	Head on dorsum ilii.	Head drawn upwards and backwards with detached fragment of brim.	Head passes into pelvis.	
Outer surface of trochanter looking backwards.	Approximation of trochanter to anterior superior spine.	Crepitus.	Fracture comminuted, star-shaped.	
Pain along line of fracture in front, above, and behind.	No pain on pressure over trochanter.			Liability to formation of abscesses in iliac fossa.
Diminished tension of extensor muscles (Lagoria.)	Increased tension.			Accident generally fatal.

As regards the treatment of these injuries there is still much diversity of opinion. The employment of fixation and extension has been by many condemned as a useless and irrational practice on the grounds that as the trochanteric fragment is approximated and more or less fixed to the acetabulum by the obturators, gluteus minimus and pyramidalis, so by rotating the limb inwards and extending, the base of the neck is, as Professor Garden held, separated from the trochanter, posteriorly at all events, and the shaft from the head and neck. The fragments, in fact, are drawn asunder, thus diminishing the chances of osseous union. In addition to these alleged disadvantages there are those which undoubtedly attend keeping the patient, especially if advanced in years, for a considerable time in the recumbent position.

For these reasons the routine treatment formerly was a very simple one, consisting practically in doing nothing at all, the rule adopted being to let them (the patients) select their own position and support the limb in any way they pleased.

This simple but, as a rule, ineffective method of treatment is no longer, I think, generally accepted. Professor Senn instituted in 1883 a series of interesting experiments on cats and dogs, with the object of determining what will best promote the chances of osseous union in fractures of the cervix femoris. In a large proportion of cases, when the required conditions were obtained by drilling and subsequent fracture of the cervix, and when, in the after-treatment, nothing was done except to keep the limb in a gypsum bandage, there was no attempt even at the formation of bony union. In a second series of cases the treatment of a more thorough immobilisation was adopted by fixing, namely, the fragments with ivory, bone, or metallic nails. In ten of such experiments bony union was obtained in most of them. The ivory and bone nails were usually found absorbed, the metallic ones encysted. The importance of these experiments consists in demonstrating that the more perfect the fixation and immobilisation are, the greater is the chance of bony union, and the conclusion is irresistible that the surgeon should be cautious not to break down or disturb any penetration or impaction that may be present. Consequently, with the view of securing permanency of the impaction, Professor Senn has introduced the principle of making lateral pressure in the direction of the axis of the cervix by a pad which rests on the external surface of the great trochanter, and the necessary pressure made by a screw action, which can be regulated from day to day. In non-impacted fractures the fractured surfaces should be brought into perfect mutual apposition, and in this position the affected limb, pelvis, and thigh on the opposite side should be encased in a plaster-of-paris dressing, all of the bony prominences being well protected by salicylic wool. In this dressing Professor Senn combines the application of his splint, in which provision is made for the lateral pressure.

Some surgical authorities, Sir John Erichsen among the number, consider that in an extracapsular impacted fracture a limb cannot be restored by traction to its normal length, and that nothing can be done to diminish the deformity, the patient remaining throughout life more or less crippled. Recently there seems to be evidence of a tendency for the pendulum of surgical opinion to swing to the opposite side, for with the view of preventing or diminishing the permanently crippled condition that Sir J. Erichsen speaks of, Mr. Southam, of Manchester, has practised and advocated a deliberate breaking down of impaction, instead of leaving it intact as surgeons hitherto have aimed at doing. The patient whose case Mr. Southam has published,¹ was aged 27 years, and all the usual signs and symptoms of extracapsular fracture of the neck of the femur were present. The patient was anaesthetised, the impaction broken down, and the excision and shortening being overcome, the fracture was then treated by extension. "The fracture readily united with the limb in the corrected position, no deformity ensuing."

It is possible that in the treatment of this case Mr. Southam may be the pioneer, so to speak, of a revolution in the routine practice adopted in such instances. As far as one can judge from a single example I should say that the treatment could only be applicable in a very limited number of cases, namely, those rare ones that occur at a period of life long antecedent to that of any senile anatomical change, and when the physical reparative powers are in full activity. In no other case, I should imagine, having regard to the senile changes in the bones to which I have alluded, could the practice be adopted with any reasonable hope of success. I have pointed out that in four different varieties of fractures of the cervix (intracapsular) osseous union, and that with little or no deformity, can take place.

This satisfactory result is the result of one or other of two conditions being present, namely, penetration or the preservation of the integrity of the Stanley-Smith cervical ligament. When either or both of these conditions are present as well as the absence of any marked senile structural change osseous union may take place in consequence of the proper and permanent apposition of the broken ends of the

bone. Our object, therefore, should be to bring about this condition as far as is practicable by artificial means, and this can best be done by rest, fixation of the limb, and as much extension as will aid in promoting these two latter essential conditions. I have not as yet tested Professor Senn's method of lateral pressure, but in my experience the necessary conditions can best be fulfilled either by Mr. Bryant's double splint, or, I hope I may say without vanity, by the screw extension combination splint which I have devised and employed, not merely in the treatment of various fractures of the lower extremity, including those of the cervix femoris and its base, but also in certain forms of chronic articular disease. Whatever apparatus is employed, it should be remembered that two things are essential, especially in dealing with very aged persons: First, to have provision for enabling the patient to sit up occasionally, not allowing him to remain long in the recumbent position; and secondly, that the extension be not greater than will promote immobility; in other words, care should be taken not to have any violent and useless contest set up between muscular and mechanical forces, a condition necessarily antagonistic to, if not incompatible with, that rest, fixation, and freedom from pain which are so essential to the satisfactory union of all wounds, whether of bones or soft structures.

From the preceding considerations we are, I think, justified in forming the following conclusions:

1. The alleged senile alteration in the angle between the axis of the cervix and the shaft of the femur does not occur, and cannot therefore be regarded, as it has hitherto been, as a predisposing cause of fracture of the cervix femoris.
2. That the process of absorption in the case of fracture is probably due primarily to senile osteoporosis, and secondarily to the twofold action of the absorbents on the one hand and friction of the broken fragments on the other, and, in the case of contusion, of impaired nutrition consequent on a low form of synovio-periosteal inflammation.
3. That in classifying fractures of the cervix or its base a distinction should be made between those with and without penetration, and those with and without impaction.
4. That osseous union may take place in four out of the five different forms of fracture of the cervix femoris.
5. That the further the fracture is from the base of the neck, the less is the probability of osseous union.
6. That fracture of the cervix may occur previously to epiphyseal junction.
7. That the differentiation of these injuries lies between fracture of the cervix or its base, luxation, fracture of acetabular brim, of acetabular fundus, and contusion.
8. That the principles of treatment should be fixation, rest, and moderate extension.

II.—Sir GEORGE MURRAY HUMPHRY, M.D., F.R.S.,

Professor of Surgery, University of Cambridge.

SIR GEORGE HUMPHRY considered the conclusions arrived at by Sir William Stokes to be most important. He then proceeded to lay down as an axiom that a fracture in any part of the skeleton at any time of life will unite if the parts can be kept in contact. The senile change in the neck of the femur is not alteration of its angle but thinning of its walls, which cannot resist the devouring action of the cells of the vascular areolar tissue surrounding cancellous bones. The femur is in its upper part much dependent upon its cancellous portion, and, as the senile change occurs first in cancellous bone, there is a great difference between the effects of an unfavourably-applied force in fracturing this region at different times of life. The weakness of the bone structure does not, however, entail any loss of the osteophytic qualities of the cells thrown out from a fracture: hence union of fractures at the base of the neck of the femur is common, non-union being rather the exception. There is usually a large amount of new bone formed near the fracture, so that there is often a superabundance of new bone in fractures of the base in old people. Very often, indeed, the strength of the bony union is proportional to the amount of damage done. Fractures within the joint are most common where the bone is narrowest, that is, close to the head. Here union is liable to fail, though not from either want of bone-forming power in the patient or deficiency of blood supply, which is ample or repair in any part of the skeleton. The real causes of

¹ *Lancet*, November 17th, 1894.

non-union are two: (1) The fixation of the head in the acetabulum prevents the two fragments from overlapping, the amount of the bony surfaces which are approximated being diminished; (2) the new bone-forming cells are not retained in the neighbourhood of the fracture but escape into the joint. When the fragments are retained in apposition union is as sure as in other parts of the skeleton. Sir George Humphry illustrated this by exhibiting a drawing from a specimen taken from a patient whose age when the fracture occurred was 80, and who survived the injury a year. The fragments had perfectly united in front, there was no deficiency in the amount of bony material thrown out, and the patient was able to lift his leg from the bed in six weeks from the accident. The speaker did not think that the retinaculum of the neck had much to do with union. He pointed out that it is thicker and more closely adherent in front than elsewhere, and hence is more commonly torn through here than behind, where, though thinner, it is more loosely connected. He believed that the rapid absorption of bone noted by Sir William Stokes took place exclusively between the fracture and the trochanters, there being none between the fracture and the head. This was illustrated by a specimen which he showed. It was due to the rubbing of the trochanteric fragment against the structures of the inner side owing to movement and also to rapid absorption of the cancellous tissue from senile weakness and from the number of phagocytes in that tissue. He considered that the keynote of union was contact: if there was contact union resulted, with no contact no union. This led him to endorse Sir William Stokes's views as to the necessity of keeping the fragments in apposition and at rest.

III.—THOMAS BRYANT, F.R.C.S., Consulting Surgeon to Guy's Hospital.

MR. BRYANT assented fully to the opener's conclusions, but thought that the eleven varieties into which he classified the fractures were more valuable from a pathological than from a clinical aspect. There is not such a marked distinction as has been alleged between intra- and extracapsular fractures. It is clinically better to regard them from the point of view of impaction or non-impaction. All fractures anywhere are capable of repair, and of those under consideration there are only a few near the head in which good union is not obtained. R. W. Smith taught that all fractures of the neck were originally impacted, and only became unimpacted by a second force or by bad treatment. This dictum is often true, and the surgeon should have impaction in his mental eye as a guide to treatment. Mr. Bryant agreed that inversion depends upon an accident of position, and that impactions are all due to purely mechanical forces. In treatment he found that if the rules laid down by the opener were adhered to, union usually took place, so that by keeping the limb quiet with no friction, repair might be looked for. Of 42 consecutive cases, of which the average age was 70, all went out with good and useful limbs, and bed sores were unknown. How many of these cases were intra- and how many extracapsular, he had no idea; the union depended essentially on whether there was impaction or not. His treatment resembled that of the two preceding speakers, and he always abstained from turning the patient about too much, and from prolonged attempts to obtain crepitus. In special cases he acted in the same manner as Mr. Southam. Thus, in a lady of 30, who had an impacted fracture, with adduction and an everted foot as the result of a hansom cab accident, he loosened the impaction by rotating the condyle of the femur, and put on a double splint. In three weeks patient had recovered, the two limbs were of the same length, and an enormous quantity of callus had been thrown out. Impaction should never be loosened in an old subject, and the two opposite evils to avoid in any case were (1) simply leaving alone, and (2) reckless treatment.

IV.—E. H. BENNETT, M.D., M.Ch., F.R.C.S.I.,

Professor of Surgery, Trinity College, Dublin; Surgeon to Sir Patrick Dun's Hospital, Dublin.

THE first essential for the study of this, as of any group of fractures, is to classify them in some systematic manner. I arrange them in two divisions according as they are the product of force applied directly or indirectly to the bone. I

think that this arrangement is necessary in order that error may be avoided which is current with regard to the mechanism of some of the most common injuries, notably the extracapsular fractures of the neck of the thighbone.

Analysis based on 136 specimens. I record the number of specimens of each group under each head. I fear that some will object to the number of groups which I have made in each division, but I hold that the more complete we render our classification the more useful it will be found in practice.

Fractures of the Upper Third of the Thighbone caused by Direct Injury.

DIVISION A.			
1. Fractures of the trochanter major only	3 specimens
(a) Occurring in the adult bone...	0
(b) While the trochanter is an epiphysis...	3
2. Fracture through the trochanter...	3
3. Gunshot fractures involving the hip joint...	2
4. Transverse fractures of the shaft immediately beneath the trochanter...	2
	10

Fractures caused by Indirect Injury.

DIVISION B.			
1. Fractures of the head...	0 specimens
2. Separation of the superior epiphysis...	0
3. Ordinary intracapsular fracture...	46
4. Impacted intracapsular fracture...	7
5. Partial fracture of the neck...	0
6. Mixed intra- and extracapsular fractures of the neck (type intra)...	1
7. Extracapsular impacted fracture with fracture of one or both trochanters...	3
8. Extracapsular impacted fracture, type exceptional...	3
9. Non-impacted fracture of the neck secondary to comminuted fracture of the upper third of the shaft of the bone...	5
10. Fracture of the lesser trochanter only...	1
11. Fracture of the neck of the thighbone in ankylosis of the hip joint...	1
12. Oblique fracture beneath the trochanters...	0
	124
	10
	136

This surely is a long category, but as each and every lesion contained in it has been proved to exist by the pathological test, and where the known numbers are enough to establish it, each group has its distinct type.

I base my analysis on the collection of fractures of the upper third of the femur contained in the museum of Trinity College, Dublin.

I may be asked why in this classification I adopt groups of which the museum contains no specimens. I simply admit the defects of the museum, but I cannot adopt a classification which would omit groups the type of which have been fully established, and all of which I have myself seen except two. But these two—separation of the superior epiphysis and the partial fracture of the neck—are attested by absolute pathological proof.

The great size and importance of the Division B makes it desirable to briefly examine its details before noting those of Division A. The first group—fracture of the head of the femur—consists in the tearing off of the piece of bone which gives attachment to the ligamentum teres during dislocation of the hip joint.¹

Group 2 has been proved by post-mortem examination to be a possible injury, so that systematic writers can no longer doubt its existence.²

Group 3. Ordinary intracapsular fracture of the neck of the thighbone. The number of these in the collection is 46, which may well be considered in reference to the number of those that might be named the ordinary extracapsular fractures, 63. These relative numbers differ remarkably from those obtained by Malgaigne, which are 61 intracapsular and 42 extracapsular, and, if we take the total of all the groups included under the terms intra- and extracapsular, our numbers are 89 intra- against 71 extracapsular. I regret that of these 53 intracapsular fractures critical details are noted in but very few cases, and in no case is the cause of the accident sufficiently clearly stated to help us to an exact determination of its mechanism. I would like to note, however, that it has happened to me twice to break

¹ BARNETT, *Med. chir. Trans.*, vol. III.

² *Bulletin de la Société Anatomique*, 1867, p. 282.

the neck of the thighbone within the capsule in the attempt to produce the dorsal dislocation of hip by forced adduction of the thigh. I mention this fact, as I find that the most elaborate writer on injuries of the femur (Hennequin) stated that up to his date, 1877, he knew of no one who had been able to produce an intracapsular fracture of the neck of the

Fig. 1. Division B, Group 3. Ordinary intracapsular fracture of the neck of the thighbone

femur experimentally, while the extracapsular has been so produced by many. The subjects on which I produced these experimental fractures, quite unintentionally, were both old, probably between 60 and 70 years, so that the condition of atrophy of the bones which predisposes to the fracture in the

Fig. 2. Division B, Group 3. Absorption of the neck in old intracapsular fractures.

living was present in these bodies. Many of our specimens are fractures in which the death of the patient occurred very

shortly after the receipt of the injury, the fractured surfaces being sharp and unaffected by absorption. In all those in which the individuals lived long after the injury both the fragments exhibit absorption, so that the necks of the bones have almost clean gone; and this is true whether the union of the fragments is close and intimate or whether fibrous cords of considerable length connect them or they are quite disconnected; in some the fibrous union was so close and intimate that protracted healing alone established the fact that osseous union was absent. Many show polished surfaces, worn by the friction of the osseous fragments on each other, facts which go to prove that many individuals who suffer this injury preserve some amount of use of the limb, especially those who are provided with close fibrous union—facts which should lead us, if possible, to keep the fragments at rest in the earlier days and weeks of treatment rather than abandon them to the earliest possible passive movement.

Group 4 consists of 6 specimens which are all fractures strictly within the capsule, all impacted; in all the impac-

Fig. 4. Division B, Group 4. Impacted intracapsular fractures; left-hand figure also fracture of lesser trochanter, Group 10.

tion is the same, the lower fragment driven into the upper; in all bony union has occurred. Where a doubt might be

raised as to the nature of the union it has been tested by long boiling in water, a process which leaves the specimens rough and porous and friable. In one of these specimens the fracture is placed so close to the head of the bone that the margin of the head, as it were, overhangs the line of fracture. This form has been specially described as subperiosteal or greenstick fracture, but in its union no bone was deposited in the periosteum nor on the surface of the fragments, only the junction of the impacted osseous tissue holds the fragments together. It is clear that in these specimens we must attribute the union to the occurrence of impaction of the fragments after the occurrence of the fracture, in each the lower fragment has been rotated outwards as it was driven into the upper. The contest about the possibility of such union as these present, and the denials of the existence of such specimens as these may well end now, but every year we hear it renewed afresh in one form or another, even though as long ago as 1834 Sir Astley Cooper published his recantation of his old and loved doctrine. It is the maintenance of rest and apposition of fragments by the impaction that insures osseous union.

Group 5. I have placed this group in a prominent place merely to admit that a single genuine partial fracture of neck of the thighbone exists, the case recorded by Jackson in 1856 at the Boston Society of Medical Improvement, and preserved in the Warren Museum at Harvard. The references so often made to the early publications of Colles, of Adams, and even R. W. Smith on partial fracture of the neck of the thighbone, have been put aside by the later writings of the last two authors as being examples of intracapsular impacted fractures united by bone.

Group 6. Of this our series presents a single specimen in which the fracture is of the type of the intracapsular in its mode of impaction and osseous union, but a fragment was detached which pierced the capsule anteriorly.

Group 7. This group, the largest of all numerically, attests the constancy of the fact so much dwelt on by Professor Smith, but which so many writers question, "The extracapsular fracture is accompanied by fracture with dis-

Fig. 5, Division B, Group 5.—Impacted fracture with fracture of one or both trochanters.

placement of one or both trochanters." Among these 63 specimens there is no exception to this rule, and I think we may accept the doctrine that all these fractures are primarily impacted, and that the injuries in which the secondary fractures are separated and the head and neck are set free are the results of the extreme force of the impaction. I place these injuries among those resulting from indirect force, first because they are so in reality, the trochanteric region being broken by the intrusion of the neck into its tissue, not by its contact with the ground. The most common kind of accident that produces them is no doubt a fall on the great trochanter, but there is ample evidence that they may be caused by falls on the feet and on the knees, and by muscular action without any fall.

Group 8. Before discussing the most important questions

relating to fractures of the neck of the thighbone, their diagnosis and prognosis, I put forward this group of injuries, three in number; a few other examples have been published.

Fig. 6, Division B, Group 6.—Extra-capsular fracture, type exceptional; great trochanter unbroken.

Fig. 7, Division B, Group 7.—Intracapsular fracture, type exceptional; great trochanter unbroken.

I place them in a separate group chiefly to demonstrate their insignificance in numbers as compared with those of the last group. They are extracapsular fractures in which the great trochanter has not been broken; the mode of impaction in these is the reverse of the ordinary, the lower fragment penetrating the upper. The lesser trochanter is broken, and the base of the neck projects in front so as to cause a great increase in the bulk of the trochanteric region which in the united fracture is increased by the mass of callus deposited for the union of the fracture. In these fractures the injury closely resembles the ordinary fracture, but as the trochanter major escapes fracture we lose the evidence which this fracture offers in establishing the existence of fracture of the neck outside the capsule. I know of no other conditions in which the great trochanter escapes fracture but those presented by this group. I may now look to the bearing of the facts I have noted on the diagnosis of the extracapsular fractures. To the labours of Professor R. W. Smith and Maigne we owe the knowledge on which the diagnosis between intra- and extracapsular in their various forms rests; and, although it may not always be easy to establish it in the case of the recent fractures, still I hold that it can be made, and in our own interest as well as those of our patients it must be made. In the majority of intracapsular fractures osseous union will not occur, in the

extracapsular fractures it will, and at the end of a few weeks the most inexpert surgeon can readily distinguish the injuries. To many writers we owe the weak and damaging theory that the diagnosis while the fractures are recent cannot be made. To M. Gosselin, whose reputation as a great surgeon and teacher all will admit, we are most indebted for this mischievous doctrine. He says: "This rigorous diagnosis between the extracapsular fracture and an intracapsular is useless for both prognosis and treatment, consequently it is useless from any practical point of view." "For on these points no author up to this day (1873) has pretended to establish a rigorous diagnosis." And yet we see in Ireland and Paris this diagnosis established in 1847. But this teaching is rendered more pernicious by the statement made to support it from the view of treatment. "The fracture of the neck of the femur being, as you know, a malady of the aged, arthritis will develop in consequence of it, an incurable dry arthritis (that is chronic rheumatic arthritis), or if it does not pass into the condition of dry arthritis, it will leave during some months a painful stiffness of the joint." How many of our united extracapsular fractures are there which show these changes and how many do not? Five do, 23 are absolutely free from chronic rheumatic arthritis. The experience of every surgeon who has had to deal with these injuries is that he has seen a fair share of patients who have had extracapsular fractures walking freely and firmly, it may be with a halt, but without crutch or stick long after the injury. Surely it is well that the surgeon should be able to forecast this good result or on the other hand in dealing with intracapsular fractures save his own reputation by a clearly stated prognosis.

Group 9. This group of fractures of the neck of the thighbone differs from the preceding in the mechanism of the fracture of the neck, and in its cause. In this form there is no impaction of neck into the trochanteric region of the bone. I have already published the details of these fractures in a communication made to this Association at its meeting at Cork in 1890, showing that in certain spiral fractures of the upper third of the thighbone this segment of the bone is comminuted, and where the injury is complete the head and neck are set free. In the incomplete fracture of which I present three remarkable specimens, a fissure runs up and around the limits of the base of the neck, but the neck is not set free. These incomplete fractures of the neck enable one to read correctly the mechanism of the complete fracture: the wedge action

of the lower fragment in these cases was sufficient to crack the tissue of the upper; had the force been continued in its action the neck would have been completely detached. All these specimens and all that I know of, present the same striking feature, a long spike of bone extending down the greater part of the whole of the upper third of the shaft of the bone. In his paper on extracapsular fractures of the neck of the thighbone Professor Gordon describes this fracture as the fourth variety of impacted extracapsular fracture and recognises the fact that the fracture of the shaft attracting

Fig. 6. Division B, Group 9.—Non-impacted fracture of the neck of the thighbone secondary to fracture (comminuted) of the upper third of the shaft.

attention by the very definite character I have mentioned may cause the fracture of the neck to be overlooked. I have

Fig. 4. Division B, Group 9.—Non-impacted fracture of the neck of the thighbone secondary to fracture (comminuted) of the upper third of the shaft.

Fig. 10. Division B, Group 11.—Right hand figure, fracture of the neck of the thighbone in ankylosis of hip. Left hand figure, Division A, Group 3, gunshot fracture of the neck of the thighbone.

already in the paper referred to shown that this injury is produced by muscular action, not by falls on the hip.

Group 10. Fracture of the lesser trochanter (see Fig. 4); I know of no other specimen of this fracture. It is here associated with intracapsular fracture which is united by bone and we may reasonably conclude that the injuries, though independent of each other, were caused at the same time by forced abduction of the limb. I have seen this injury in the living, but I was not able to follow the case.

Group 11. I produce this specimen because of its rarity; that it was caused by injury done to a joint ankylosed by morbus coxae is proven by the fact that a piece of the cotyloid border broken off is included in the lower fragment. The kind of force is seen in the united fracture of the innominate which was associated with it.

Group 12. Our collection does not contain this injury, but the famous specimen represented in Sir Astley Cooper's book and the numerous specimens of the Royal College of Surgeons in Dublin attest its existence and importance. On this subject the writing of the late Mr. Butcher correcting the views of Sir Astley Cooper are well known.

FRACTURES OF DIVISION A. THE RESULT OF DIRECT INJURY.

Group 1. Fractures of the trochanter major only. The fractures of this process occurring in the adult are attested here by three specimens, and with one we have, as in a previous specimen, the history written on the innominate bone by a

Fig. 11. Division A, Group 1.—Fracture of the trochanter major

fracture of the same character. These specimens are sufficient to set aside the doubt expressed by a somewhat recent writer who uses the words "Fracture of the great trochanter without any fracture of the neck or shaft of the bone has been said to occur."

In the museum of Dr. Steevens's Hospital there was placed an example of the epiphyseal separation by the late Dr. Warren, of Dublin.

Group 2. Fracture through the trochanter. "Since the publication of Sir Astley Cooper's work on *Fractures* it has become the custom to describe this variety of fracture separately and a certain degree of vagueness or indefiniteness in the first description has been preserved in most of the subsequent ones." This doubt appears to exist because of the want of recorded specimens of the injury.

In this state of things I need not make apology for presenting three very perfect specimens, two of them united fractures, one of recent injury which was produced in a man who was struck down and killed by a railway truck in the making of one of our earliest railways. The statement made that in this injury "there is shortening, sometimes very considerable, great eversion of the limb," is in no way

supported by these specimens; and in the living in whom I have been able to recognise the injury the diagnosis was arrived at rather by way of exclusion than by the existence of such marked signs as I have quoted. It was only after a long interval that the diagnosis was made in Sir Astley Cooper's case; the accident occurred on July 20th, and on August 14th the diagnosis was first made by the discovery of crepitus and the prolonged inability to use the limb without

Fig. 12. Division A, Group 2.—Fracture through the trochanter major.

any of the signs of the other forms of fracture which occur in this region. If we want to avoid the unpleasant question put by the patient to Sir Astley Cooper on that day, "Why, you do not mean to find a fracture now?" we must have a clearer idea of the injury than is conveyed in the sentences I have quoted.

Group 3. This group it is obvious must be maintained (see Fig. 10). Our collection contains but two such injuries; in one a bullet is lodged in the neck of the bone, and the patient died under the expectant mode of treatment.

Of the second specimen I have already published the details with photographs. I place it here merely because of

Fig. 13. Division A, Group 4.—Transverse fracture of the shaft of the femur immediately beneath the trochanter.

Its rarity, for that the expectant treatment was successful there is in this case no doubt. The bone presents united

¹ *Transactions of the Royal Society of Medicine*, vol. viii, p. 104.

³ *Transactions of the Royal Society of Medicine*, vol. viii, p. 104.

fractures of the upper end, which radiate from a tunnel in the neck reaching downwards as far as the lower third of the bone; ankylosis of the hip followed the lesion, and the condition of the bone, the atrophy of the cancelli of the head where they ceased to transmit pressure, and their hypertrophy under active use, all prove that the patient recovered from his wound and walked on the limb. All doubt of the diagnosis of the lesion in this graveyard specimen is removed by the finding in the tunnel ample traces of carbonate of lead.

Group 4. Transverse fractures, fractures of the shaft immediately beneath the trochanter. I submit two most perfect specimens, one united with the barest sign of angular deformity outwards. In the second, the deformity is at a maximum, while the lower fragment is so remarkably inverted that previous to the dissection of the limb the features of dorsal dislocation were simulated.

V.—J. GREIG SMITH, M.B., O.M., F.R.C.S.E.,

Surgeon to the Bristol Royal Infirmary; Professor of Surgery at University College, Bristol.

AFTER referring to the large knowledge and wealth of illustration of this subject exhibited by the Dublin School, Mr. Greig Smith proceeded to supplement certain points on which previous speakers had touched less fully. He first appealed for a simpler classification, since the pathological one ran the risk of elevating a rare variety into a separate species. A causal classification gives (1) indirect violence applied directly vertically, and resulting in fracture of the neck near the head; and (2) direct violence applied transversely to the great trochanter, which produces fracture near the base. In the first case there is never any injury to the joint unless the patient falls directly on it. The obliquity of the fracture in the neck is of the greatest importance as regards both union and deformity. We walk normally on the posterior half of the femoral neck only, and hence, in falling, chip off more of this part than of the anterior, the line of the fracture running from before, back, and out. From this obliquity eversion can be deduced by a simple resolution of forces. Inversion is a mere accident of position. Non-union of fractures high up in the neck is due to the causes stated by Sir George Humphry, and also to the fact that no nidus for the development of new bone is present in this region. At this spot there is no cellular tissue to undergo the primary calcifying cellulitis, but only blood clot, and perhaps bits of ligaments; whereas at the base cellular tissue abounds. In treatment, Mr. Bryant's rules as to the importance of the question of impaction, and the non-importance of other variations should be adhered to. In young patients impaction should be reduced, in old not.

VI.—A. W. MAYO ROBSON, F.R.C.S.

Senior Surgeon, Leeds General Infirmary; Professor of Surgery, Yorkshire College, Leeds.

SIR WILLIAM STOKES'S classification is based only on the post-mortem room, and has but little real clinical interest. These fractures should be classified into impacted and unimpacted, and in old people it is not even necessary to take much trouble to ascertain the fact of impaction. In treatment the main object is apposition; the parts should be disturbed and manipulated as little as possible, and constitutional disturbance looked out for. The treatment of young and old patients is essentially different. The latter are put to bed, and then, if nothing untoward happens, treated as in early life with a long splint and a weight to keep it steady. If recumbency is badly borne, a Thomas's hip-splint is applied, securely fixed with starch or plaster, and the patient allowed to get about. Mr. Southam's case belongs to a different class, and his treatment had, in Mr. Robson's experience, often been adopted before. It is not right to allow a young patient to go about for the rest of his life lame, and with an inverted and shortened limb when this can be relieved surgically. Here the treatment is to relieve the impaction and secure a good position.

VII.—THOMAS SINCLAIR, M.D., F.R.C.S.,

Assistant-Surgeon, Belfast Royal Hospital; Professor of Surgery, Queen's College, Belfast.

DR. SINCLAIR drew attention to the frequency of osseous

union in intracapsular fracture of the femoral neck, which is greater than commonly supposed. It was therefore desirable to strive to secure osseous union, which occurred in fractures close to the articular head, as illustrated by three specimens, as well as in those fractures nearer the middle of the neck, as illustrated by nine specimens from the collection of the late Professor Gordon, of Belfast. But, having regard to the physical and mental deterioration caused in aged persons by long recumbency, it was well to distinguish those cases of intracapsular fracture that were likely to unite by bone, namely, those produced by force acting from before backwards, including extreme external rotation, in which the periosteum was little injured, from those due to a force acting from above downwards, as when the weight of the body bore upon the neck during abduction in the production of the common form of intracapsular fracture. In the latter case the body, after breaking the neck, being still in projectile force, followed on by the influence of gravity to lacerate the periosteum. As this laceration, by permitting free movements and displacement at the seat of fracture, was the chief cause of non-union, it would be wiser not to risk too much in the way of long recumbency in an attempt to secure osseous union. Under these circumstances, after a couple of weeks, the attempt might be abandoned, or better, a mode of fixation adopted from the outset which did not involve recumbency. The cause of disappearance of the neck was mainly mutual attrition between the fragments, and in those instances in which absorption followed simple contusion of the hip the opinion was expressed that these were probably intracapsular fractures with so little displacement that the ordinary signs of fracture were not demonstrable. With regard to extracapsular fractures, the advantage of an elaborate classification, like that suggested by Sir Wm. Stokes, lay in that we were able to understand how each one of the classical signs of this accident might vary to its opposite—shortening to lengthening, eversion to inversion, and so on—and thus learn that no single sign could be depended upon as pathognomonic. In the treatment of extracapsular fractures there could be no difference of opinion that in non-impacted forms splints, with or without extension, were demanded; but in the impacted cases in old people, in whom it would not be wise to disturb deliberately the impaction as it might in young subjects, the view was expressed that there was still room for difference of opinion as to the necessity of apparatus of any kind, seeing that if the surgeon took care not to disturb the impaction in making his diagnosis, the patient could be trusted not to do so by his or her bodily movements during the treatment, except perhaps in those few cases in which traumatic delirium or other complication arose.

VIII.—SIR WILLIAM HINGSTON, M.D.,

Surgeon to the Hôtel-Dieu, Montreal.

SIR WILLIAM HINGSTON had come to the meeting not to impart information, but to carry back crumbs of knowledge to Canada. He was pleased and somewhat surprised to find the opinion here that union in these fractures was the rule and shortening the exception, results which were certainly not in accordance with experience on the other side of the Atlantic, as exemplified in the *pronunciamento* of the Chicago Conference twelve years ago. In Canada the results were so bad and actions-at-law so frequent, that it was sometimes difficult to get a doctor to attend a case of fracture of the neck of the femur.

IX.—F. J. GANT, F.R.C.S.,

Consulting Surgeon, Royal Free Hospital.

MR. GANT had never seen a case of fracture of the cervical neck which did not result in shortening. The diagnosis of these cases did not appear to be understood except by surgical specialists, and cases of fracture were often treated as rheumatism.

X.—S. H. WEEKS, M.D.,

Portland, Maine, U.S.A.

THE diagnosis in the United States was based on the following points: The age and history, the position and helplessness of the limb, and especially the pain, which was increased on the slightest movement. Mr. Bryant's line was

also found a most satisfactory aid. Intracapsular fractures arose in aged subjects from slight violence, while the word "extracapsular" was a misnomer, fractures through the base being both within and without the joint. The treatment was to correct eversion by Bryant's splint, or better still by light extension with Liston's long splint and a footpiece or sand bag.

XI.—C. B. KEETLEY, F.R.C.S.,
Senior Surgeon, West London Hospital.

THE following case illustrates the treatment of fractures of the upper part of the neck: A girl, aged 18, one year after fracture of the neck was still crippled and unable to stand, and there was a mass of bone below the anterior inferior iliac spine. Most of the head was out of the acetabulum, and had ankylosed with the ilium, and the stump of the neck had become mushroom-like. Mr. Keetley removed both, and the patient was practically cured and able to return to her laundry work. With regard to Sir William Hingston's pleasant sarcasm, Mr. Keetley had found that shortening was very rare in London, as, except in fracture of the actual neck, he had only been able to collect two or three cases in the last two years. He stated by the use of two L-shaped steel pins introduced into the fragments some little way from the fracture, and fastened outside the skin by wire, shortening was entirely obviated. The splint treatment had, however, also to be adopted at the same time.

XII.—F. A. SOUTHAM, M.B., F.R.C.S.,
Surgeon, Manchester Royal Infirmary.

MR. SOUTHAM wished to direct attention to the unsatisfactory result which followed the method of treatment usually adopted in impacted extracapsular fracture of the neck of the femur. This consisted in simply keeping the limb at rest, without making any attempt to correct the characteristic deformity, the shortening and eversion of the leg, always present in a greater or less degree. It consequently remained permanently deformed, and the patient was therefore seriously crippled for the rest of life. With the view of preventing this result in a case of this injury which was under his care in the Manchester Royal Infirmary last year, the impaction was at once broken down under anaesthesia, the eversion was overcome, and the limb was restored by traction to its normal length. The fracture was then treated in the ordinary way, extension being kept up by means of a weight, and a Lister's splint being applied to the outside of the limb. At the end of a month the limb was put up in a plaster-of-paris bandage, and when this was removed, in the course of about six weeks, it was found that perfect union had taken place with the limb in the corrected position, without any shortening or eversion, the movements of the joint being quite free. Two similar cases had recently been treated in the same way with equally successful results. He was aware that this method of treatment, which he wished to recommend, was somewhat unorthodox, and quite at variance with the usual teaching of surgeons, there being a traditional dread of union not taking place if the fragments were separated by breaking down the impaction. Inasmuch as this fracture was frequently met with in middle-aged persons in whom the neck of the bone had not become the seat of the atrophic changes occurring at a later period of life, there was little fear of this result, and he therefore advocated reduction of the deformity by breaking down the impaction in all cases when the patient was of a good constitution and not advanced in years.

SIR WILLIAM STOKES'S REPLY.

HE was pleased at the importance and interest of the discussion elicited by his paper. He agreed with Sir George Humphry as to the blood supply as long as the cervical ligament was uninjured, but considered injury to the latter the main cause of non-union in these fractures. He was sorry that some of the speakers had objected to his classification as being founded on the museum or the post-mortem room, but he wished to point out that most classifications which were of use in clinical surgery were based on post-mortem investigations, and that his own formed an efficient guide to prognosis. He was not aware, from any published writings,

that the Leeds school had anticipated Mr. Southam in laying down the principle of disimpaction. He disagreed with Professor Sinclair's view that the presence of osseous union in some cases obviated the necessity for mechanical interference. He reminded Sir William Hingston that in the practice of one American surgeon at least—Professor Senn, of Chicago—good union with a minimum degree of shortening was the rule. He considered that Mr. Keetley's clamp—which resembled an apparatus designed by the late Professor Wood, of New York, for use after resection of the knee—was much too flexible for use in fractures of the cervix femoris.

ON MOVABLE KIDNEY.

By KENDAL FRANKS, M.D., F.R.C.S.I.,
Senior Surgeon to the Adelaide Hospital, Dublin; Surgeon in Ordinary to his Excellency the Lord Lieutenant.

SOME years ago there were many medical men who did not believe in the existence of a mobile kidney. This was partly due to the fact that abdominal operations were rare, and therefore the diagnosis of a movable kidney had little chance of being verified; hence the unbelievers in this condition, in the presence of a mobile tumour within the abdomen, were prepared for any diagnosis except that of a kidney which had been dislocated. This want of belief was also partly due to the infrequency with which this condition is found in the dissecting or post-mortem room. This infrequency is the result, I believe, to two causes. Mobility of the kidney is rarely looked for, and with a subject lying in the dorsal position the kidney naturally sinks back into its normal place, and may thus easily escape detection. Moreover, as pointed out by Newman, the fatty envelope becomes solidified after death, and would tend to fix a kidney which during life had been freely movable.

There are few to-day who will venture to deny that a kidney may be mobile. The present tendency of the medical mind is to assert that it is not a condition of frequent occurrence, that it is not of serious import, that for the most part it is an invention of the surgeon, more given to enterprise than to exactness of diagnosis.

With these views I cannot agree. Mobility of the kidney is of far more frequent occurrence than is generally admitted. Any man who will take the trouble to look out for these cases will be surprised to find how very frequently he will meet with them. There is of course every degree of mobility of the kidney to be found, but all are not pathological. When I speak now of a movable kidney, I draw a distinct line between the varieties or degrees. Suppose we get a patient lying in the dorsal position. Standing on the right side I pass the four fingers of my left hand underneath the hollow of the loin below the twelfth rib. The thumb in front encircles the abdomen just below the costal arch, but without exercising any pressure. I then direct the patient to draw a full breath. Immediately before expiration begins I press with my thumb upwards beneath the costal arch, and let it sink in as deeply as possible, following the liver as it recedes during expiration whilst the fingers behind press the loin forwards. If now with my right hand I can feel the kidney lying entirely below the grasp of my left hand, I call that a right kidney pathologically movable. If the right hand presses on the tumour so felt, whilst the left hand relaxes its grasp gradually, the tumour can be felt to slip between the fingers of the left hand and to disappear from our ken—upwards into the position normally occupied by the kidney. This sensation is, I believe, pathognomonic of a movable kidney. A kidney which can be felt to descend so that its lower half may be felt, but which moves back on expiration, is a kidney physiologically movable.

Considerable diversity of opinion exists as to the cause or causes of movable kidney. The theoretical nature of these opinions emphasises the difficulties which surround the question. Thus Cravinhier attributes renal mobility to the pressure exerted upon the liver by slugs; Lauroaux to the physiological and pathological relation between the kidneys and the generative organs; Gottmann to the congestion of the kidneys which occurs during menstruation. These organs then tumefy, become heavier and have a tendency to leave their normal position and to descend little by little into the abdomen. Newman considers that the kidney is

originally forced out of its place by the force of the anterior and posterior abdominal muscles during a strain, such as during delivery, or in lifting heavy weights. "The resultant of these forces will act in a manner similar to what takes place when one presses a bean between the finger and thumb—that is to say, the kidney will be pressed downwards."

Now before we can adequately discuss this vexed question, we should consider the means which Nature has provided for keeping these organs in their normal position. We find the kidney surrounded on all sides by a fatty capsule and by connective tissue. I do not think we ought to lay too much stress upon the fatty capsule, for though after death we may find this pretty firm and affording apparently some considerable amount of support to the kidney, during life it is in a very different condition. The fat then partakes more of a fluid than of a solid character and would unquestionably allow of a certain amount of motion. Yet that it does exert some influence is shown, I think, by the greater frequency of movable kidney amongst the lean and emaciated than among the well nourished. Still I have met with freely movable kidneys among women who were anything but insufficiently supplied with adipose tissue, and I believe that too much importance has been attached to the absence of fat as a cause determining mobility.

Of more importance, however, is the connective tissue which binds the kidney to the loin behind and to the various abdominal viscera above, below, and in front. In the latter position it is assisted to no inconsiderable degree by the peritoneum reflected over its anterior surface. In probably a majority of cases these connective tissue adhesions and the disposition of the peritoneum are sufficient to maintain for a time the kidney in its place, even where causes operate which would dislocate an organ with less firm connections. These connections are not in themselves sufficient to withstand alone the weight of the kidney, but they are important to bear in mind from another point of view, for, as I hope presently to show, though they may not keep a kidney in its place when once it has become dislocated they are mainly responsible for the symptoms which accompany a movable kidney and which may make life unendurable.

I now come to what I believe is the great factor for maintaining the kidney in its proper position, and I am very much indebted in regard to this matter to the researches of my friend Professor Cunningham and to his kindness in placing his material at my disposal.

The researches of Professor His and of Professor Cunningham have clearly shown that the form of the kidney itself and the influences exerted upon it during life, or rather in the unopened body, vary very materially from what is usually observed in the dissecting room or on the *post-mortem* table. The method employed lately by Professor Cunningham with the view of obtaining an accurate knowledge of the true form of the solid viscera of the abdomen, is shortly this: Having selected two well-formed subjects, he proceeded to harden them by the injection method. He employed Müller's fluid, followed by graduated spirit injections. In the case of one of the subjects, the injections were repeated almost daily for a period of two weeks, whilst in the other the hardening process was continued for fully six weeks. By this method all the internal organs were hardened *in situ*, before any disturbing influence had been introduced by opening the abdomen.

As regards the kidney, and with the kidney we are now alone concerned, the results have been most remarkable. The kidneys present many slight changes in form, according to the amount and the kind of pressure which is exerted upon them by contiguous viscera; and these changes undoubtedly are continually taking place in the same individual. We need not interest ourselves at present over these slight variations, but we should fix our attention on the more constant conditions of forms which the illustrations clearly show.

Professor Cunningham thus describes them: "In every case and on both sides there is on the anterior surface a point of maximum convexity, a place where the kidney substance is raised in the form of a marked prominence or bulging, which may slowly rise from all sides to a blunt summit, as is usually the case in the left kidney, or which may extend across the anterior surface in the form of a

rounded ridge, as happens more commonly in the case of the right kidney. Above and below this eminence the anterior surface falls away towards each extremity in the form of an inclined or sloping plane of greater or less obliquity. (See Fig. 1.) These impressed districts indicate

Fig. 1.—Outer convex borders of the right and left kidneys, showing the wedge-shaped outline of the kidneys when viewed from this aspect; also the central prominence and the two inclined surfaces on the anterior aspect of each. pressure exercised on the anterior surface of the kidney in two directions, and the intervening eminence is the result of this counter-pressure. Upon the upper inclined plane of the anterior surface of the left kidney are placed the suprarenal capsule, the stomach, and the spleen. These exercise a downward and a backward pressure. Upon the inferior inclined surface of the left kidney the counter-pressure is produced by the intestinal canal, which presses as a rule upwards and backwards (see Figs. 2 and 4). On the right side the upper

inclined surface is occupied by the liver, whilst in contact with the lower in l. n. d. r. s. is the colon. In many cases the

colic or inferior sloping surface presents a high degree of obliquity." (See Fig. 3.)

We see, then, that on the right side we have two forces acting on the kidney: one, acting from above, presses the kidney downwards and backwards; the other, acting from below, presses the organ upwards and backwards. The resultant of these forces will be a force acting almost directly backwards, wedging, as it were, the kidney into the position it usually occupies. Now, the pressure from above is practically constant. It varies somewhat with the position of the body, and also during respiration. But these variations do not really affect the question, for the liver, kidney, and colon move together under the circumstances, and the relative position of the forces is practically unaffected.

The pressure from below varies to a much greater degree with the varying conditions of the intestine itself. It diminishes where the bowels are empty; it increases with abundant distention. Still the general direction of the pressure, upwards and backwards, on the inferior inclined plane of the kidney is maintained. The effect of these normal variations of the two forces is shown in the illustrations. In one kidney we find the transverse ridge on the anterior surface is near the middle of the organ, in another we find the ridge is below the junction of the middle and lower third. Slight alterations in shape appear to be the main results of these frequent variations between the upper and lower compressing forces.

Now if the balance between these forces be lost, so that their resultant acts in a more or less downward direction, it is easy to conceive how the kidney itself, aided by this downward force and by its own weight, would gradually sink, making a way for itself behind the peritoneum which lines the back below it.

There are several ways in which this balance of pressure may be destroyed. An obvious example is after parturition. We know that normally the pressure within the abdomen is positive, but immediately, and for some days at any rate, after parturition, the pressure becomes negative. If during this period the patient assume the erect posture, the pressure from above acts downwards and backwards unopposed, and unless the cellular connections round the kidney are sufficiently and unusually firm, the kidney must gradually yield to the combined forces, and slip from its place. Each act of parturition, with shortened respites in bed, will increase this tendency, and it is difficult to understand how the kidney, having once slipped from the control of the colon, could ever again regain accurately its relative position, so as to be wedged between it and the liver, as we have seen it normally is. Probably a movable kidney, when it slips into place in the recumbent position, lies behind the colon and

below the liver, its anterior surface being flattened, so that the wedging forces can no longer act. Another method by which the balance of power may be destroyed is by traumatism. If by means of a violent shock, such as a fall from a height on to the feet, or by means of extreme pressure, as the passage of a cart wheel across the body, the kidney be forced downwards out of its bed, the equilibrium of forces is disturbed, not to be again restored. I have elsewhere recorded several instances of such traumatically dislocated kidneys.

Besides the ridge and planes on the anterior surface there are other markings on the kidney which may be shortly alluded to. The duodenum almost invariably rests upon the anterior surface of the kidney, and it gives rise to a very evident duodenal impression. The outer convex border of the kidney of both sides presents a marked thickening opposite the eminence on the anterior surface. In the neighbourhood of this thickening a faint groove passing upwards indicates the place where the border of the kidney is "clasped" by the last rib. (See Fig. 1.) This is worthy of notice, as it supports those who advocate fixing a movable kidney to the last rib. The posterior surface of the kidney exhibits three well-marked areas, which correspond respectively to the psoas internally, to the quadratus lumborum externally, and to the diaphragm above. Between the areas marked by the psoas and the quadratus lumborum muscles dimples corresponding to the transverse processes of the lumbar vertebrae may sometimes be observed in spare subjects. (See Fig. 5.)

Fig. 5.—Posterior surface of the left kidney. (Note the vertical ridge which separates the surface of the kidney into an internal and an external district.) d. Surface in contact with the duodenum. p. Impression for the psoas. q. Impression for the quadratus lumborum. v. v. v. Dimples corresponding to the tips of the transverse processes of the first, second, and third lumbar vertebrae.

I have hitherto taken the right kidney for my text because dislocation and mobility are much more frequent on the right than on the left side. The proportion is about 11 to 1, and it is not uncommonly bilateral. It will be understood that the arguments which have been adduced regarding the right kidney apply to the left also, taking into consideration the altered relations on the left side.

The symptoms produced by a movable kidney are many and varied. They may practically be said, and some accident alone reveals the presence of a movable tumour within the abdomen. Or, on the other hand, to quote the words of Keen, "the discomforts are very great, and the pain may be so excessively severe and prolonged as to interfere with all

occupation, and practically to make life almost unendurable. "The disorder may pass beyond the realm of bearable evils into serious and actual danger to life itself." Between these extremes we find every variety of discomfort and every degree of pain.

In attempting to explain the connection between these symptoms and the mobility of the renal organs again we find that the imagination has been fertile in the production of theories. The nervous system, of course, is largely called upon, and the well known gastric crises, in which severe abdominal pain and distension of the stomach are not infrequently followed by vomiting, are attributed to the reflex disturbance caused by dragging upon the renal vessels and nerves. The causation of these gastric crises was discussed at some length at the Société Médicale des Hôpitaux in Paris in 1892, and the explanation then supported was that offered by Bartels in 1884—namely, that when the right kidney was displaced and came in contact with the second portion of the duodenum, the compression might be sufficiently strong to cause dilatation of the stomach.

Now, I think an examination of the kidney relations will show that such a compression of the duodenum is impossible, unless we were to suppose that the kidney could leave its bed in the forward direction, and could fall over across the duodenum towards the other side of the body.

The symptoms of movable kidney are, I believe, to be explained in a much more simple way. For convenience they may be divided into three groups:

1. Those symptoms which are common to both right and left movable kidney.
2. Those symptoms which belong exclusively to mobility of the right kidney.
3. Those symptoms which may be found when the left kidney is mobile.

In the first group I include a dragging pain in the abdomen, and a sense of weight in one or the other side, neuralgic pains in the loin or shooting down the thigh, fatigue on slight exertion, and general debility, which makes any effort a weariness to the flesh. Many of these symptoms may, with some justice perhaps be attributed to the "dragging upon the renal vessels and nerves."

The second group comprises those symptoms which we recognise in their severer form under the term "the gastric crises." In the milder form the chief complaint is indigestion, flatulence and sometimes vomiting. The following points can generally be elicited. The indigestion does not depend on the kind of food taken. One patient told me she had made the round of all sorts of food, and that nothing made any difference. Pain generally comes on about one or two hours after food, and large quantities of gas are frequently belched up. The usual remedies for indigestion and flatulence are of little if any use. I have frequently been told that the only relief to be obtained was by lying down, and one lady informed me that she always found ease by kneading her right side. Such a train of symptoms should always make us suspect a movable kidney on the right side. Now these symptoms can be explained on purely mechanical grounds. In October, 1892, I opened the abdomen of a woman who had what was diagnosed to be a most abnormally movable kidney. The opening was made in the right linea semilunaris, and the kidney was found lying in the right iliac fossa. The cause of all the symptoms was at once obvious. The kidney was attached by strong bands to the descending portion of the duodenum, and when the kidney fell towards the iliac fossa, it so dragged upon the duodenum as to kink it, and it was obvious that in that state nothing could pass out of the stomach. The stomach was in a state of dilatation. The symptoms from which she suffered and which she herself described as agonising disappeared when the kidney was fixed into its proper position.

Now, if we examine the normal relation of the descending portion of the duodenum to the kidney, we find that it generally lies on the inner portion of the anterior surface; sometimes, as in the engraving (see Fig. 6) it covers more than half the surface of the kidney, but this is an unusual amount. Occasionally though very rarely, it does not touch the kidney at all, but lies on the renal vessels and the commencement of the ureter. The kidney and the vertical portion of the duodenum are bound together by connective tissue,

which may sometimes be extremely lax and weak, sometimes may have an appreciable degree of strength. Both organs are retroperitoneal. Now what I believe occurs is this.

Fig. 6.—Reproduced by permission from the *Journal of Anatomy and Physiology*, July, 1894. a, right suprarenal capsule; b, hepatic artery; c, portal vein; d, bile duct; e, superior mesenteric vessel; f, right kidney; g, duodenum; h, diaphragm; i, spleen; j, left suprarenal capsule; k, left kidney; l, aortic artery; m, pancreas; n, tenth rib; o, eleventh rib; p, twelfth rib; q, left kidney.

In many cases when the kidney slips, its attachment to the duodenum may be so slight and lax, or the surface in contact with the duodenum may be so small, that the kidney disengages itself from the duodenum, and may become freely movable in the abdomen, without in any way interfering with the gut. Under such circumstances we have, what is a not uncommon experience, a freely movable kidney presenting no symptoms—a condition very difficult to explain on the usual theories laid down.

If, on the contrary, the surface of contact between the kidney and duodenum be extensive, when the kidney loses its usual support, and begins to descend behind the peritoneum, it gradually drags the duodenum with it, and as in the instance in which I had the good fortune to observe what occurred, the duodenum kinks, and a temporary condition is induced very similar in its symptoms to what we find in stricture of the pyloric end of the stomach. This view is further strengthened by the fact that marked dilatation of the stomach is found in some of these cases.

These gastric symptoms, I believe, are not found when the left kidney is alone at fault. Dislocation of the kidney is very much more uncommon on the left than on the right side. It is difficult, therefore, to speak of the symptoms produced by a mobile kidney on the left side with as much confidence as we can of the symptoms produced on the right side; but this I can affirm: I have never seen the gastric crises, nor anything like them in any case of left movable kidney that has come under my notice. Such cases have generally been quite symptomless, with the exception, of course, of the symptoms in Group 1, which, however, may be so slight as not to call for treatment.

If we examine the relations on the left side, at first sight there does not appear to be any reason why the left kidney, slipping out of its place, should interfere with any organ in its neighbourhood. But I have had reason to change my view regarding this, owing to a circumstance which has still further convinced me that the causation of the symptoms produced by right movable kidney is as I have stated above. In March, 1894, I saw a lady in consultation who suffered from extreme debility, inability to walk, caused by a feeling of weight in the abdomen, complete exhaustion after any attempt at exertion, distension of the abdomen and aggravated constipation. She had been ailing since the beginning of 1892. Castor oil and turpentine enemata gave her no relief, and large doses of cascara, or of castor oil very frequently were unavailing. On examination I found she had both right and left kidney movable, the left most marked. An abdominal belt and massage improved her considerably, especially as regards the constipation; but as

her progress was not altogether satisfactory. I performed nephrorrhaphy on the left side on April 10th last. At the operation I found a very interesting state of affairs. The kidney was firmly fixed to the splenic flexure of the colon and as it fell downwards it carried the colon with it, so that it became kinked forming a V bend. That this was the cause of the intractable constipation was proved by the sequel. The wound in the loin healed without suppuration, but I kept the patient lying in bed for six weeks in order to allow the adhesion the kidney had contracted to the loin to become firm. When she began to go about she rapidly regained strength, and when I last saw her towards the end of June the constipation had entirely disappeared, and for three weeks she had taken no aperient of any sort. She was able to go about as much as she wished. This case, if unusual, is most instructive, for it indicates that if symptoms other than those comprised in Group I arise, the symptoms will be due to traction on neighbouring organs, and the one most likely to suffer is the colon, so that constipation may be included in Group 3. Further experience must show what other symptoms may be added hereafter.

In thus grouping the symptoms, and bearing in mind their significance when taken together, I think that cases of movable kidney ought to be diagnosed with greater facility and accuracy than is done at the present day. Such symptoms tell a tale which a very rapid manipulation of the abdomen will generally verify, though sometimes it may refute it.

I do not propose on the present occasion to enter at any length on the question of treatment; surgeons are to a great extent agreed as to the cases which require palliative and those which require radical treatment. Nephrorrhaphy is, comparatively speaking, a safe operation. Our object in resorting to it is not merely to suture the kidney into the loin, but to the best of our ability to keep it there. A great deal has been written and said on the method of suture, and the best materials to employ. Many advise that the kidney should be fixed to the edges of the wound, some that it should be fastened to the last rib. I think it matters little which method we adopt. As a matter of fact I have for a long time been in the habit of suturing it to the twelfth rib. When we see in the kidneys hardened *in situ*, that the upper margin is marked by a groove where the kidney is clasped by the twelfth rib, this gives us a clear indication as to the proper position the sutured kidney should occupy. The material employed for suture is also a matter of no moment. I always use catgut now because it becomes absorbed. There are two considerations of the first importance: the first is to have plenty of material thrown out to glue the kidney into its place, and, secondly to allow no strain upon this material until it has had time to become organised and sufficiently strong to withstand any reasonable strain put upon it. The best way of ensuring the first of these desiderata is to employ the method, first suggested, I believe, by Mr. Jordan Lloyd, namely, to divide the capsule of the kidney at the place where it is proposed to pass the suture, to partially strip it off, and to suture the capsule and the renal parenchyma to the wound, or to the last rib, if preferred.

To secure the second object we should keep the patient lying in bed for at least six weeks, no matter whether the wound has healed by first intention or not. A patient who will submit to an operation in order to be relieved from the inconveniences or perhaps agonies of a movable kidney, will generally consent willingly to a little extra confinement in order to insure that the operation shall not have been in vain.

MR. BLAND SUTTON expressed his great interest in the demonstration, particularly in the question of the normal retention of the kidney in its place. He had seen jaundice simply from dragging down of the viscera by a movable right kidney. He considered that a mobile kidney, sliding up and down in a groove behind the peritoneum was quite common, especially on the right side, and formed a real source of suffering, though often diagnosed by physicians as hysteria. Dr. Franks had conclusively shown that mobile kidneys are a source of real and serious trouble.

ON RHINOPLASTY IN INDIA.

By Brigade-Surgeon-Lieutenant-Colonel D. F. KEGAN, M.D., F.R.C.S.

BRIGADE-SURGEON LIEUTENANT COLONEL D. F. KEGAN gave a lantern demonstration on rhinoplasty in India, notes of which are as follows:

In Europe, in the great majority of cases, rhinoplasty is performed in order to repair the ravages and disfigurement caused by lupus or tertiary syphilis, and it is but seldom that plastic surgery is called upon to make good the damage done to a nose by accident or mutilation. In Eastern countries and more especially in India, rhinoplasty is usually performed to repair the ghastly disfigurement caused by mutilation, and our patients are, as a rule, young, healthy, and robust. All those who have had much experience of rhinoplasty are, I think, agreed that the principal difficulties in obtaining good results centre in the formation of the columna and in obviating the continued tendency to contraction in the nostrils of the newly formed nose—a tendency which continues for several months after operation. The details of the operation, which I have devised as the result of many years' experience of rhinoplasty, are fully described in Mr. Treves's very comprehensive treatise of surgical operations; and therefore, on the present occasion when time presses, I shall merely state that the special feature of the operation consists in utilising the skin and tissues covering the nasal bones with the view of preventing the contraction in the nostrils of the newly formed nose. The skin and tissues clothing the nasal bones are dissected from off their bed, and the dissection is made from above downwards. The skin and tissues thus raised from their bed are reflected downwards, and therefore the skin of this nasal flap looks backwards and its raw surface forwards. A flap is now raised from the forehead, and is brought down and placed on the nasal bones and on the raw surface of the flap taken from off the nasal bones. It therefore follows that the inside of the newly formed nose is lined with skin, and this lining prevents any subsequent contraction.

The exact size and shape of the flap taken from the forehead is shown on the back of each photograph which I have the honour of submitting for inspection, and it will be seen that the shape and size vary in each case, although it will be remarked that all the forehead flaps present more or less a family likeness. The shape or outline of this forehead flap differs considerably from what one generally sees depicted in most English surgical textbooks. The sides or lateral margins of the forehead flap are most accurately attached by means of fine horsehair sutures to the bed prepared for them. The flap raised from the forehead includes all the structures down to the pericranium, but does not include the latter. I usually allow a fortnight to elapse before dividing the root or pedicle of the new nose, and in doing so I cut a wedge-shaped slice out of the root, so that the new nose may not be parrot-shaped.

A HITHERTO UNDESCRIBED LOCALITY IN THE MALE URINARY BLADDER WHERE A STONE MAY ELUDE CONTACT WITH ANY URETHRAL INSTRUMENT.

By G. BUCKSTON BROWNE, M.R.C.S.

In most cases of vesical suffering the presence or absence of a stone is a question of great importance. The history of surgery is full of cases of mistake in the diagnosis of vesical calculi. A stone is found which has been searched for by others and not found; a bladder has been opened and a stone found which had never been felt when searched for by instruments introduced through the urethra, whilst, on the other hand, a stone found by an ordinary sounding has not been detected when the bladder has been opened by perineal incision, and a bladder has been believed to have been cleared of stone by perineal incision when in reality a second stone existed which has subsequently required removal. These surgical catastrophes have been explained by the existence of three varieties of vesical pouch, the ordinary sacculus, the post-trigonal pouch, and the post-prostatic

pouch, to which I drew special attention in my paper read before the Medical Society of London in 1891. Since then, however, further experience has convinced me that there is yet another place in the male bladder, in certain forms of prostatic enlargement, where a calculus may lie out of reach of urethral instruments altogether, or to such an extent as to make it impossible to seize the stone by a lithotrite introduced through the urethra.

In a certain number of cases of prostatic enlargement the prostate forms an intravesical projection. This intravesical outgrowth may be egg-like, with the urethral orifice at the apex of the egg, while in other cases this ovoid projection may be deficient anteriorly, or anteriorly and laterally, or anteriorly and on one side only. It is never wanting posteriorly, and when deficient anteriorly and laterally we have the well known so called middle lobe enlargement. In fine, when we have anything more than middle lobe enlargement, we have lateral enlargement on one side or the other or on both, and it is between this lateral enlargement and the wall of the bladder that a pouch is formed in which I have found that a fair sized stone may lie and escape contact with a sound introduced urethrally, or if detected by the sound, prove unseizable by a lithotrite.

A The right lateral intravesical growth. B. Posterior or middle-lobe enlargement. C. Left lateral intravesical growth. D. The calculus. E. The sound.

The figure is taken from the first of the two cases I am about briefly to relate. The bladder has been cut away, leaving the interior of the vesical neck exposed to view. The intravesical prostatic growth is shown. In this case it is wanting anteriorly, and it is represented by the two lateral projections A and C, and the posterior or middle lobe enlargement B. Between the right lateral enlargement and the wall of the bladder lay the stone D, and it will be seen how difficult it is for the sound E, lying in the prostatic urethra, to be made to touch the calculus. In cases of intravesical prostatic growth, where the ovoid mass is complete all round the urethra, it is easily conceivable that a stone may lie anteriorly between the growth and the bladder wall. I have not as yet, however, met with stone in such a position. In both my cases the stones lay laterally, and caused the greatest difficulty and

anxiety, until fully demonstrated by suprapubic incision. Suprapubic cystotomy has indeed let light into many of the dark places of the bladder.

CASE I.—H., aged 69. All urine had been passed by catheter for four years. Had had renal attacks and passed calculi. There was great distress. Catheter was required every hour. Much vesical spasm. Urine contained blood and mucus. On August 18th, 1892, he was anaesthetised. Now and then the sound could be made to touch a calculus lying apparently on the neck of the bladder and on the right side. Patient and careful attempts to seize the stones with the lithotrite were unsuccessful. The patient continued to suffer severely, and on August 19th I opened the bladder suprapubically. My left forefinger readily defined a large intravesical prostatic mass, under which, in the post-prostatic pouch, no calculus could be felt, but as the finger passed round a stone was found wedged in between the right side of the intravesical prostate and the bladder wall. The calculus was easily removed with a scoop. The patient lived three weeks and lay relieved of pain, but gradually sank, apparently from an absence of any desire to live.

CASE II.—O., aged 64. This gentleman had suffered much for ten years. He had passed numbers of small calculi. The prostate was very large, the whole urethra measuring 11 inches. The most careful catheterism was followed by blood. He could not bear to have the bladder washed out. On July 3rd, 1892, the patient was anaesthetised, and with great difficulty I satisfied myself that there was a stone in the bladder, lying on the right side and close to the neck of the bladder. Sometimes the sound could touch the stone, sometimes not, and it could not be seized by the lithotrite. The stone appeared large, and in a sac or pouch. Happily I thought of putting an elastic ligature round the penis, and filled the bladder with water; the stone was then seized and crushed and entirely removed, the work being done throughout in a distended bladder. Towards the end of the year discomfort was again complained of, and in March, 1893, I examined under the influence of ether, in every way possible, with sounds, tubes, and endoscope, but could detect nothing. Feeling convinced that there must be a calculus present, I opened the bladder above the pubes in April 13th. The intravesical prostate was very large, and laterally between it and the bladder wall lay three calculi. The post-prostatic pouch contained no stone. The patient lived two years afterwards, and did not die from any vesical trouble. I believe that the first stone which I crushed lay in this lateral prostatic pouch, and that it was large enough for me to seize when the bladder was distended with water; and that the second stone, which I had to remove by lithotomy, was small enough to be completely hidden in the pouch, and to elude all instruments introduced through the urethra.

With reference to the special treatment of what I would call *lateral prostatic calculus*, as distinguished from post-prostatic calculus, a suprapubic incision satisfactorily settles all difficulties, whether the stone is only suspected, or when it can be felt but not seized by the lithotrite; but naturally there are cases where a less severe treatment is desirable, and I am convinced that the manoeuvre which I practised in my second case may occasionally be satisfactorily accomplished. The patient being anaesthetised an elastic ligature is placed round the penis, a catheter is introduced, and the bladder filled with a warm antiseptic solution. The catheter is removed and a lithotrite introduced. The elastic penile ligature effectually retains the fluid, but readily allows of the passage of the lithotrite. The wall of the bladder in this way is removed from close contact with the stone and if the pelvis of the patient is well raised, the stone may fall into a position where it can be seized by the lithotrite, or the calculus may be scooped out of its bed by a rotatory movement of the lithotrite, with its blades closed, upon its long axis. Should this fail an evacuating lithotrity tube may be introduced, an aspirator attached, and an attempt made to dislodge the stone by the suction of the aspirator through the tube, the eye of which has been brought as near the stone as possible.

Since this paper was written Mr. Codge, of Norwich, who is not surpassed by any surgeon in this or any other country as an authority on stone in the bladder, has sent me his lectures delivered in the Royal College of Surgeons in 1888. In

discussing the difficulties of lithotomy in the aged, he points out that the enlarged prostate generally projects into the bladder, and leads to the formation of deep hollows or pouches on each side of or behind and beneath the prostate in which broken fragments of stone will hide, where it is most difficult to follow them, and from which it is sometimes impossible to dislodge them by any means or by any instrument. My observations will therefore perhaps be accepted as an enlargement of these remarks, and as adding emphasis to them.

Mr. MAYO ROBSON said that cases in which vesical calculi are inaccessible by the sound occur to every surgeon. He quoted three from his own practice. In the first there were symptoms of stone, but none could be touched by the sound; after the patient had been allowed to walk about for a few days a stone was just reached. Suprapubic cystotomy was performed, and the calculus found impacted in a sacculus in front of an enlarged prostate. The second case was one in which, during the operation of suprapubic prostatectomy, three undiagnosed calculi were found in a pouch behind the hypertrophied gland. In the third case the calculus could not be touched by the sound, but could be felt by the finger in the rectum; it lay in a post-prostatic pouch with a narrow neck, which had to be slit up before extraction by the suprapubic method was possible.

Mr. BROWNE, in reply, described Mr. Robson's first case as unique.

SYMMETRICAL NECROSIS OF EACH FEMUR; UNDER NOTICE TWENTY-THREE YEARS; REPEATED REMOVALS OF DEAD BONE; ULTIMATE AMPUTATION OF LEFT THIGH; RECOVERY.

By WILLIAM NEWMAN, M.D.Lond., F.R.C.S.Eng.,
Senior Surgeon, Stamford and Rutland Infirmary.

The following are the notes of this case:

E. M., male, 21, was first seen in 1872. He had been ill five years. There was dead bone in the lower and posterior third of each femur. Large plates of dead bone were removed.

In 1874 he was well save for a small amount of discharge, and was continuously at work.

In 1880, the patient being then 35 years of age, there was evidence of pent-up matter, specially in the back of the lower third of the left thigh. Free incisions gave exit to much pus but no loose bone was found. A large irregular excavated surface was felt on the posterior aspect of the femur. He was under care for two months, and much improved.

In 1884, being now 43 years of age, and having been at work as a gardener until three weeks before, he was found to be suffering from a renewal of acute mischief, specially in the left thigh, with very serious constitutional disturbance and implication of the left knee joint. He was admitted into the infirmary on October 2nd, and amputation through the middle third of the left thigh was performed on October 24th. Repair was tedious but satisfactory. The specimen is now in the museum of the Royal College of Surgeons.

A DISCUSSION ON THE SURGICAL TREATMENT OF CYSTS, ADENOMATA, AND CARCINOMA OF THE THYROID GLAND AND ACCESSORY THYROID.

L. HENRY T. BETHUN, F.R.C.S.,
Surgeon to St. Bartholomew's Hospital.

MR. PRESIDENT AND GENTLEMEN.—Probably I betray no secret when I tell that it was not originally intended that I should open this debate. I was indeed invited to take part in it, and was pleased at the invitation. Towards the end of March I received a letter from the officers of the Section to ask me to take the place of Professor Annandale, upon whom they had relied to introduce the subject of the surgical treatment of cysts, adenomata, and carcinoma of the thyroid gland and accessory thyroids, and who had, after long negotiations,

reluctantly felt obliged to decline, as it was uncertain whether he would be able to attend our meeting. I cannot say I willingly accepted the task, for I was fairly frightened by the list of those who were to take part in the discussion, most, if not all, of whom know far more of the subject than I do; but time was growing short, it was necessary that someone should undertake to open the debate, and I agreed to do so, because it was represented to me that if I had no claim to be the wisest, at least I must admit to be one of the oldest of those set down to speak.

I mean to adhere as closely as possible to the text which our officers have decided on; but I would ask to be allowed to begin at the end of it, and to say at once that of *tumours of accessory thyroids* I know absolutely nothing. To my knowledge I have never seen a tumour of an accessory thyroid. I have certainly seen thyroid tumours lying at some distance from the thyroid gland which might have been supposed to have been developed in an accessory thyroid gland, but, when they were treated, they were found to be connected with the thyroid gland itself. I cannot but believe the frequency and importance of such tumours have been exaggerated. I do not know whether it was intended in this part of the subject to include the consideration of tumours with thyroid structure occurring in such situations as the base of the tongue. If that be so, I have, I suppose, seen more than my share; but my experience is contained in the *Transactions of the Clinical Society* (vol. xxiii, 1890, p. 118), and I have little to add to it.

Secondly, but still working backwards, I must confess to great ignorance of the surgical treatment of carcinoma of the thyroid gland. Probably it was intended to include sarcoma, and the word carcinoma may be taken to include both forms of malignant disease. Not only have I never removed a malignant tumour of the thyroid gland, but I have never seen one removed. And more, although I have seen a good many cases of malignant disease of the thyroid gland, I have never yet seen one in which there appeared the smallest likelihood of a successful radical operation. An examination of these and other museum specimens will show why this is so. Rapid infiltration, not only of the gland itself, but of the great vessels, nerves, and tubes in the vicinity of the gland, is a characteristic feature of carcinoma of the thyroid. And what is true of carcinoma is almost equally true of sarcoma, as these specimens will witness. I saw, in consultation, the patient from whom this mass was taken after death, and within three weeks of its first appearance, at least of his discovery of it, which was quite accidental. There was not, even at that early period, any chance of removing it. When he died a few weeks later (within ten weeks of the first noting of the tumour) it was, as you see it now, an immense mass, adherent to everything in the neighbourhood of the thyroid gland, and extensively ulcerated.

Last January I saw in consultation a boy, 15 years of age, whose thyroid had only been noticed to be large for about three weeks. There was general enlargement of the gland, but particularly an extremely hard and prominent mass on the right side, by which the trachea was thrust over to the left. The right side of the larynx was paralysed, the right pulse much smaller than the left. Sudden attacks of dyspnoea had several times occurred, and the tumour appeared to increase in size each day. I believed the disease to be malignant, but the rapidity of its progress and the age of the patient led me to recommend that it should be examined under an anæsthetic, in the possible chance that it might prove to be inflammatory. I cut freely into it, and found malignant disease, in which not only the thyroid was involved, but which had already extended beyond the limits of the gland and infiltrated the surrounding structures. If an operation had been performed on the very day the enlargement was first observed, there could have been no hope of a successful removal of the disease.

Although my own experience has been so unfortunate, I cannot doubt that there are occasional rare instances of malignant disease which are amenable to operation. I have read the accounts of a few such cases, chiefly in foreign literature, and I hope to hear some of our Continental confrères, whose experience in diseases of the thyroid gland is much larger than our own, speak on this important part of the subject.

Last, Sir, I come to the diseases which are set down first in your official subject for discussion, *cysts and adenomata*, of whose surgical treatment I speak with pleasure, as I have had some experience of it. The surgery of these tumours has improved very rapidly during the last ten years, and I believe the improvement is due to the more accurate knowledge which we have of them. Indeed, I would point to this as another and excellent example of the good influence of the study of pathology on the progress of surgery. Until within the last few years separate cysts and solid tumours of the thyroid gland were looked upon as rarities, and the enlargements caused by them were generally regarded as due to an enlargement of the gland itself. Now we know that almost all, if not all, partial enlargements of the thyroid gland are produced by separate and separable tumours. And we can go further than this, and say that, in the very large majority of instances, the tumour which produces the enlargement is either a cyst or an adenoma or a combination of cyst and adenoma. Here, for example, is a simple cyst in which only fluid was found. Here is a solid tumour which is formed of tissue resembling the structure of the thyroid gland. Here is a cyst in which an adenoma has grown, and here is an adenoma which contains a cyst. And here is another in which the cyst again contains a solid glandular growth. And here are larger complex tumours, in which the changes and relations of cysts and adenomata are rung in and out until the pathologist becomes confused in his attempt to assign the proper value to their component parts. But to the surgeon they all present some common features: they are innocent tumours, separate and generally easily separable, enclosed in distinct capsules, and for the most part growing in the midst of sufficiently healthy thyroid glands—glands which are certainly no more diseased than the mammary glands in which we find corresponding tumours.

It is difficult to understand why we have been so slow to become acquainted with these facts. Our ignorance of them is reflected in our nomenclature. We still speak of a cyst, simple or proliferous, of the thyroid gland as a "cystic goitre," which may be translated into "cystic enlargement of the thyroid gland;" and, of mixed solid and cystic tumours as "cystic adenomatous goitres," terms which seem to imply that there is some general affection of the thyroid gland, instead of a tumour in the substance of the thyroid gland. Who of us would speak of a fibro-adenoma of the mammary gland as an "adenomatous enlargement of the mammary gland," or of a simple or proliferous cyst of the breast as a "cystic enlargement of the mammary gland?" And who of us would think of treating a cyst of the breast by opening it and fastening its margins to the opening in the skin? Yet such terms and such treatment are regarded as suitable to cysts of the thyroid gland. For the term "goitre" suggests an enlargement of the thyroid gland, a disease of the gland, which would require the removal of a part of the gland, and surgeons have been disinclined to undertake their removal, scarcely knowing where the operation would lead; and feeling that they were only removing a part of a general disease, which might not improbably spread after the operation to the parts of the gland which were yet apparently sound.

With a better knowledge of the conditions to be dealt with a more reasonable and appropriate surgery has grown up. Cysts and adenomata are removed precisely by the same method as is employed for their removal from many other parts of the body; indeed, much more easily than from some parts of the body, on account of the readiness with which they can be separated from the tissues of the thyroid gland. I need not describe the operation further than to say that the tumour is exposed by a free incision; that the structures over it, including a layer of the thyroid gland itself, are divided until the capsule of the tumour is apparent. The capsule can almost always be readily distinguished by its bluish tint, compared with the redder colour of the thyroid gland, with which it may be confounded. From this point the knife is used as little as possible; the tumour is separated, generally quite easily, from the surrounding tissues with the finger, aided by an occasional touch with the knife or scissors to some firm band which will not yield. The hemorrhage is temporarily arrested with clamp forceps, and, after the removal of the tumour, the vessels are tied with

catgut. The wound is treated precisely in the same manner as any other wound of the neck or body. And it usually heals within five days or a week, with the exception of a tiny sinus at the lowest part, which is left by the introduction of a strip of gutta serena tissue. It is expedient to use some drainage during the first few days, in order to drain off fluids which are liable to ooze into a cavity over which it is impossible to maintain sufficient pressure.

If the operation is thus performed, I know no special difficulties connected with it; there is no reason to take special precautions against hemorrhage; no reason to treat the wound differently from any other wound; no fear of damage of any important structure.

I first took out a separate tumour of the thyroid gland (it was a fibroma) in the year 1884; and, since then, have performed the operation many times. Mr. Charters Symonds has written¹ in favour of it; but I believe that Professor Socin must be regarded as the real author, although he has not himself described it in print; for I think this is the operation which goes by the name of Socin's operation of enucleation.²

Of the dangers of enucleation, perhaps the fairest estimate may be formed by comparing it with operations for the removal of enlarged lymphatic glands of the neck.

The operation of enucleation is, so far as I have seen, applicable to all innocent tumours of the thyroid gland, whether solid or cystic. I believe I may go so far as to say that it is applicable to all partial enlargements of the thyroid glands which are due to non-malignant causes; for I am disposed to accept Mr. Berry's suggestion that almost all partial enlargements are due to the presence of cysts and cystic tumours, with perhaps, one exception—enormously capacious and deep cysts which pass far down behind the sternum. My colleague, Mr. Bowlby, described one of them at a meeting of the Clinical Society last April. It presented as an ordinary cyst well above the sternum, and he proceeded to remove it. But soon finding that it passed behind the sternum, he opened it, and, looking into its interior, could see that it was several inches deep, and that its base rested on the aorta and great vessels of the arch, which could be plainly seen pulsating through its thin wall. The enucleation was not further proceeded with; the cyst was drained, and the patient made a good recovery. Many years ago, in the out patient department, I met with a somewhat similar but even more terrible case. A woman, aged about 40, came to St. Bartholomew's Hospital with a prominent swelling of the left lobe of the thyroid gland, which I diagnosed as a cyst, and I then did, what I should not now do, tapped it with a trocar and cannula, partly to confirm the diagnosis and partly with the hope, which I should not now have, of curing it. The fluid which issued from it was deeply blood-stained. I caught it in one of the old pewter bowls which have been in use in St. Bartholomew's Hospital for centuries and which are marked inside with circular lines to show the number of ounces contained at different levels. In the course of a few minutes several ounces had escaped through the cannula, but while the tumour became no smaller the fluid became more bloody and the flow was as steady and forcible as at the first. I was surprised and wondered what to do. Having had no previous experience of a hemorrhagic cyst of the thyroid gland I withdrew the cannula and covered the opening with a dressing, which was firmly fixed with broad strips of strapping. The hemorrhage ceased and the patient went home.

But two or three days later she came back to the hospital, saying that whenever the dressing had been disturbed blood had escaped. She was admitted. The neck was prepared for operation: chloroform was administered. I exposed and

¹ Clin. Trans., 1890, xxii, 51.

² It is difficult to be sure to whom the credit of suggesting the enucleation of cysts of the thyroid gland is due. In 1893 Julliard recommended this method of dealing with cysts (*Revue de Chirurgie*, 1893, p. 385). In the same year, and in the following year (1894), the *Centralblatt f. Chirurgie* contains the same suggestion by Kottmann. And again, in 1894, the same journal contains a fuller account of the method by Burekhardt. But the application of it to mixed cystic and solid tumours, and to completely solid tumours, appears to be due to Socin. The *Korrespondenzblatt f. Schin. Aerzt.*, vol. xvi., p. 392 (1894), contains a paper by C. Garré, Socin's private assistant, in which the advantages of the method of enucleation, as practised by Socin, both for solid and cystic tumours, are fully set forth.

opened the cyst. Blood escaped freely. I enlarged the opening, hoping to discover a bleeding vessel; but, while no distinct bleeding point could be discerned, I found that the cyst passed deep down into the chest, and blood seemed to pour from every part of it, and in such abundance that I thought the poor creature must have died upon the table. I saw that no time was to be lost, and as rapidly as I could plugged the cavity with long strips of lint. Its capacity may be judged by the fact that it took nine strips, each of which was about 1 inch in width and about 12 inches in length. To my great relief the patient made a good recovery.

The so-called "hemorrhagic cysts," when they are so situated in the gland that they can be readily reached, may be removed like cysts in which no bleeding has taken place. Here are specimens of several of them. One is an old specimen from the Museum of the Royal College of Surgeons. The cyst was punctured and continued to bleed until the patient died. It serves to illustrate the need of removal, or at least of efficient plugging of such cysts. But it does not tell—what, indeed, no one has yet satisfactorily explained—why some thyroid cysts bleed so readily, and why the bleeding is continuous. The readiness with which they bleed may perhaps be explained by the frequency with which they contain soft and very vascular intracystic growths, but not the dangerous continuance of the bleeding.

To my mind, there is one great objection to the treatment of cysts and adenomata of the thyroid gland by excision or enucleation—the scar. And in the cases of young subjects I can never reconcile myself to it. At the present time we are so enamoured of our art and so pleased with our achievements in surgery that without hesitation we cut wounds which leave long scars in the neck, white and fine and perfect as scars, but cruel disfigurements in the eyes of the patients and their friends.

To avoid such scars I have, in a certain number of cases, employed Morell Mackenzie's method of treating cysts by injection. This method, which I believe to be excellent in suitable cases, has fallen much into disuse, partly because of its uncertainty, partly because it is not free from danger, and is sometimes very long-lasting and tedious; and partly because the method of treatment by enucleation is at present in vogue, for we have our fashions in surgery as in our dress and manners.

To save time, I would refer those who are not familiar with the details of Mackenzie's method to the original paper,* and would urge that the instructions which the paper gives should be closely followed. The object of the treatment is to convert the cyst into an abscess, which discharges through a small cannula until it has completely healed from the bottom. If the treatment succeeds—and it is sometimes brilliantly successful—there is really no appreciable scar. It is hardly to be recommended for hospital patients on account of the loss of time incurred, for the suppuration may continue as long as four or even six months. But where time is of little importance, and the avoidance of a scar is of primary importance, I do not hesitate to practise it.

And in order to do so with the best prospect of success and with the least danger, I have again quite recently studied the accounts of cases to discover, if possible, the conditions which have led to failure, and the causes of danger or of death: for it is said that in some cases repeated injections have failed to cure the disease, and in other cases an injection has been immediately or quickly followed by death, presumably from thrombosis or embolism, or the entrance of air into a vein, or there has been paralysis of a vocal cord and permanent affection of the voice, or diffuse suppuration has occurred in the tissues around the thyroid, and this has sometimes led to death.

I believe that failures and danger are largely to be ascribed to the treatment of improper cases, and the selection of fit cases has been rendered unduly difficult by our confused knowledge of the pathology of tumours and enlargements of the thyroid gland. From what I can learn the treatment by injection has been practised promiscuously in cases of separate cysts and cystic tumours, and in parenchymatous en-

largements of the thyroid gland. Even Mr. Berry, in his Jacksonian prize essay,† which deserves the highest praise, treats of the injection of cysts and parenchymatous goitres under one heading, and speaks as though it matters not whether an injection be made into a closed cavity or into the substance of the gland. I hold so different an opinion that, while I fearlessly treat simple cysts by injection, I would not on any account deliberately inject into the substance of the thyroid gland.

Mackenzie himself made a great distinction between the cases in which parenchymatous injections were made and those in which a solution of perchloride of iron was injected into a closed cavity. The drawing off of the liquid of the cyst through the cannula ensured the entrance of the injection into the cavity, not into the substance of the gland. Under such circumstances there is no fear of injecting into the interior of a vein, or of wounding the recurrent laryngeal nerve. And, if the cyst is continuously drained through the cannula until it is closed, there is scarcely any danger of a diffuse suppuration of the gland and its surroundings. I would not aver that the treatment of simple cysts by injection is free from danger, but I believe the danger is reduced to a minimum in the case of simple cysts. Suitable for this treatment are cysts of moderate size, cysts which are thin-walled, cysts which are simple, cysts which contain but little blood in young persons who are in good health. Conversely, strumous and delicate patients should not be treated by injection; and very large cysts and old cysts with thick walls, and cysts with calcareous walls, and compound cysts and cystic tumours should be treated by enucleation, for they are not suited to this method.

I have often wondered how far the presence of intracystic growth interferes with the successful treatment by injection. A small quantity of it probably is not an obstacle to success, for the large majority of cysts contain some growth on the inner surface of their wall. And, I suspect, that even a large quantity of soft growth would shrink up and cease to grow under the influence of injection and consequent suppuration. For pathological thyroid gland tissue, whether it produces a general enlargement of the gland, or whether it produces separate tumours, appears strangely sensitive to treatment. Faint-hearted attacks upon it, which would be almost surely resented and followed by more active growth in many tumours, are frequently successful in arresting its growth and inducing it to shrink. Yet, I would not willingly attempt to treat by injection a cyst of the thyroid which was known to contain a large mass of solid growth.

In spite of careful selection of cases for injection, it is probable that some cases will end in failure, for it is not possible invariably to gauge the fitness of the individual case. It may then be necessary to excise the disease. I should have thought that an operation undertaken under such circumstances would prove to be very difficult. I have never myself performed it, but other surgeons have done so, and their reports do not tell of greater difficulties or dangers than are met with in ordinary cases.

Of other methods of treatment of cysts and adenomata of the thyroid gland I have had no experience, nor have I any inclination to adopt them, unless a better account is given of them to-day than I have learned from reading.

It will be seen, Sir, that I have not dealt with parenchymatous enlargements of the thyroid gland, whether simple or containing cysts. To have done so would lead to long and probably disagreeable discussion. You, Sir, in your good judgment, defined the subject for discussion in such a manner as to exclude all true goitres. And I have thankfully availed myself of your definition, for it saved me from dealing with matters in which perhaps I should have gone beyond my depth.

II.—J. RUTHENFORD MORISON, F.R.C.S.,

Assistant Surgeon, Newcastle-on-Tyne Royal Infirmary.

Mr. MORISON entered upon the question of exophthalmia

* I am indebted to the authorities of this museum and of that of St. Bartholomew's Hospital for permission to exhibit specimens.

† *Clinical Society's Transactions*, vol. vii, p. 115 (1876).

† Cystic and parenchymatous goitres are so closely allied to one another in their nature, and also, to a certain extent, in the treatment suitable for them, that it has been thought advisable to treat of both under a common heading. "a, Sir J. G. Simpson's tapping; b, tapping and injection; c, Simon's method; d, M. Mackenzie's method."

goitre, operations on which appeared, according to recent experience, to have been very successful. Four cases, however, which he had recently seen in the practice of four different surgeons, had terminated unfavourably. Upon the question being raised, the President decided that exophthalmic goitre did not come within the scope of the discussion.

III.—W. W. KEEN, M.D., LL.D.,

Professor of Surgery, Jefferson Medical College, Philadelphia; Surgeon to Jefferson College Hospital.

PROFESSOR KEEN drew attention to the fact that on the Continent of Europe thyroid operations were done without the use of anaesthetics except in children under 15 and in very nervous patients. He was much struck with the very slight pain of the operation. When no anaesthetic was given there was less hæmorrhage since the respiration was less embarrassed, and the patient did not cough when coming to. Also during the ligation of the inferior thyroid artery the patient was induced to talk in order that it might be seen whether the recurrent laryngeal nerve was included in the ligature. Professor Kocher, whose practice he was describing, made a transverse incision convex downwards so as to get at the thyroid better, and leave a well-concealed scar. Dr. Keen thought the scars in Mr. Butlin's cases very slight. He suggested the use of Halsted's subcuticular suture for the purpose of obviating unsightly scars. This is effected by a moderately stout silver wire carried backwards and forwards across the face of the cavity beneath the skin. The wound is slightly puckered at first, but when the suture is removed, in some cases after as long as three weeks, almost no visible scar is left. There is no invasion of the ligature by the epidermal streptococci. Dr. Keen's own personal trouble in these cases was hæmorrhage. Much attention is paid to this in Switzerland, every bleeding point (artery, vein, or tissue) being seized in pressure forceps and subsequently, if necessary, ligatured. Thus not more than 2 ozs. of blood are lost during the operation. Professor Kocher, after his first incision, cuts right down to the tumour, tying every source of bleeding. He then goes for the tumour, commencing his extirpation at the upper part, which he can often wipe clean from the surrounding tissues. He next ties the superior thyroid artery and vein, and then goes right down to the thyroidea ima. He finally feels for and ligates both inferior thyroid arteries in succession, then removes the tumour. Dr. Keen assented to Mr. Butlin's statement that in diseases of the thyroid the treatment should rest on a pathological basis.

IV.—CHARTERS J. SYMONDS, M.S., F.R.C.S.,

Assistant Surgeon, Guy's Hospital.

MR. SYMONDS had had 44 successful cases of thyroid operations, of which 29 had been on cysts and adenomata. Carcinoma of the gland was inoperable, but where there was compression of the trachea indicating tracheotomy, it was a surprising fact that almost no hæmorrhage attended the incision through the growths. For cysts he employed the median incision, which allows the surgeon to get at any tumour of a lobe. Professor Kocher is troubled by hæmorrhage because he resects the gland before approaching the tumour, which is unnecessary in 99 cases out of 100, whereas dissection of the gland off the cyst is unattended with hæmorrhage. "Hæmorrhagic cysts" are those which have vascular growths from their walls. If the wall of a cyst is white it can be enucleated without hæmorrhage; if purple and vascular, blood rushes out when it is punctured. The hæmorrhage is alarming for a moment, but as the cyst wall is very thin the finger can be inserted and the whole tumour turned out almost instantaneously. The cavity is plugged with a sponge and the bleeding stops at once. With regard to the question of anaesthetics, ether leads to free hæmorrhage, which is not present when chloroform or A.C.E. mixture is used. The wound should be drained for twenty-four hours but no longer. Substernal cysts are very grave but, if thick-walled, may be operated on with confidence. As to injection, pure cysts do well, those with solid growths badly, for where there is a growth the wall is thin, and suppuration is liable to extend through. The great objection to injection is the frequent impossibility of

diagnosing between solid and cystic growths. With regard to the scar, Mr. Symonds makes a median one as near to the sternum as possible. He finds that a white-walled tumour can be punctured and removed through a $\frac{1}{4}$ inch incision without hæmorrhage.

V.—A. W. MAYO ROBSON, F.R.C.S.,

Senior Surgeon, Leeds Royal Infirmary; Professor of Surgery, Yorkshire College, Leeds.

MR. MAYO ROBSON, on the whole, supported Mr. Butlin. He had changed his views since reading Mr. Symonds's paper on the subject. He had no experience of accessory thyroid tumours. In regard to malignant disease he considered it but rarely amenable to operation. The dyspnoea was very hard to relieve, but intubation had been very successful in one case in which tracheotomy was impossible. He had sometimes had difficulty in enucleation, and had even had to remove a whole lobe. He had tried subcutaneous suture and found that it minimised the scar, whence Mr. Butlin's objection to incision was not very important. Ether as the anaesthetic produced great venous congestion with increased hæmorrhage and dyspnoea, but chloroform and A.C.E. mixture were not open to this objection. A very good method was to anaesthetise the patient during the skin incision, and then to allow him to come to. He had twice done tracheotomy for dyspnoea during an operation on the thyroid, and had made a point of suturing the trachea immediately after the operation, avoiding the difficulty which Professor Kocher finds in this procedure.

VI.—JAMES BERRY, B.S., F.R.C.S.,

Surgeon, Royal Free Hospital.

MR. BERRY said: I think it ought to be clearly borne in mind that the great majority of cases of goitre that we meet with in practice require no surgical treatment. I cannot help thinking that of late years operations for goitre have been performed a little too often, sometimes when they were really not necessary. In my own practice I operate only on a small minority of cases that come under my notice. There should, in my opinion, always be some definite reason for the operation other than the mere presence of a tumour. That reason in most cases is dyspnoea. I find from my notes that my operations for the removal of goitre have been 36 in number, and that in 31 of these cases the operation was undertaken on account of dyspnoea, often dyspnoea of a severe and paroxysmal nature. In one case dysphagia was the cause of operation, in another a septic sinus that had followed injection of a large cystic goitre performed a year previously at another hospital; in 3 cases only have I operated merely for deformity; in 2 of these the patients were young ladies exceedingly anxious to be rid of a deformity which prevented them from wearing low dresses.

There are two main classes of operation by which removal may be effected, and these two classes are essentially different. One is extirpation of a part of the gland together with its glandular capsule, an extraglandular operation; the other is enucleation of a localised tumour, whether cyst or adenoma, from within the thyroid gland in which it lies embedded, an intraglandular operation.

I should like here to refer to a remark made by Mr. Symonds, and to express the opinion that these localised tumours, however superficial they may appear to be, really are always covered by a layer of true gland tissue. The latter is often so much thinned and atrophied by pressure that the tumour appears to be uncovered by thyroid tissue; a layer of such tissue nevertheless always exists, and its presence can be and has been repeatedly demonstrated by the microscope. In operating by enucleation it is very important that this layer be penetrated, so that the actual surface of the enucleable tumour be exposed. The shelling out is then effected far more easily and safely.

It is often a difficult matter to decide which of these two operations, extirpation or enucleation, is to be preferred for a given case. Enucleation is to be attempted, I venture to think, in those cases in which there is a single well-defined tumour on one side of the neck only. It is, in the main, correct to say that unilateral goitres are capable of treatment by enucleation, but we must not forget that there are some

few cases of strictly unilateral goitre in which enucleation is wholly inadmissible and impossible to perform. These are chiefly the cases of large solid fibro-adenomatous tumours involving the whole of one lateral lobe of the gland, and which are met with chiefly in middle-aged women. In one case of this kind I successfully removed by extirpation, not by enucleation, a tumour which weighed 19 ounces. Subsequent examination of the tumour showed that there was no intraglandular capsule, and that consequently enucleation would have been an impossible operation.

Another class of unilateral tumours unsuitable for enucleation comprises those cases in which one lobe of the gland is occupied by a number of cystic or solid tumours, the opposite lobe being healthy or nearly so; such cases are, however, comparatively rare.

The most characteristic feature of a tumour capable of removal by enucleation is, in my opinion, its shape. The more nearly globular the tumour the more likely is it to permit of enucleation. Tumours that preserve exactly the normal pyriform shape of the gland are seldom suitable for enucleation. Smoothness of surface is another point of some importance. Very irregular nodular tumours are seldom suitable for enucleation, since the irregularity generally betokens the presence of multiple cysts or adenomata, and multiple tumours are not as a rule removed with advantage by any intra-glandular operation.

The position of the tumour is a point of some importance, since unilateral tumours high up in the gland, although a great deformity, rarely cause serious dyspnoea unless very large indeed. Of unilateral tumours it is those that are situated low down in the neck, and especially in the upper opening of the thorax, that most urgently demand removal. To illustrate this point I have selected a typical case out of several that have come under my notice. A man, aged 53, was admitted into the Royal Free Hospital under the care of my medical colleague Dr. Sainsbury, suffering from extreme paroxysmal dyspnoea, for which at first no cause could be found. I show you a cast of the neck taken before operation, and you will see that there is no visible swelling. On examining the root of the neck a slight swelling could be felt just above the sternal notch, evidently the top of a substernal goitre. The man's condition being desperate, I cut down upon the swelling, and succeeded in pulling up from behind the sternum and removing by enucleation the tumour now shown to you, and which is about as large as an ordinary tennis ball; about two-thirds of it is solid, the remainder cystic. The wound healed throughout by primary union, and the man left the hospital on the seventeenth day completely cured.

A few words in conclusion upon the complications of operations upon goitre. By far the most serious are sepsis and hemorrhage. Of the former it is not necessary to say much. It is of course all important that the operation should be strictly aseptic, and I have pleasure in stating that I have never lost a patient from suppuration or other septic complication following an operation for goitre. In one case some suppuration was followed by a slight attack of pneumonia, and caused much anxiety for about three weeks, the patient then making an excellent recovery; this was a case of extirpation of a large bilateral parenchymatous goitre. Hemorrhage, especially venous hemorrhage, I have found occasionally to be troublesome. This has especially been the case with some enucleations. I consider that hemorrhage is less serious in cases of extirpation, because every vessel should be seen, and tied or clamped before it is cut. In all my later cases of extirpation, the loss of blood has been quite trivial, and I hardly ever see spurting from any artery except the most minute. With enucleation the case is somewhat different. In the great majority of cases there is very little bleeding, but sometimes, especially in the case of large tumours and tumours in young subjects, the hemorrhage may be very alarming. It is best dealt with by rapidly completing the enucleation, and then temporarily drawing the bottom of the wound forward with a pair of forceps. Of wound of the recurrent nerve, a grave complication by no means unknown, I have fortunately had no personal experience.

An anonymous donor has presented to the Royal British Nurses' Association the sum of £100.

VII.—O. B. KEETLEY, F.R.C.S.,

Senior Surgeon, West London Hospital.

Mr. KEETLEY had twice operated in cases of malignant disease, and three times without an anæsthetic. In one of the latter cases the tumour projected anteriorly in front of the chin, reached downwards to the sternum and outwards to the ear on either side, overlapping both sterno-mastoids by numerous processes. Anæsthesia was only employed during the division of the skin. A flap was turned back, and the tumour occupied 3 hours in removal, during which the patient was under no sort of restraint whatsoever, and did not raise any objection. The only time that any pain was felt was in the process of lifting the tumour up from behind the sternum. Another operation was performed without an anæsthetic owing to the patient taking chloroform very badly. Malignant disease came in another category altogether. Theoretically the growth must at one time be encapsuled, and should therefore be favourable for removal if only diagnosed early enough. The difficulty at present was the early diagnosis of malignancy, but surgeons who operated frequently on the thyroid would no doubt often find cases of early malignancy. The advance in our knowledge of this subject was due to the improvement of clinical pathology. Mr. Keetley considered that there should be no hesitation about lengthening the incision if necessary. Drainage was not required, but the serum might be let out later if necessary by means of a probe. He concluded by expressing his decided objection to any method of treatment which had for its object the setting up of suppuration.

VIII.—A. E. J. BARKER, F.R.C.S.,

Surgeon to University College Hospital; Professor of Surgery, University College, London.

Mr. BARKER recounted two cases of malignant disease of the thyroid which he had successfully treated by operation. In the first the tumour had been pronounced malignant six years before the operation by the late Mr. Hulke and Sir William Savory. Mr. Barker made an incision 13 in. to 14 in. long, and enucleated the growth together with infected glands behind the clavicle as far as the apex of the pleura. The wound healed by first intention. There was recurrence in a gland two years after the operation. This was removed, and the patient was quite well last Christmas, six years after the original operation. The second case was one in which the right side alone was affected. The right scalenus anticus muscle had to be removed, and the phrenic nerve turned aside. The wound healed by first intention, and there was no recurrence five years later, though the patient suffered from urgent dyspnoeic attacks suggesting mediastinal growths.

IX.—JORDAN LLOYD, F.R.C.S.,

Surgeon, Queen's Hospital, Birmingham, and Birmingham and Midland Hospital for Children.

Mr. LLOYD had had two cases in which enucleation was very difficult, the cysts being associated with solid tumours. He had formerly disbelieved in the occurrence of severe hemorrhage in these cases, but had since had two very severe examples. In one case of a woman aged 60, there was great dyspnoea, and the patient's condition was very grave. An ice-bag was applied to the tumour, and the patient propped up in bed. Seven or eight days later Mr. Lloyd excised the tumour with success. He considered that the malignancy of Mr. Barker's cases must have been very different from that usually met with in thyroid tumours, which, as a rule, progressed very rapidly, and attached themselves very firmly to surrounding structures. There might be besides sarcoma and carcinoma a third kind of malignancy peculiar to the thyroid, and Mr. Barker's cases were possibly examples of this. Mr. Lloyd thought Mr. Butlin's objection to enucleation on account of the scar unfounded, and believed injection to be much too dangerous to practise, leading, as it sometimes did, to fatal results. He had four or five times operated by horizontal incisions low down in the neck, thus obviating the scar.

X.—THELWALL THOMAS, F.R.C.S.,

Assistant Surgeon, Royal Infirmary, Liverpool.

Mr. THOMAS described two cases of accessory thyroid tumours.

The first was in a woman aged 35, who had lumps behind the sterno-mastoid near the ear, and one under the angle of the jaw. These were quite unconnected with the thyroid, but on removal were found to be composed of normal thyroid tissue, one containing a small cyst. The second was in a woman aged 29, who had had a little lump in the posterior triangle above the clavicle ever since she was quite a little girl. It consisted of thyroid tissue with cysts. The thyroid itself was normal. Mr. Thomas agreed with the difficulty of diagnosing cysts from solid tumours in the neck, but had a great objection to running needles into them. He called attention to the lines of cleavage in the skin, one of which ran right across the middle line of the neck. If incisions were made parallel to the lower jaw the skin would not stretch subsequently.

XI.—R. C. CHICKEN, F.R.C.S.,

Surgeon, General Hospital, Nottingham.

Mr. CHICKEN had first operated on the thyroid in 1886, when the current of opinion was contrary to surgical interference. He treats all tumours by enucleation, and believes that the difficulties in this are usually caused by the previous application of strong medicaments to the skin. He has only met with one case of hæmorrhage; in this he could not enucleate the tumour, but had to tie its pedicle. In some large unilateral growths he removes the isthmus of the thyroid, after which they atrophy. The largest cyst he had met with he tapped and drained with perfect success.

XII.—C. W. CATHOART, M.B., O.M., F.R.C.S.,

Assistant Surgeon, Royal Infirmary, Edinburgh.

Mr. CATHOART simply desired to draw attention to the gradation in malignancy between different thyroid tumours, there being an intermediate stage between the malignant and the non-malignant.

Mr. BUTLIN'S REPLY.

Mr. BUTLIN thought that the account given of Professor Kocher's procedure showed that we are much ahead of Continental operators in thyroid surgery. He had never had to ligature the inferior thyroid artery, and was not accustomed to more than 2 drachms of hæmorrhage. He thought that the scar of the transverse incision rather recalled a cut throat, and considered it a misfortune when he punctured a cyst during its removal. He had only met with one adherent thyroid tumour, and in that case there was curiously little bleeding, the vessels having been destroyed by the adhesions.

ABSTRACT OF NOTES UPON A SERIES OF SEVENTY OPERATIONS FOR THE REMOVAL OF TUMOURS FROM THE URINARY BLADDER.

By E. HURRY FENWICK, F.R.C.S.,

Surgeon to the London Hospital.

THE value of an intelligent and skilful electric cystoscopy in determining the presence and the character of vesical tumours and in indicating the propriety of removing them is amply borne out by the results obtained in this series. The following points are submitted for discussion:

BENIGN TUMOURS.

Although benign papillomata of the urinary bladder are characterised by the symptomless appearance of blood, causelessly and intermittently, in normal urine, yet there are some papillomata which evoke symptoms which markedly resemble stone in the urinary bladder. This deviation from the classical is due to the length of the pedicle or stalk, which favours the free excursion of the tumour and allows it to get swept into the orifice of the bladder, and to act as a partial or as a complete plug. Benign papillomata therefore readily fall into two divisions, the non-obstructive and the obstructive. Of these the former are by far the more common. I hold very strongly that the calculus sound should not be employed in either class. In the non-obstructive group the

symptoms are so definite and so dissimilar to stone that its employment in males under 50 years of age is not only useless but detrimental. After 50 years of age, cases are encountered in which small, smooth uric acid stones, lodging behind an upraised prostate, produce symptoms similar to those of benign growth, and the sound permissible. In the obstructive group of papillomata a cross-examination of the onset symptoms will permit of a diagnosis of pedicled tumour being made rather than that of stone, and a distinct danger is avoided if the patient's bladder is not interfered with. In the obstructive group backward renal pressure has already been exerted by the plugging; there is always more or less residual urine, and the sound or the catheter is extremely prone to induce cysto-pyelitis.

In all cases in which a vesical growth is suspected it is much wiser to cystoscope in a period of calm between the attacks of hæmaturia, and to arrange that the bladder be full of urine at the time. In all cases of growth, if the bladder has not been meddled with, the urine in these intervals will be seen to be quite clear, and the growths are exhibited to their best advantage. Failing a cystoscopy, a fingertip sized opening suprapubically is the best method of examination.

OPERATION.

The best results have been obtained in cases which have not been sounded or catheterised. I am sure that the true surgery of the disease is to make the operation coincident with the examination. All those cases in which the operation has been performed immediately after the cystoscopy have done well. These remarks apply equally well to operations for the removal of stone from the bladder.

ROUTE.

Women seem more prone to produce pedicled papillomata than men. Many of these growths can be cleanly removed through the dilated urethra, either with forceps or through cannula, but the surgeon should always obtain permission to operate through the vaginal septum or suprapubically in case he should find that the base is extensive or the pedicle very thick.

In man, the only certain and surgical route is the suprapubic.

It is advisable in every case of subcapsule or pedicled growth to remove the base cleanly either by cutting or by crushing and cutting. The curette is only indicated in large sessile patches or secondary minute patches. The bleeding from the base of the ablated tumour should be arrested before the patient leaves the table. The best means to effect this is probably a silk ligature left hanging out of the bladder or the application of iron through a Keith tube. I have reason to believe that the munching or squeezing of the healthy mucous membrane in the neighbourhood of the growth fosters the appearance subsequently of growth in the traumatised areas. It is questionable whether the removal of a small sessile patch is advisable in the male before 32 years, as the rate of increase of sessile patches is often very slow. To determine this question, the cystoscope is of the utmost value. The longer the history of a non-obstructive tumour the denser will its structure be found to be.

MALIGNANT GROWTHS.

The opinion I expressed in 1893 regarding operative interference of malignant growth has not been modified by wider experience. The hard slow-growing single button of carcinoma can be removed with a fair prospect of successful delay of the course of the disease, provided that the base and submucous tissues beneath the tumour be removed with the knife. Munching the surface of a carcinoma and leaving the base is tantamount to an increase in the rapidity of its growth. Malignant growths situated on or near the trigone do not repay removal, and always resent interference. If they obstruct, they had better be treated by suprapubic drainage. All infiltrating growths as detected by rectal, or by bimanual examination under ether, all multiple or "contact" growths as discovered by the cystoscope are inoperative. Small, single, indolent malignant growths may be removed even when they have so far advanced as to become glued to the muscle coat, provided that the entire thickness of the subjacent bladder wall be resected with them. This

is, of course, only feasible in the anterior, lateral, or posterior wall of the middle and upper zones. When the peritoneum is included in the ablation, free drainage of the bladder must be maintained in order to afford the bladder wound time to heal. As an example of the value of resection, I may mention that I ablated a large piece of the left lateral wall of the bladder for epithelioma two years ago.³ The patient is still at work and in good health.

RESULTS.

These 70 ablations include recurrences. I have had 5 deaths, 2 as the direct result of the operation.³ The remaining 3 deaths occurred in carcinomatous cases at or about the third week after the operation, the patients dying of renal complications.

A NOTE ON THE EMPLOYMENT OF DIPHTHERIA ANTITOXIN AS A CULTURE MEDIUM FOR THE DIPHTHERIA BACILLUS:

AND ON SOME PRACTICAL POINTS IN CONNECTION WITH THE PREPARATION OF DIPHTHERIA ANTITOXIN.

BY

A. E. WRIGHT, and SURGEON-MAJOR D. SEMPLE,
M.D., M.D.,

Professor of Pathology,
Army Medical School, Netley.

Assistant Professor of Pathology,
Army Medical School, Netley.

The bacteriological diagnosis of diphtheria is at present almost exclusively in the hands of bacteriological specialists. The practitioner takes a portion of the diphtheritic membrane, or a swab which has been in contact with the diphtheritic throat, and sends it in for diagnosis to a central laboratory. Cultures are there made from the diphtheritic material upon tubes of blood serum; these cultures are kept at blood heat for twenty-four hours; the bacteria which have grown are then examined microscopically, and the result is reported to the practitioner. This deputing of the task of making the bacteriological diagnosis has been found to work well in practice. But there are numerous occasions when, either owing to distance from a laboratory or other causes, this course can not be adopted. In such cases the practitioner must himself undertake the bacteriological diagnosis. He has hitherto been deterred from doing so by the fact that blood serum, which constitutes by far the best culture medium for the diphtheria bacillus, is not easily obtained.

We propose to show that this difficulty can be easily overcome. The practitioner who is dealing with diphtheria will, we may take it generally have beside him a supply of antitoxic serum or plasma. Now, in this antitoxic serum or plasma the practitioner has at his disposal as good a culture medium for diphtheria as the serum when it is derived from a non-immunized animal.

The method by which the culture medium can be prepared is as follows. A small quantity of the antitoxin (half a teaspoonful will amply suffice) is to be poured into any clean—but not necessarily sterile—small wide-mouthed bottle. The bottle is to be brought into the horizontal position, and the albuminous substances of the serum are to be coagulated in this position so as to adhere to the side of the bottle. This may be conveniently done by laying the bottle sideways over the mouth of a steaming kettle. The bottle is to be removed as soon as the serum is firmly coagulated. Any water of condensation that may have accumulated is to be poured off, and the culture medium is to be allowed to cool down. It is then to be inoculated by passing a stout wire or glass rod which has been brought in contact with the diphtheritic throat lightly over its surface. The stopper is then to be replaced, and the bottle is to be kept as nearly

as possible at a blood temperature. If a higher temperature cannot be obtained, the temperature of an inside pocket will generally suffice. The microscopical examination may be undertaken after 24 hours have elapsed. The material for examination may be obtained by lightly scraping the surface of the culture medium with a platinum needle.

This method of preparing a culture medium from antitoxic serum or plasma may also be employed in the laboratory. There will probably, in every laboratory in which antitoxin is prepared, be enough leavings of antitoxic serum or plasma to make it unnecessary to employ serum derived from other sources. About 1 to 2 c.c.m. of the antitoxin suffice for each examination, and the serum may conveniently be coagulated in a Petri's dish held over a beaker of boiling water.

In this connection it may not be out of place to advert to the following practical points in connection with the preparation of diphtheria antitoxin:

1. There are certain advantages of convenience in employing the plasma instead of the serum of immunised animals as an injection material. (a) A larger yield, often over 65 per cent. of the blood volume, of an equally effective antitoxic fluid is obtained and this amount is not dependent upon the degree to which the clot contracts. (b) Antitoxic plasma can always be obtained perfectly free from red blood corpuscles. The blood corpuscles of horse's blood sediment very readily, and there is no need to disturb them when the antitoxic fluid is siphoned off.

There are no disadvantages to be balanced against these advantages. Experience has shown that no danger whatever is to be apprehended from the injection of plasma. Urticaria is an exceedingly rare sequel. The antitoxic plasma is readily prepared by leading off the blood from the horse's vein into a little citrate of soda dissolved in normal salt solution. An addition of 5 grammes of citrate of soda for every 1000 c.c.m. of blood is all that is required, provided that the tube through which the blood is led into the receiving vessel reaches quite down to the bottom of that vessel, so as to ensure complete mixture.

2. The easiest method of siphoning off the antitoxic plasma from the layer of red blood corpuscles appears to be the following.

A glass tube is to be bent into the shape of a U in such a manner as to leave one limb considerably longer than the other. Near the extremity of the longer limb another glass tube is to be fused on at an acute angle. To this side tube a piece of india-rubber tubing is to be attached. The other end of this india-rubber tube is fitted with a mouthpiece plugged with cotton wool. A siphon will thus have been formed which can be started by exhausting the air in the side tube. A tap or a piece of india-rubber tube fitted with a pinchcock is fixed at the end of the long limb of the siphon. This completes the arrangement.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

A CASE OF BREACH-PISTOL OF GUN IN ORBIT: REMOVAL: RECOVERY.

TANG SHAN, Chinese farmer, 31 years of age, was injured in the face by the bursting of a shot gun. After being for upwards of two months under the treatment of native practitioners, he came to me on December 4th, 1901.

I observed a cicatrix on the right side of his nose, and above this a sinus still unhealed, the orifice of which involved the inner canthus of the right eye, and extended downwards and inwards for about a centimetre. The sight of the right eye was entirely lost, and the anterior surface of the globe was so uniformly red that the cornea could hardly be distinguished from the surrounding conjunctiva. There was no perceptible enlargement or protrusion of the eyeball, and it did not appear to have sustained any mechanical injury or loss of tissue. The ophthalmia and keratitis were possibly caused by the irritating substances applied by the Chinese doctors to the wound.

The sinus on the side of the nose gave exit to a continuous

¹ *Lancet*, 1901, 1902, 1903.

² *British Medical Journal*, 1901, 1902, 1903.

³ Where antitoxin cannot be obtained, hard-boiled white of egg, which was proposed as a culture medium by Takamizawa, will serve as a very fair substitute. The culture medium may be prepared from the raw white of egg by the same method as that here recommended for the preparation of the nutrient medium from the antitoxic fluid.

discharge of slightly putrid pus, and the patient complained of continuous headache and occasional dizziness, which interfered with his work. The pain was referred to the right frontal and temporal regions, and the skin on this part of the head had a slight blush, but there was no superficial tenderness.

The patient had been told by his native doctors, and he believed it himself, that there was no foreign body in the wound; but on probing it I easily recognised the lower edge of a hard metallic substance at a depth of about 1 inch posteriorly from the orifice of sinus.

Being unable to obtain any reliable information as to the probable size or shape of the object, I cautiously made several attempts to remove it through a slightly enlarged opening, but without success. I therefore continued the incision along the side of the nose to the nostril, thus laying open the right nasal cavity; then, seizing the foreign body with a pair of strong forceps, I with difficulty removed the complete breech-pin of a Chinese gun. Its size and shape are accurately represented by the accompanying drawing.

The breech-pin measures a little over 3 inches in length, and weighs 2½ ounces, or 75.6 grammes. It had evidently lain at the back of the orbit, inclined upwards and slightly backwards from its point of entrance, at an angle of about 45 degrees. On its removal the headache was at once relieved and did not return. In ten days the wound was perfectly healed and the patient went back to his work.

A somewhat similar case, but which terminated fatally, is recorded in the *American Journal of Medical Science* of July, 1882.

Fatshan, South China.

CHARLES WENTON, M.D., M.Ch.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

F. H. CHAMPNEYS, M.A., M.D., President, in the Chair.

Wednesday, October 2nd, 1895.

SPECIMENS.

DR. WILLIAM DUNCAN: (1) Ruptured Tubal Gestation; (2) Double Pyosalpinx Complicating Pregnancy.

THE VARIATION IN HEIGHT OF THE FUNDUS UTERI ABOVE THE SYMPHYSIS DURING THE PUERPERIUM.

Drs. T. G. STEVENS and W. S. A. GRIFFITH read this paper, which was intended to demonstrate the importance of recording by measurement "charts of involution" during the puerperium. It had been for the most part drawn up by Dr. Stevens, and was the result of observations by Dr. Griffith and Dr. Stevens at Queen Charlotte's Lying-in Hospital. The method of measurement was first described, with the precautions necessary to avoid errors, and the method of recording the measurements on the ordinary temperature charts. The measurement was the height of the middle of the fundus above the symphysis. The sources of error were: (1) Distension of the bladder; (2) distension of the rectum; (3) distension of the small intestines; (4) prolapse of the uterus; (5) abnormally high uterus; (6) unusual bulk of uterine muscle; (7) retroversion of the uterus; (8) excessive lateral obliquity of the uterus. The pathological conditions which interfered with the involution of the uterus, and therefore with the descent of the fundus, were: (1) Retention of portions of placenta and membranes, and of blood clots and lochia; (2) putrid decomposition within the uterus. (There had been no septic cases to study.) Charts illustrating normal involution and its variations, and pathological conditions were given, and their value in indicating, even

before any rise of temperature, putrid decomposition, was demonstrated. Reference was made to the work of Serdudoff,¹ and the valuable work of Barbour² had not been overlooked.

Dr. McCANN wished to mention as a source of error in such measurements marked anteversion of the uterus. With regard to the influence of suckling, he had found that in women who had no milk involution was rapid, while in those who had milk and nursed their children involution was rapid for the first few days, the rapidity diminishing later, probably owing to the stimulus from the breasts decreasing. The effect of prematurity of labour as a cause of delayed involution was noted, and prolonged labour delayed involution for the first days. It was important to determine on what day the uterus became a pelvic organ, for on this rested to a large extent our opinion as to when a puerperal woman should assume the erect posture. Textbooks stated that at the tenth day a patient ought to leave her bed. Dr. McCann thought that a more scientific method was to investigate the position of the uterus before giving an opinion. He gave some statistics showing the dates on which the uterus became pelvic in 1-pars and multiparae respectively.

Dr. STEVENS said in reply that with regard to Dr. McCann's query as to extreme anteversion being a source of error in measuring the uterus, the dorsal position assumed for measuring purposes would tend to correct that displacement unless the anteversion were so extreme as to make the fundus lie entirely behind the symphysis pubis.

Remarks were made by Drs. GRIGG and GRIFFITH.

CERTAIN MICRO ORGANISMS OF OBSTETRICAL AND GYNÆCOLOGICAL INTEREST.

Dr. G. D. ROBINSON read a paper on this subject, in which he pointed out the fact that in fatal cases of puerperal sepsis the streptococcus pyogenes was constantly found in the blood and tissues. He mentioned some of the circumstances which caused increase or diminution of virulence in this organism. Normally after labour the uterine cavity was known to contain no microbe; but in cases of puerperal sepsis many micro-organisms of different sorts were found both in the uterine cavity and in the substance of the decidua. Of these the streptococcus pyogenes appeared alone to be able to pass through the uterine walls along the veins and lymphatics, and so to cause a general infection. This microbe might in these cases cause death without producing any obvious lesion, and 3 cases were cited. Much more frequently the streptococcus set up suppurative in various tissues. Sometimes this microbe produced false membranes on the peritoneum or genital tract, with or without suppuration. Two cases were cited. Late in some cases of phlegmasia dolens the streptococcus pyogenes had been found in the clots plugging the veins of the uterine walls and broad ligaments (more rarely in the clots in the iliac veins), and even infiltrating the vein wall itself. Dr. Robinson next pointed out the supposed connection of the bacillus coli communis with various inflammations (usually suppurative) of the human body. He quoted a case in which a woman four months' pregnant had intestinal obstruction from retroversion of a gravid uterus. Abortion occurred four days after reposition, and was followed in a few hours by fever and diarrhoea, which continued until the death of the patient five days later. During life pure cultures of the bacillus coli communis were obtained from the uterine discharge, and after death these were obtained from the uterine cavity, peritoneum, and heart's blood also. Attention was next drawn to the gonococcus, its appearance as seen in gonorrhoeal pus or in pus cultures, and its relation to gonorrhoeal discharges, and the situations in which it had been found.

The PRESIDENT said that the paper was valuable as a summary of the present state of knowledge of a subject which most had to take second-hand. One fact with regard to the comparative impermeability of the decidua to micro-organisms struck him as being important practically. It might not always be safe to curette the uterus when its contents were septic. In one such case within his own knowledge infection seemed to follow curetting, and a fatal result followed.

¹ *Edin. Med. Journ.*, May, 1876 p. 985.

² *The Anatomy of Labour*, 1885.

Dr. ROBERTS asked the author if he knew the exact clinical appearances in the cases of white leg referred to in the paper, for the term "white leg" was made to include many forms. Dr. Roberts believed that the definite white brawny legs were generally septic with a very early onset of symptoms, and often with distinctive pelvic signs (parametritis, etc.), while the commoner thrombotic leg came on generally later—namely, about the tenth to the twelfth day. He believed that high temperature did not necessarily mean sepsis. He also asked the author if anything was known of cultivations of the micro-organisms found in the brawny legs, and whether the *S. pyogenes* was invariably found. He suggested that the bacillus coli communis was the cause of some cases of suppuration in ovarian tumours and extrauterine sacs, which on account of some reason for lowered vitality became permeable to these organisms. If the *S. pyogenes* were the only organism which had the power of penetrating the deeper layers of the uterus and the lymphatics, he thought that the removal of the superficial layer by curetting should be attempted, combined with antiseptic treatment of the uterine cavity.

After some remarks by Dr. GRIGG and Dr. McCANN, Dr. ROBINSON, in reply, said he was unable to give any information as to the colour of the skin in the fatal cases of phlegmasia dolens, as this point had not been noted in the report. He thought that culture experiments on living patients suffering from phlegmasia dolens would be of no value, since it had been demonstrated that the secondary clots in the affected limbs rarely contained streptococci, even in those fatal cases of the disease in which numerous organisms were found in the primary clots and walls of the vessels. He had experienced the usual difficulty in separating the gonococcus from other microbes. According to his experience the best method of doing this was by making plate cultures with a mixture of blood serum (human, ox, or horse), and agar-agar in the manner recommended by Wertheim and others.

SPECIAL MEETING.

The PRESIDENT announced that the next meeting of the Society would be made special for the purpose of considering some recommendations of the Council regarding the Society's laws.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A. SYMONS EGGLE, M.B., President, in the Chair.

Friday, October 4th, 1895.

THE DEATH OF M. PASTEUR.

MR. KENTLEY moved a vote of condolence with Mme. Pasteur.

PRESIDENT'S ADDRESS.

The PRESIDENT delivered an address on the Advantages of Oxidation. He remarked that a large portion of the oxidation processes occurred in the muscular system, and mentioned the series of changes taking place in an active muscle, the sense of weariness being attributed to the accumulation of incompletely oxidised products. The grave consequences of partial arrest of oxidation processes were alluded to, and stress laid on the presence in the system of leucomaines as a result leading in some cases to a morbid condition, which might best be termed "leucomainemia." Reference was made to the work of Bouchard and others, and it was pointed out that in chlorosis, gout, etc., there was evidence of insufficient oxidation, with excess in the urine of leucomaines and other products of incomplete oxidation. The train of symptoms generalised under the term "neurasthenia" were attributed to suboxidation. The method of von Poehl for the detection of leucomaines in the urine was described. It was shown that in melancholia, etc., the symptoms varied *pari passu* with the amount of precipitate by von Poehl's process. The parallelism between the prodromata of acute fever and some of the symptoms of functional neuroses was attributed to like causes being in operation, though not of common origin. Comparison was drawn between symptoms of cinchonism and those of coprostasis, the poisons in both interfering with the oxidation process. It was suggested that much of the value of animal extracts might be assigned to their potency as oxidising agents. The value of exercise and other therapeutic

means for promoting oxidation was detailed and illustrated by the narration of cases.

Dr. LAUDER BRUNTON laid stress on the value of apparently theoretical observations, and pointed out that many of Pasteur's most practical results arose therefrom.

Dr. CAMPBELL POKR made some remarks, and the PRESIDENT briefly replied.

KIDDERMINSTER MEDICAL SOCIETY.—At a meeting of this Society on September 17th, Mr. D. CORNER in the chair, Mr. J. L. STRETTON read notes of a case of so-called Hermaproditism. M. F., aged 67, was born in a small village, and pronounced a female. The condition of the genitals was one of hypospadias, the under part of the urethra being absent from the orifice to the junction of the penis and scrotum, where the outlet was now situated. There had never been any sexual appetite. The person was at present an inmate of one of the female wards of the Kidderminster Workhouse by direction of the guardians and the local inspector, who still maintain that he is a woman, and the Local Government Board see no reason to interfere.—Mr. P. E. DAVIES showed the Kidneys from a case of purpura (a boy aged 5), which exhibited numerous hæmorrhages.—Mr. J. L. STRETTON related a case in which he had performed Laparotomy for Intestinal Obstruction. The patient died of collapse. On *post-mortem* examination it was found that the root of the constricting band (which had been divided) was about the diameter of the little finger; it had extended from midway above the transverse colon (attached to its mesentery), across it, binding it down, and was attached to the mesentery of the ileum near the caecum. There were several recent adhesions between the colon and the abdominal wall. The obstruction had been relieved by the operation. Treves spoke of the condition as a pathological curiosity.—Dr. EVANS showed a girl, aged 14, from whose right leg the whole of the diaphysis of the tibia had spontaneously exfoliated; it was only held in its place by a small band of granulation tissue, and was easily removed. She had made an excellent recovery and had a useful limb, new bone being formed.—Mr. J. L. STRETTON read a paper on Osteotomy, with notes of 108 operations.

NEWPORT MEDICAL SOCIETY.—The annual meeting of this Society was held at the Newport Infirmary on October 2nd; A. GARROD THOMAS, M.D., in the chair. The report for the last year showed that there had been a good average attendance of members, and that useful work had been done. Reference was made to the loss the Society had suffered by the death of its late President, Dr. B. DAVIES; and also of one of its members, Dr. A. W. LOVERIDGE. The report and statement of accounts were adopted. Dr. A. G. THOMAS was unanimously elected President for the ensuing session, and Mr. G. A. DAVIES, President-elect. Messrs. Marsh, R. E. W. BREWER, GRATH, and PATON were elected members of Committee; and Mr. W. BASSETT re-elected Honorary Secretary. A vote of condolence with the relatives of the late Dr. B. DAVIES was unanimously passed.—The PRESIDENT (Dr. A. Garrod Thomas) delivered an interesting address on Some Lessons Learnt by Mistake.—A vote of thanks to the President concluded the business.

REVIEWS.

THE DISEASES AND DEFORMITIES OF THE FÆTUS: AN Attempt towards a System of Antenatal Pathology. By J. W. BALLANTYNE, M.D., etc., Lecturer on Midwifery and Gynecology, and of Diseases of Infancy and Childhood, School of Medicine, Edinburgh. Vol. II. Congenital Diseases of the Subcutaneous Tissue and Skin. Edinburgh: Oliver and Boyd. London: Simpkin, Marshall and Co., Limited. 1895. (Royal 8vo, pp. 384. 10s. 6d.)

We cannot but admire the scientific zeal which has moved Dr. BALLANTYNE to prepare a second volume of his work. The domain of teratology has the reputation of being far from an El Dorado, nevertheless a really scientific treatise

on monsters would be profitable, since its author must gain the reputation of having written a great work. Dr. Ballantyne is acquiring that reputation. We do not wish to disparage the labours of Förster, Ahlfeld and Hurst and Piersoll, but we mean that the time has come when something more than an atlas is demanded by the student of teratology. The above-named writers have provided the necessary material, which must now be utilized. An atlas of monsters vying with each other in hideousness is certainly a satire on the uses to which art may be turned. With equal certainty it may be said that such an atlas has ceased to be of the highest scientific value.

Dr. Ballantyne expounds the relations between disease and malformation, which he rightly terms antenatal pathology. The present volume is essentially pathological. The author's subject must include three conditions: first come pure monstrosities, where the pathological element remains unknown; may be it lies in some disease of germinal layers or other primitive structures difficult to detect. Then come the mixed cases, such as acardiacs, which are truly monsters in their extraordinary deficiencies, and truly pathological through the presence of general oedema and other changes due to a diverted course of the circulation. The third class includes many cases which are hardly monsters. All show marked disease.

The disorders of which the author writes are sclerema neonatorum, foetal ichthyosis, dermatitis exfoliativa, and other rare but important pathological conditions, which are often congenital, and therefore of antenatal origin. All the author's subjects are discussed at length, and with great deliberation. As might be expected, the pathogenesis of these foetal skin diseases is very obscure. It would seem easy to attribute congenital atrophy of the subcutaneous tissue, where specific disease or malformation interfering with nutrition is absent, to wasting disease or natural leanness in the mother; but this affection does not necessarily imply that the mother is lean, and Dr. Ballantyne notes that it is a matter of frequent occurrence that a patient in the last stages of pulmonary phthisis, or *in extremis* from the incoercible vomiting of pregnancy, may yet give birth to a plump well-nourished infant. The work is full of copious references.

TEXTBOOK OF FORENSIC MEDICINE AND TOXICOLOGY. By ARTHUR P. LUFF, M.D. In two volumes. London: Longmans, Green, and Co. 1895. (Demy 8vo, pp. 776. 24s.)

AFTER an introductory chapter on the duties of the medical man in regard to giving evidence, Dr. Luff devotes the first six chapters of the first volume to questions connected with the dead body, for example, the signs of death, the period at which death has taken place, the modes of death, and the mode of conducting a *post-mortem* examination for medico-legal purposes. We note that the distinction between bruises and *post-mortem* stains has been put in tabular form, which should be useful to students.

In speaking of the causes of sudden death, Dr. Luff discusses the commonest causes of sudden death in children; but, seeing the excessive rarity of any kind of sudden death in children, we think the paragraph might well be omitted in future.

The remainder of the first volume is given up to the subject of poisons. The recognised divisions and classification of the poisons are in the main followed, and, as might be expected from his official position, Dr. Luff gives with especial care and detail the chemical analysis necessary for the detection of the different poisons, and illustrations are given of the leaves and seeds of all the more important vegetable poisons. That this section of the work is well brought up to date is evident from the fact that cocaine, sulphonal, exalgine, antifebrin, and antipyrin all come in for consideration, but curiously enough there is no mention of the use of permanganate of potash as an antidote in cases of morphine poisoning, the only omission of any importance which we have found throughout the work.

In the second volume, blood and other stains are first passed in review, and Dr. Luff then passes on to speak of wounds and mechanical injuries; and, in dealing with firearms, he points out that in wounds made with the new maga-

zine rifle, the aperture of entrance is much cleaner than in that produced with rifles of an older pattern, and that the aperture of exit with the modern weapon much more resembles the aperture of entrance with the old weapon; there is much less tearing of the tissues by the modern bullet and so there is much less sloughing. The introduction of the smokeless powder, too, does away with the blackening of the wound and its edges in the case of a weapon discharged close to the body.

Deaths from asphyxia are next considered, and here we note that in the table of the appearances in the bodies of the drowned, he omits to say whether the averages given are for winter or summer. The account of pregnancy, delivery, and abortion is good and concise, and, under the heading of infanticide, special directions are given for making a *post-mortem* examination in a suspected case. Altogether we have no doubt that the work will meet with the approval of medical students, to whom it is mainly addressed. The arrangement is good and the descriptions are clear, and though there are many excellent works already in the field on the subject, we have no doubt it will take a very high place.

LES SANATORIA: TRAITEMENT ET PROPHYLAXIE DE LA PHTHISIE PULMONAIRE (Sanatoria: The Treatment and Prevention of Pulmonary Phthisis). Par le Dr. S. A. KNOPF. Paris: George Carré. 1895. (Large 8vo, pp. 206. Fr. 6.)

THIS volume, a thesis presented for the degree of M.D. to the Paris Faculty by an American physician, is possessed of rather more general interest than usually belongs to such academic exercises. It is written in a tone of conventional deference which contrasts in a rather amusing way with the independent views and settled opinions which the author obviously entertains.

After a brief historical sketch and some observations on the pathological and clinical evidences of the curability of tuberculous disease of lungs, Dr. Knopf describes a number of sanatoria which he has visited, and gives a list of others in Europe and America. The descriptions are in some instances illustrated by photographs, and form a most interesting part of the essay, though as a rule too brief. The author would have added much to the practical value of his book not only by entering into greater detail in his account of the plan and management of the institutions themselves, but also by appending notes as to travelling and as to the cost of living. The majority of the institutions described are in German-speaking countries—Falkenstein, the three institutions at Goerbersdorf, Hohenhonnef, Reiboldsgrün, St. Blasien in the Black Forest, and Davos. Brief descriptions are also given of the sanatoria at Canigon (Pyrenees), Leysin (Switzerland), the Ventnor Hospital, Craigleith, and the Adirondack Cottage Sanitarium, New York. We do not notice any mention of Bournemouth.

Almost the only point which the sanatoria for phthisis have in common is that all are built in pure air, and that the patients spend a great deal of time in the open air, and that they are required to submit absolutely to the benign autocracy by which each is governed. One of the aphorisms inscribed on the walls of Brehmer's sanatorium at Goerbersdorf might be the motto of all these institutions: "The best occupation for a sick person is to labour to become well," and it is therefore not surprising to read that Dr. Knopf, during his visit to Leysin, was "very disagreeably surprised to see that a *kursaal* (caldé casino) was in course of construction not far from the sanatorium." Dr. Knopf next describes, with plans drawn by Mr. Van Pelt, architect, an "ideal sanatorium," though we are left in doubt as to whether the ideal is ever to become the actual. Dr. Knopf insists with justice on the essential importance of the strict medical supervision exercised in the best sanatoria. The number of hours to be spent in the open air, the quantity and quality of the food, the amount and character of the exercise to be taken are all determined by the medical officers, who apply general principles after a careful study of the individual cases. Pure air, and such a sheltered sunny situation that the patients may be in the open air either on foot in the woods and grounds, or resting in reclining chairs in shady verandahs for many hours a day, are the two main points to be sought in choosing a site.

Dr. Knopf urges the erection of such sanatoria for patients of the poorer classes, who are able to pay little or nothing towards their maintenance; and he enters into an elaborate calculation to prove that for the city of Paris this system would be little more costly, if at all, than the present want of system by which phthisical patients are again and again treated for short periods in the general hospitals. He assumes, it is to be feared correctly, that all of these patients succumb after a few months or years of incapacity; he asserts that the statistics of German sanatoria prove that of early cases 14 per cent. recover completely, 14 per cent. are "relatively" cured, and 42 per cent. are improved.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

CONDENSED SWISS MILK AND CONDENSED UNSWEETENED NORWEGIAN MILK.

IN view of the recent inquiry instituted by the *BRITISH MEDICAL JOURNAL* with respect to milk and condensed milk, we have been requested by Mr. H. Nestlé, of Vevey, Switzerland, to analyse a sample of "Nestlé's Condensed Swiss Milk," and by Messrs. Anderson and Colman, of 5, Philpot Lane, E.C., to analyse the "Viking Condensed Unsweetened Milk," prepared by the Norwegian Milk Condensing Company, of Christiania, Norway.

The results of our analysis of Nestlé's Swiss milk show that it has the composition of a genuine sweetened condensed milk of very good quality. The sample examined by us contained 10.23 per cent. by weight of milk fat and the other constituents were present in proper proportion to the fat.

Our analysis of the condensed unsweetened Norwegian milk shows that it has the composition of an unsweetened condensed milk of very good quality, obtained by condensing genuine cow's milk. The sample examined by us contained 34.5 per cent. of total solid matters. The percentage of milk fat was 10.27. When mixed with about 2½ parts of water a liquid closely resembling ordinary genuine fresh milk of good quality is obtained, and it is to be noted that a condensed milk of this kind differs from the ordinary types of condensed milk in that it contains no added sugars. The preservation of the milk in the tins has been effected without the addition of objectionable chemicals.

Having regard to the revelations we have made as to the characters of so many of the preparations which are bought by the public as condensed milk, it is satisfactory to be able to call attention to high class products such as these here referred to.

PARAFFIN SAFETY LAMPS.

Messrs. KIRKON AND Co. (25, Fore Street Avenue, E.C.) have submitted to us a safety lamp for use with paraffin oil, which contains a novel feature in the formation of the wick tube. This, which descends nearly to the bottom of the oil vessel, although not so nearly as we think it is well that it should do, is bent into an S-shaped curve in such a way as to form a "trap" which will become filled with oil in whichever direction the lamp may happen to fall, the intention being to prevent all possibility of access of the flame to the gases in the partially empty oil vessel. The intention is good, and it is probable that the arrangement might lessen the risk of explosion when the oil in the reservoir is so low that the lower end of the wick tube is uncovered when the lamp is overturned. Whenever there is sufficient oil to cover the bottom of the tube, as in the diagram accompanying the specimen forwarded to us, there seems to be no special advantage in the S-shaped curve. It is curious that an inventor who so far recognises the principles of construction as to make his lamp of metal, and to carry his wick in a metal tube to the bottom of the oil chamber, all for the sake of preventing his lamp from exploding if it should chance to be upset, should

at the same time construct his lamp with so narrow a base as to make it almost certain that it will be overturned. But it is still more curious that, after taking all the trouble not only to put in a wick tube, but to make it of a special shape for trapping off the gases in the oil chamber, he should make two little holes at the very top of the wick tube through which any down-flashing flame would obtain direct access to the vapour from which the tube is intended to cut it off. This is, indeed, swallowing a camel while straining at a gnat. The existence of these holes would appear to neutralise the benefit derived from the arrangement of the wick tube, and thus the chief advantage of the lamp would seem to lie in its being made of metal.

THE FIFTH INTERNATIONAL CONGRESS OF OTOLOGY.

[FROM OUR SPECIAL CORRESPONDENT.]

SINCE the first of these gatherings was held in America, in 1876, successive meetings have taken place in Milan, Basle, and Brussels. The fifth was held last week in Florence, and proved in every way to be a most decided success, under the presidency of Professor Vittorio Grazzi. The choice of an Italian city for the second time within the relatively short space of twenty years shows the general sympathy for the country, and the affection with which Italy is regarded was shown at the Congress by the applause which greeted Dr. St. Clair Thomson when he spoke of the feeling of fraternity and of freedom in meeting on the common soil of the mother of nations.

The autumn crop of congresses has been particularly abundant in Italy this year, including those of Geology, History, Accountants, Garibaldian Veterans, Co-operations of Manufacture and Labour, Internal Medicine, and of Barbers! The latter have shown their solidarity by deciding to close on holidays, to keep the First of May as a labour *fête* day, and to appoint as their organ *La Voce del Parrucchiere*.

This profusion of congresses and the time of the year may account for the absence of any high dignitaries of State or City at the opening ceremony on September 23rd. They all, however, were most courteous in the messages sent, while they showed their practical hospitality by throwing open without fee, not only the art treasures of the Tuscan capital, but also the gardens and private apartments of the royal palaces and villas. The hospitalities of the municipality were most highly appreciated.

An afternoon reception was given at the Palazzo Vecchio, when visitors were received in the wing called after Leo X. by Councillor Picchi (representing the Prefect), Alderman Chevalier Artimini (representing the Syndic), General Driquet, Chevalier Hermite, and others, representing the army, the law, etc. In addition to more substantial delights, flowers were liberally presented to the ladies of the party, and the *congressisti*, after visiting the historic hall of the Cinque Cento and the apartments of Eleonora of Toledo, ascended the tower to see the prison of Savonarola and enjoy the magnificent view over the City of Flowers and the valley of the Arno. Another civic hospitality was an excursion to the old Etruscan city of Fiesole. Private bodies were well represented by the charming concert given in the Palazzo Fucci by the Artists' Club. Here visitors had an opportunity of seeing some modern Italian pictures, and of enjoying some most delightful amateur music. Finally, the colleagues of the speciality throughout Italy united with the profession and the citizens of Florence in giving a banquet, which was most completely successful. As for the President, Dr. Grazzi, and his charming wife, their hospitality was simply unending throughout the week. Not only did they initiate it with a ball, and continue with a succession of luncheons and dinners, but the size of their magnificent apartment allowed them to give a dinner to over eighty of the foreign visitors. Nor must we neglect the share taken by the Anglo-American doctors resident in Florence for the entertainment of their compatriots. The Florence Club was, through their intervention, thrown open to visitors, and proved to be a welcome gathering point; while Drs. Coldstream and Baldwin offered both hospitality and help, which was greatly appreciated by visitors from Great Britain and the States.

Taken as a whole, the scientific work of the Congress showed the general and steady progress of otology; there was nothing particularly striking in the way of originality; several papers were of great pathological and clinical interest, and in certain points there appeared the commencement of a wise conservative reaction from some recent operative proceedings.

Four general subjects were discussed. General Treatment in Diseases of the Ear was sketched by Dr. Gellé (Paris), and General Treatment in Diseases of the Internal Ear, by Professor Gradenigo (Turin). The question of the Treatment of Intracranial Abscesses consequent on Purulent Disease of the Ear lost some of its interest through the unavoidable absence through illness, of its introducer, Dr. Thomas Barr (Glasgow); his article was read by Dr. Urban Pritchard, who elucidated it by his own valuable experience, and his conclusions were placed under the headings of questions which were submitted to the Congress: (1) Should these cases be in the hands of the aurist or the general surgeon? (2) Should the cranium be opened in cases of meningitis without definite indications of localised abscess? (3) How should the sinuses be treated? (4) What is the best method of opening the skull? Needless to say that in such a Congress the opinion was unanimous in favour of such cases being in the hands of aurists. Our Present Knowledge of the Pathological Anatomy of the Labyrinth called forth a scholarly and scientific paper from Professor Politzer, which was illustrated by a beautiful collection of specimens.

The fourth subject, the Physiology of the Middle Ear, was introduced by Dr. Carlo Secchi, of Milan.

A large number of communications were read and discussed. We have only space to refer to those of representatives of the United Kingdom. Dr. Macnaughton Jones read a paper on the Relation of Turbinal Hypertrophy to Deafness, with special reference to the operation of turbinotomy. With regard to the association of this affection and deafness or tinnitus, he quoted Loewenberg, Solis Cohen, Hartmann, St. John Roosa, Spalding, Swanzy, Wolf, Berthold, and Guye, all of whom gave a more or less negative reply in some cases modified in consequence of the coincidence of nasopharyngeal catarrh. An equally positive reply was given by Turnbull, Barnett, Bosworth, and Lefferts. The author's own conclusions were: 1. That turbinal hypertrophy should be regarded as a serious complication of deafness and allied aural troubles; when it precedes the aural symptoms it can with justice be regarded as the principal cause. 2. When detected it should be treated by active therapeutic measures, of which the principal is the galvano-cautery. 3. Deviation and spurs of the septum are rarely, perhaps never, the cause of deafness and only become so in those cases which are complicated with turbinal hypertrophy. 4. If in any case it is found that the occlusion of one nostril is partly due to a septal deviation or spur this should be corrected. 5. Turbinotomy should be reserved for those cases where it is useless to hope for an amelioration from any other treatment; this occurs in a relatively small number of aural cases.

Dr. A. Bronner (Bradford) read a practical paper on Local Massage in the Treatment of Chronic Eczema of the External Meatus. Dr. St. Clair Thomson discussed the question of Antiseptics in Nasal Surgery and of Intranasal Medication. Mr. Cresswell Baber demonstrated his models and dummy for examining the nose, and Dr. Macnaughton Jones showed several instruments. Dr. Urban Pritchard and Dr. Dundas Grant took part in several of the debates.

It was unanimously agreed to hold the sixth congress in London in 1899, and a British Committee was appointed to carry out all the business and local arrangements.

DEATHS UNDER ANÆSTHETICS.

CHLOROFORM.

MR. RICHARD COATES, House-Surgeon at the Newport Infirmary, has favoured us with the following account of death under chloroform, which occurred recently at that infirmary:

The patient, a man 47 years of age, had been under treatment in the casualty department of the Newport Infirmary for six weeks, suffering from a man-bite of the index finger of the right hand. The wound had been neglected, and when

the patient came to the out-patient department an operation was performed under chloroform, and the first, second, and third phalanges of the index finger were removed, the patient taking the chloroform very well. The wound suppurated, and numerous incisions had to be made into the palm of the hand to let out the pus, which collected in large quantities despite the insertion of drainage tubes. The inflammation at last settled down, and on probing a sinus dead bone was discovered in the base of the second metacarpal bone. As the man was not well enough to have the operation performed while still an out-patient, he was advised to become an in-patient, and was admitted on September 21st, six weeks after the primary operation. He remained inside until September 24th, and during that time his general health improved. A routine examination of the patient was made. The cardiac dulness was normal; the heart's action was regular but feeble, there was no evidence of valvular disease or degeneration, no albumen in the urine, and the lungs were normal. He was considered a fit case for anaesthesia, and was prepared in the usual way for the operation. On the morning of the operation he was extremely nervous, and dreaded the anæsthetic very much, but was anxious to get the operation over. Chloroform was administered from a graduated drop bottle, and was given in drops poured continuously on one layer of a smooth towel folded in the shape of a cone. The patient took the chloroform well, but when nearly under he struggled a little, ten minutes after the commencement, and had a tonic spasm which took the form of opisthotonos; the spasm lasted half a minute, during which time no air entered the chest. The patient was restrained only so much as to prevent him from falling from the table. He became relaxed, and the chloroform was cautiously continued. He breathed quietly for a minute, the corneal reflex was gone, and the patient looked well in every way. The surgeon commenced to unfasten the bandage, when the patient suddenly became pale and then livid. A gag was immediately placed in the mouth, the tongue drawn forward, the head depressed, artificial respiration commenced, and a capsule of nitrite of amyl broken over the mouth and nose. Air entered the lungs freely, but the heart had stopped; the pupils were neither contracted nor dilated. Twenty minims of ether were injected subcutaneously over the præcordium, the electric battery was applied, an enema of brandy given, the skin stimulated by scrubbing, and the chest ficked with a towel wrung out in cold water. Artificial respiration was kept up for three-quarters of an hour, and air entered the chest freely the whole time, but the heart never beat after the first stoppage. A post-mortem examination was made on a coroner's order, forty-eight hours after death. The heart weighed 18½ ounces, and was slightly enlarged; the pericardium had an excess of fat on it; the organ was empty and flabby; the walls of the ventricles were thinner than normal, especially the right, in which there was a small coagulum; the valves were healthy, the arteries normal, the lungs were slightly emphysematous, and all the other organs were healthy. Death was undoubtedly due to primary heart failure. About 3½ of chloroform (Duncan and Flockhart's) were used.

SCIENTIFIC TEACHING AS TO ALCOHOL.

At the National Temperance Congress held at Chester, Dr. W. Carter (Liverpool) discussed the Practical Benefits of Abstinence from a Physician's Point of View. Three broad principal facts, he said, had been firmly established: (1) Those people who entirely abstained from alcohol lived longer than those who used it even moderately; (2) the abstainer worked harder and longer than the moderate drinker; and (3) intellectual energy could be well sustained, and was as great without as with alcohol. In a paper on Alcohol as a Narcotic, Dr. McDowell Congrave, Professor of Biology at the Royal College of Surgeons in Ireland, stated that during the past few years a number of observers had tested the effect of small doses of alcohol upon the special senses, and had all come to the conclusion that from the very first alcohol acted upon the body as a narcotic and not as a stimulant. The same thing had been found true of the action of alcohol upon the mind. It caused mental processes to be slower but gave

the idea that they were really faster. This explained how it was that people often continued to use alcohol when those around them saw that it was doing them harm. A paper, entitled *Alcohol, the Antagonist of Hygiene*, was read by Dr. Vacher, Medical Officer of Health for Cheshire, who said that the effect of alcohol on the living growing body, as had been shown experimentally, was to make growth less perfect and the system less able to resist the forces that made for decay. He then passed on to consider the question whether alcoholic liquors and the facility given for obtaining them co-operated with the sanitary authority or thwarted its best efforts; and it was shown that alcohol was the opponent of hygiene. Dr. F. H. Walsley, Medical Superintendent of the Metropolitan District Idiot Asylum, stated that pauper lunatics in London were increasing at the rate of 500 a-year. It was now universally admitted that alcohol was directly or indirectly responsible for more mental and physical incapacity and suffering than any other single known cause of disease. Out of 11 cases of those who became insane, 9 ultimately died insane, and of the remaining 2 but 1 entirely recovered. The lunacy laws filled a big octavo volume, yet one clause forbidding the marriage of those in whom the taint existed, and another to prevent people driving themselves mad with drink would be worth the whole volume. Dr. Annie McCall, Director of the Clapham Maternity Hospital, suggested that all police should be total abstainers. Dr. Crespi, of Wimbourne, complained of the amount of ignorance which still prevailed amongst medical men on the temperance question; and Mr. W. S. Caine said that one of the great difficulties was the indiscriminate and ignorant manner in which large sections of the medical profession prescribed alcohol. Mrs. H. Kingsley complained of the way in which country doctors ordered alcohol; and Mr. Garrard, of Hackney, of the way in which Band of Hope members had broken their pledges owing to medical advice and sickness. Dr. William Flint said that the difficulty of country practitioners was that patients were eager to take stimulants, and that if one doctor would not prescribe them they would call in another who would.

THE DOCTRINE OF THE TEA-KETTLE AND THE PASTEUR FILTER IN INDIA.

SINCE Mr. Ernest Hart's visit to India and the crusade of the policy of the tea-kettle immediately upon the occurrence of any outbreak of typhoid, cholera, dysentery, or malaria, notices such as the following are, we are glad to see, constantly appearing in the Indian papers:

The epidemic of dysentery which has recently proved so fatal in the Sussex Regiment, stationed at Dum-Dum, has now almost entirely disappeared. It is significant to notice the fact that its disappearance has been synchronous with the abolition of the filters previously in use by the men, and the introduction instead of a system of boiling the whole of their drinking water.—*Indian Daily News*.

A well-informed correspondent at headquarters in India, who forwards this to us writes: "The subject of the best methods of combating typhoid, cholera, dysentery, and malaria are engaging more actively than ever the attention of the medical authorities in charge of the military stations and of the Government generally. The proofs which have now been adduced of the absolute inefficiency and even increase of danger arising from the use of the Macnamara filters—which Mr. Hart denounced in his address at the Calcutta Congress as the worst in the world—have slowly but surely wrought upon the convictions of our sanitary and civil authorities here, and I believe also of the military authorities both of the Indian army and the British forces. In the gaols, too, the matter is being seriously considered. Numerous circulars have been issued in Bengal, I hear, to the gaol authorities, calling their attention to the subject of the Pasteur filters, which have proved themselves the only thoroughly efficient means of filtration for the purpose of excluding infectious germs, which are coming more and more into favour, and will no doubt in time be officially introduced into all public establishments. The policy of the tea-kettle also, which Mr. Hart so picturesquely illustrated, is being put to an official but rather daring test by Sir Anthony MacDonnell, who was at the time of Mr. Hart's visit here the active and accomplished Secretary of the Home Department, and who received a deputation, of

which he was spokesman, from the Congress, urging its adoption of increasing methods and facilities for bacteriological research and the adoption of an active policy for purifying the water supply of the gaols, prisons, hospitals, and other establishments, and in the villages of the native population. Sir Anthony MacDonnell, who is now Lieutenant-Governor of the North-West Provinces, has issued an order directing that half of the inmates of the gaols of that province should be supplied with boiled water, and the other half receive still the existing water supply. In England such an order might be resented by public opinion of a sentimental kind, as being in the nature of an experiment on human lives, for if it be true, as Mr. Hart declared, that the supply of either efficiently boiled or perfectly filtered water would annihilate epidemics of typhoid and cholera, and would largely diminish dysentery and malaria within the gaols, there seems no reason why the order in question should not apply to the whole of the inmates. The results, though less scientifically rigid from the scientific experimental point of view, might be not less satisfactorily worked out by comparing the mortality from these diseases subsequent to the issue of the order to that of the years preceding it, other conditions being the same. However that may be, it might be well if the Governor of the Punjab should order that one half of the prisoners should be supplied with efficiently boiled water, and the other half with water passed through the germ-proof filters of Pasteur. This would have the effect of trying two measures of protection of health and life, both of them possibly thoroughly efficient. There is no doubt that boiled water will prove to be a most efficient protection against many enteric diseases and malarial poisons, but it is, unless subsequent oxygenation is resorted to, a very tasteless fluid, and one to which many object, while the same objection does not apply to water efficiently filtered by germ-proof filters, which, as a permanent measure, is of course more economical and in many ways likely to prove more acceptable. The outbreak of enteric fever at Poonah and the very large number of deaths from typhoid and enteric fever in the Chitral expedition, where the soldiers drank water which was neither boiled nor filtered, are attracting much public attention, and no doubt medical officers and regimental officers in command will in future be much more alive to the necessity of meeting public opinion by taking the measures which Mr. Hart so urgently recommended than they have been hitherto. The recent experience at Bangalore and at Dum-Dum yet have, as they probably will be, to be properly emphasised by medical opinion, and may by the aid of the press here prove both instructive and life-saving. It is useless and unnecessary to inflict blame in these cases for the preventable loss of valuable lives which have occurred, for they are only examples of what is still going on all over India, and until public opinion was thoroughly aroused by Mr. Hart's address at Calcutta comparatively little attention was given to the subject, although what he had to say in the matter was of course not either absolutely new or altogether unheeded. The doctrine of the tea-kettle and the germ-proof filter has now, thanks to his picturesque and energetic advocacy, definitely made its appearance on the stage of Indian sanitation; and it has come there to stop. Although I am one of those who must take my share of blame for not having as earnestly preached and acted on the truth of the doctrine which was in me, I am nevertheless one of the first to recognise the vast importance of the universal application of this knowledge; and I think we may be all well content, putting aside all questions of blame in the past, to press forward the universal application in the present and in the future of what it is now evident is likely to become a new and life-saving matter of doctrinal practice in this vast Empire."

In New York recently several milk sellers, convicted at the instance of the health authorities of adulteration, have not only been fined but imprisoned. It is stated that as a result the sale of adulterated milk has almost ceased.

Das Zeitschrift für Physiologische Chemie, founded by the late Professor Hoppe-Seyler, and edited by him for many years, will in future be edited by Professors Baumann, of Freiburg, and Kossel, of Marburg, who have been for some time associated with him in the task of editing.

LITERARY NOTES.

MESSERS. BAILLIÈRE TINDALL, AND COX announce the publication of an unusual number of new works and new editions during the coming season. On October 1st they issued an original work on *Physiology* by Professor Stewart, of the Cambridge University Museum, lately Examiner in Physiology at Aberdeen University, now Professor of Physiology in the Western University, Cleveland. They will also publish a translation of Professor Kaposi's classical *Diseases of the Skin*, and a translation by Dr. Ernest Clarke of Professor Haab's *Atlas of Ophthalmoscopy*, with 64 coloured plates; new works by Dr. Sachs on *The Nervous Diseases of Children*, by Professor Max Knies on *The Relations of the Eye to Diseases of the Body*, by Dr. John Broadbent on *Adherent Pericardium*, and a new edition of Peddie's *Physics*.

In a recent number of the *Century* Dr. Max Nordau, in replying to his critics, gives some interesting information about himself. Since the publication of his work *Degeneration* he has so frequently been said to be himself a degenerate and a lunatic, and to be descended from insane ancestors, that he thinks it worth while to state that the only evidence of an abnormal mental condition which has ever been observed in the members of his family is a strange indifference to money. He adds:

For several generations both my paternal and my maternal ancestors have accordingly been poor. They did not understand how to make money. They did not concern themselves about it. They preferred to occupy themselves with abstruse scholarship. They were rabbis or officials of Jewish congregations. As their heir I have had frequent occasion to reproach them with their lack of worldly sense, but as an atheist I should hesitate, on account of this defect, to charge them with insanity.

To the objection that in dealing with such a subject as degeneration he had violated the precept *ne sutor crepidam*, he answers that although he is neither an expert in psychiatry nor the director of a lunatic asylum, he for eight years attended the clinical lectures of the late Professor Ball, and accompanied him on his visits to the St. Anne Asylum, Paris; he therefore resents the imputation that he is a mere dilettante in the matter of mental pathology. He denies that his teaching implies that all genius is a form of degeneration. It is by no means a rare thing, he says, for men of true genius to suffer from mental disease. But that is far from proving that true genius is in its essence degenerate. It is as absurd to say that all genius is a form of degeneration as it would be to maintain that, because many athletes suffer from hypertrophy and fatty degeneration of the cardiac heart, athleticism is a form of heart disease. Genius is incidental to evolution; degeneration, on the other hand, is retrogressive—a form of atavism which, if it were to become general, would cause the species to revert to stages of development long since past. As there has been a good deal of uncertainty about the distinguished author's patronymic, the following extract from a letter written by him to the *Jewish Chronicle* may be of interest:

You go on saying "Max Nordau's real name is Simon Südfeld." This is a falsehood which you might have avoided with the slightest measure of care. My petty names (or ought I to say my "Christian names"?) are Max Simon. After having assumed, at my father's behest, for reasons that have no interest for strangers, and at the age of 15, the name of Nordau, I had this name officially and legally conferred upon me by decree of Karl von Zoyk, then Royal Hungarian Minister of the Interior, under number 12,138, and the date of April 11th, 1873. Since then, Nordau is my "real" name, and I have no legal right to bear and use another.

Messrs. MacLehose and Sons will publish a new edition of Dr. Barr's *Manual of Diseases of the Ear; Deaf-Mutism*, a treatise on diseases of the ear, as shown in deaf-mutes, with chapters on the education and training of deaf-mutes, by James Kerr Love, M.D., and W. H. Addison; and *An Account of the Institution and Progress of the Faculty of Physicians and Surgeons of Glasgow*, by Alexander Duncan, Secretary and Librarian to the Faculty.

The *Library* complains that in some libraries the current numbers of medical journals are placed in the reading room, thus bringing them within the easy reach of the youth of both sexes. We quite agree with our contemporary that if such journals are taken at all, they should be kept under the strict care of the librarian or some responsible officer, and given out only to adults.

Messrs. Longmans and Co. have just published Fr.

Elizabeth Blackwell's *Pioneer Work in Opening the Medical Profession to Women*; it consists of autobiographical sketches. The same firm will also publish *A Book for Every Woman: Being Suggestions as to the Management of Health from Childhood to Old Age*, by Jane H. Walker, out-patient physician to the New Hospital for Women.

Dr. Bayard Holmes, of Chicago, has taken up the question of the "Medical Library of the Medical School of the Small Community." He holds that changes are necessary in the teaching of medicine corresponding to that which has come about in histology. Lectures alone, he thinks, are no longer adequate; there should be the same possibility of studying the literature of a medical case as there is now of studying in the laboratory the development of the eye. Hence the necessity for a well-arranged working library in each medical school. The objects to be aimed at in the formation of a medical college library are, according to Dr. Bayard Holmes, the following: 1. To furnish the means of training students in medical bibliography and bibliographical research. 2. To furnish, through its medical literature, material for the study of each and every medical science which now forms a part of the medical curriculum. 3. To furnish material for the study of the sciences collateral to medicine. 4. To make possible the proper pedagogic methods in medical schools. Incidentally some interesting information is given as to public libraries in America. In 1891 there were 3,503 public libraries in the United States, containing 28,826,000 bound volumes and 4,340,000 pamphlets, or 31,167,000 books in all, making an average of 8,194 volumes in each library, or about 50 books to each 100 of the population. At the same time there were 59 public medical libraries in the States, only 6 of which contained more than 10,000 volumes. These were the library of the Surgeon-General's office in Washington, with 104,000 volumes; that of the College of Physicians in Philadelphia, with 41,000 volumes; that of the Pennsylvania Hospital, with 14,000 volumes; that of the New York Academy of Medicine, with 30,000 volumes; that of the New York Hospital, with 20,000 volumes; and the Boston Medical Library Association, with 21,555 volumes. Mention is not made in this report of the Newberry Library, in Chicago, which has about 25,000 volumes in its medical department. On comparing the department libraries of the various universities having medical departments and departments of law and theology with each other, it is found that Harvard Medical School, with 300 students, has only 1,500 volumes in its library, while the general university library has 292,000 volumes; the law department, with 366 students, has 28,167 volumes, and the theological school, with 85 students, has 23,360 volumes. The same inequality exists at Yale College, with its 1,755 students, where there are 185,000 volumes in the library. The medical school, with 72 medical students, has 3,000 volumes in its library. Again, there are many cities with 20,000 or more inhabitants, with flourishing medical societies, but no library worthy of mention. A number of medical societies, especially in the eastern States, report as high as 6,000 or 8,000 volumes in their libraries, but these libraries are in no sense working libraries, being old libraries and without adequate catalogues.

The *Parish Register of Skipton-in-Craven*, vol. 2, 1680-1771, edited by the Rector of Burnsall, contains some notice of small-pox epidemics in 1716 and subsequent years, besides many entries relating to families connected with the neighbourhood. Application for the volume should be made to the Rev. W. J. Stavert, Rector of Burnsall.

The following are among the scientific announcements of the Cambridge University Press for the autumn: *Textbook of Physical Anthropology*, by Professor Macalister; and a second edition of *Practical Physiology of Plants*, by F. Darwin and E. H. Acton.

The first volume of the *Transactions of the Eighth International Congress of Hygiene and Demography*, held at Buda-Pesth in 1894, is ready for delivery to members of the Congress. Members who have changed their place of residence or who omitted to give their address to the Secretary at the time of the Congress should communicate with Dr. Sigismund von Gerlőczy, Rochusspital, Buda-Pesth. Persons not members can obtain the volume on application to the Director of the Rochusspital with enclosure of 12 florins (Austrian), being 10 for the book and 2 for postage.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription accounts close on October 31st, and all unpaid subscriptions must be forwarded after that date to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, OCTOBER 12TH, 1895.

A LAY SERMON.

SIR EDWIN ARNOLD is not the first poet who has seen the poetical side of hospital life. There is that strange and beautiful scene in *Love's Labour Lost*, where Rosaline sends her idle lover to test his wits for a year in a hospital, and see how small he will feel in the presence of the life within its walls. And there are Henley's wonderful lyrical poems *In a Hospital*, his own experience in Edinburgh Infirmary, with such an account of his taking chloroform as few poets could have written. And there is the account of the little hospital in *The Ring and the Book*, where Pompilia found rest at last. The poets have always known how to value our work, from Homer, who said that a physician was worth many other men, down to Robert Louis Stevenson. "The physician," says Stevenson, "is the flower of our civilisation. Generosity he has, such as is possible to those who practise an art, never to those who drive a trade; discretion, tested by a hundred secrets; tact, tried in a thousand embarrassments; and what are more important, Heracleian cheerfulness and courage."

Sir Edwin Arnold could thus join the company of the doctors without leaving that of the poets. His praise of our calling is admirable, and it is not all praise that is worth hearing or having—the after-dinner compliments, when somebody proposes "The Staff," and the excessive gratitude of patients who dare not be ill or do not care to be well, and the glowing descriptions in novels of heroic doctors who cure and marry the heroines—none of these praises are of much value; but in this wise and eloquent address to the students at St. Thomas's Hospital, Sir Edwin Arnold paid the tribute to our work that we deserve and desire to receive; and he has given pleasure not only to those who heard him, but to all who now read what he said.

Three lines of thought converge in his address toward his estimate of our profession: and they are just those that we should expect in the one Englishman who is at once a poet and an exponent of the faith of the East. First, in the advance of our art, what most appeals to him is the discovery of anesthetics. Next, among the methods by which that advance has been made, that alone concerns him which involves experiment on animals. Last, among the influences of hospital life on hospital students, he is most concerned with the growth or loss of the student's faith. Following Sir Edwin Arnold along these lines of thought, let

us see how far we in our profession agree with what he, as a layman, has said so well.

As regards the discovery of anesthetics, the story was told some years ago by Sir James Paget in the *Nineteenth Century*, and by Sir Russell Reynolds at a University College Hospital dinner in 1888. It is strange that of the three men who made the discovery in America not one attained success in later life; indeed, one became bankrupt, and one died by his own hand. It is strange, too, that in our own country the use of chloroform to relieve the pains of labour was met at first by a storm of opposition from all sorts and conditions of men, including many of our own profession. The attitude of one surgeon toward the great discovery is best told in Sir Russell Reynolds's own words: "The first operation in this country performed under an anesthetic was witnessed in University College Hospital. Liston had consented to try the anesthetic. I can see him now as he said to the students, 'Gentlemen, we are going to try a Yankee dodge for making men insensible.'.....At length Peter Squire said, 'He is quite ready now, sir.' Liston's knife flashed in the air; I took out my watch to count the time, and the leg was on the floor in six-and-twenty seconds. Liston turned to the students and said, 'This Yankee dodge, gentlemen, beats mesmerism hollow.'" That was all the welcome given to the first use of anesthetics in England. There was no public rejoicing, no Thanksgiving Day, no Te Deum in the churches, no commemoration of the discoverers; the great discovery had to make its way against obstinate prejudice and folly in high places, even in some of our profession; and Liston's somewhat grudging utterance should serve as a warning to those of us who make light of new methods only because they are new. We are glad that Sir Edwin Arnold saw only the discovery itself, and not the way in which it was received.

Next, as regards experiments on animals, we agree with him that these should be as few as possible; that every possible precaution should be taken to avoid the inflicting of pain; and that the use of such experiments should be allowed to those alone who are thoroughly qualified to make them. The Act of Parliament which enforces all these limitations, and others in addition to these, should be carefully studied by every person who wishes to know the truth as to experiments on animals in this country. And with the Act he should also study the Inspector's annual reports, and observe that a very large proportion of these experiments are simple inoculations, and that in every experiment, where the initial operation is of such a nature as to cause pain, this must be done under an anesthetic.

Anyone who will read these reports will see that the sum of pain is indeed small when it is compared with such discoveries as the localisation of the centres of the cortex, the treatment of myxœdema with thyroid extract, or the preparation of the antitoxins. We agree also with Sir Edwin Arnold that any experiment on animals should be made with a grave sense of responsibility, and, as it were, under compulsion; we believe that in England this is the spirit in which they are made. Students, of course, do not make them. We are glad that Sir Edwin has spoken on this subject with better judgment than the two great poets of our age, Tennyson and Browning.

Finally, as regards his belief that the experiences of a hospital life are such as to strengthen the faith of its

students, he must remember that when a student begins his work his mind is either set one way or the other, or is still halting between two opinions. He whose mind is already fixed, either *pro* or *con.*, will probably during his student days still go whither the earlier influences of home, school, or university have led him. He who has "not made up his mind" will probably, as a student, turn toward negation: but in after years he will see many things that are now hid from him. At any rate, the old aggressive sort of young iconoclast is passing away; the joke of not finding the soul while dissecting the brain is happily played out; the student sets himself to his work, and keeps his thoughts on these things to himself, till time shall set them in their proper order and significance.

FACTORY SURGEONS AND THEIR FUNCTIONS.

A NEW departure was taken by Dr. A. P. Laurie in the introductory address at St. Mary's Hospital, published in the *BRITISH MEDICAL JOURNAL* of October 5th. His main point was to demonstrate the need for a closer connection between medicine and the administration of the factory laws. This want has long been clear to every reflecting and observant mind. As long since asserted by Lord Cross when he occupied the post of Home Secretary, factory laws are sanitary measures designed to secure the health and welfare of factory operatives. This fact has not sufficiently arrested the attention of the profession in the numerous discussions and propositions that have taken place in regard to sanitary science. Moreover, as Dr. Laurie states, the medical men engaged in the service of the factory office have, as a rule, not availed themselves of their position and opportunities to study and bring to notice the relations subsisting between health and employment, or to investigate diseases incident to occupation, and he points out various unsolved problems the solution of which calls for the direct aid of medical experts.

In the midst of the inactivity and indifference deplored, it is highly pleasing to welcome Dr. Laurie as a recruit to the small band of those who desire to give a due place to medical knowledge and experience in industrial hygiene, and who claim for the profession its rightful position in questions concerning the sanitary aspects of occupation and the means requisite to secure to the working classes those plans most conducive to their health.

Excepting those who have specially examined the matter, none can realise how much suffering and death are bound up with manufacturing operations, nor to how great extent those evils are remediable.

Dr. Laurie adverted to the special investigations promoted by the late Home Secretary, Mr. Asquith, which have cleared up many points connected with the effects of employment on health and life—sufficient surely to arouse public attention, though insufficient to suggest remedies for the evils revealed. They need to be considerably supplemented by additional inquiries, whilst the results of remedial measures hitherto attempted call for examination and report, so that the direction in which new attempts shall be made may be rendered obvious.

In fact, finality in this matter of investigation is remote, if indeed, ever attainable. New manufactures are ever opening up, and in old-established ones novel processes are

perpetually introduced. The consequence is that new industrial evils constantly arise, and the preventive means calculated on as sufficient in past times are thrust aside as useless, or no longer efficient.

These considerations indicate the necessity of some standing authority competent to advise what alterations of special provisions need be enforced by legislation. In what direction, Dr. Laurie inquires, are we to look for a basis on which such an authority may be founded? This he finds in a reorganisation of the staff of certifying surgeons appointed by the Chief Inspector of Factories, with the sanction of the Home Secretary. In this body he recognises the first factors in any scheme for the constitution of a consultative committee to determine what special provisions and rules are to be enforced for depriving manufacturing processes of their terrors to health, to limb, and to life.

All this implies activity on the part of certifying surgeons in observing and recording the effects on health of all occupations under their notice, and also the results of all expedients devised to counteract hurtful consequences.

The necessity of revising and extending the functions of certifying surgeons has long been advocated in this *JOURNAL* on grounds similar to those advanced by Dr. Laurie, but the manner in which this extension can be made has not yet been fully enough discussed to elaborate a scheme for effecting the purpose. Unfortunately there exist many dual authorities in sanitary work, whereby duties overlap, and one set of officers and of administrative authorities comes into collision, and sometimes antagonism, with another. For instance, sanitation is in the hands of the Home Office, of the Local Government Board, and of their subordinate departments. Even in certain sanitary matters the War and Foreign Offices claim a directing voice. So, likewise, when we descend from central offices to local governing bodies, we encounter councils of many sorts contending for power in sanitary affairs, in appointing officers of health and regulating their action, and especially in paying them. Among such miscellaneous bodies, of whom no special qualification can be predicated, what uniform opinions or practice can be expected?

It is with regard to these various and often discordant authorities that difficulties may be discerned in defining the limits of action of certifying surgeons, and in leaving them the independence they require for the execution of their duties on the extended plan desired.

There is one thing plain, that local control is inexpedient and mischievous when success demands uniformity and continuity of administration. This is sufficiently illustrated by the shifting of the executive for enforcing the Bakehouse Acts from factory inspectors to local authorities, and *vice versa*. And, alas! a new factor in factory legislation seems threatening in the shape of police supervision after the Continental fashion.

Dr. Laurie's address opens out many collateral questions which deserve consideration and discussion which cannot on the present occasion be entered upon. The Factory Act of the current year was hurried through Parliament—each political party being desirous to figure as the friend of the operative classes—without adequate discussion; and is on all hands recognized as an incomplete measure, that leaves to a future session the task of passing a consolidating and amending Act to remove anomalies and omissions patent in

the several Acts which have emerged into light as a result of increasing experience in the working of factory legislation.

A BRAVE DOCTOR.

THE gallant conduct of Dr. Charles Toller, of Ilfracombe, on October 2nd, appears to us deserving of conspicuous recognition by the public and by the profession to which he belongs. During the great gale of that day a gatherer of seaweed heard the cries of a man who, supported by a lifebelt, had managed to struggle on to the rocks at Hall's Bush in Lee Bay, a part of the coast which is well known to be extremely dangerous. The man was the sole survivor of the crew of a small schooner which had foundered in the early morning off Bull Point. The seaweed gatherer managed to remove the man from immediate danger and carried the news to Ilfracombe.

Dr. Toller, accompanied by police and coastguard officers, immediately determined to go to his assistance; but, finding it impossible at that time to pass along the lower level, they were obliged to proceed to the cliffs above the spot where the sailor had been seen. It was impossible for a boat at that time to approach the rocks, and the cliffs—at this point 150 feet high and nearly perpendicular—offered no path.

In this emergency Dr. Toller had himself lowered over the cliffs by life lines to the spot at which the sailor, who had now become unconscious, lay. He administered restoratives, and remained with him altogether for some three hours. In this perilous task he was assisted by the coastguard and policemen. Efforts were made to haul the sailor up the cliff; but this, with the appliances at hand, was found to be impossible. An attempt to reach the spot in an open boat also failed; but finally, in a different state of the tide, the Ilfracombe lifeboat succeeded in reaching the spot and rescuing the sailor, who was taken back to Ilfracombe. Unfortunately he died of exhaustion shortly after he was taken ashore.

It needs a good nerve, a sure eye, and a steady hand to endure without flinching to be lowered over a perpendicular cliff, 150 feet high, on a calm day, but in a gale of wind, when death seems to offer an alternative of being dashed to pieces on the cliffs or drowned in the surges, the act becomes one of real heroism. Our columns were filled last week with much sound advice to medical students commencing their studies. Dr. Toller's act is also a lesson teaching by that most effectual of all means, a splendid example teaching the lesson that a member of the medical profession must be ready for any emergency which may arise in the course of his calling, and that, putting aside ideas of self, he must allow no obstacle to interpose between him and his great duty of ministering to suffering. Dr. Toller, who received his medical education at St. Bartholomew's Hospital, was at one time house-surgeon to that hospital. His act has again reflected a peculiar credit upon that great institution, and not less upon the whole profession to which he belongs. That profession delights to honour those of its members who give to the world conspicuous instances of that virtue of self-devotion of which we have had in recent times not a few striking examples among our military and civilian brethren. We believe that it will be

the general wish of the profession that it should have the opportunity on this occasion of marking in some public manner its admiration of Dr. Toller's courage and endurance.

In honour of M. Pasteur the Paris Municipal Council have decided to give his name to the Boulevard de Vaugirard, which adjoins the Pasteur Institute.

The committee of the Pasteur Institute is not likely to meet before the end of the month to appoint a successor to the lamented founder. It is thought that Dr. Duclaux will be appointed director and Dr. Roux sub-director.

The Bradshaw Lecture, on Some New Vaso-dilators, will be delivered before the Royal College of Physicians of London, by Dr. J. B. Bradbury, Downing Professor of Medicine in the University of Cambridge, on Tuesday, November 12th, at 5 P.M., and not on November 7th, as originally announced.

The term of office of Dr. Argyll Robertson, the Senior Surgeon Oculist to the Edinburgh Royal Infirmary, has been extended for two years; Dr. George Mackay, the Senior Assistant, has now been promoted to the full status of Surgeon Oculist with a certain number of beds under his care; while Ernest E. Maddox, M.D., F.R.C.S. Edin., has been appointed Assistant Ophthalmic Surgeon.

The sixty-fifth session of the Harveian Society of London will commence on Thursday, October 17th at 8.30, at the Stafford Rooms, Tichborne Street, Edgware Road, when Dr. Symes Thompson will read a paper on The Climate of Egypt. All members of the profession are cordially invited to attend. The Harveian lectures for 1895 will be delivered by Dr. M. Handfield Jones in December.

SURGEON HINDE has been appointed the Principal Medical Officer of the Machakos, or central, province of British East Africa. Mr. Hinde, up to the date of his appointment, was in the service of the Congo Free State, and he will be remembered as having taken part in all the fighting against the Arabs on the Upper Congo, when, notwithstanding his status as medical officer, he was given command as a combatant, and eventually reached the rank of captain, and acted as Baron Dhanis's second in command.

THE SICK POOR IN IRISH WORKHOUSES: COOTEHILL.

We have often in our comments on our Commissioner's reports urged the desirability of better classification as a remedy for many of the evils which prevail in workhouses. But where is the advantage of a rigid separation of paupers into classes without its logical consequence—the treating each class according to its special needs? In the account of Cootehill Workhouse, the one bright spot in an inconceivably dreary picture is the remark that the nurse, in spite of squalid surroundings and the lack of nursing appliances, is able to make the condition of the sick one of comparative cleanliness and comfort, at least in the daytime. But the aged and infirm are far removed from the sphere of her influence, so is the nursery, so also are the feeble-minded. We do not mean to suggest that all these departments should be under the charge of one unhappy nurse, who is probably already overworked, but rather that when the day comes when the administration of our workhouses is admitted even by the Local Government Board to stand in need of reform, all those who by reason of sickness, of extreme youth, or of the helplessness of age require constant atten-

tion should be placed under the charge of trained attendants. The only reason for regretting the present tendency in England to separate the sick department from the rest of the workhouse is that the change occasionally leaves the aged and infirm entirely without trained assistance.

THE GENERAL MEDICAL COUNCIL.

THE next session of the General Medical Council will commence on Tuesday, November 23rd, and the meeting of the Executive Committee will be held on the preceding day. The alterations at the Council's house in Oxford Street, which has now become its freehold property, are making satisfactory progress. The improvements include the erection of what is practically a new Council Chamber, an apartment 30 feet square and 14 feet high. Special attention is being given to the ventilation of the chamber, and it is expected that the work of the Council will be expedited and much facilitated by the improved condition under which it will in future meet for the transaction of business. The sanitary arrangements, also, have been overhauled, and as it was found that the drainage was not in good condition, a new drain has been constructed leading into the deep sewer in Oxford Street. As this has involved excavating to the depth of some 40 feet, it has delayed somewhat the completion of the work, but it is anticipated that all will be in readiness for the meeting of the Council next month.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE first meeting of the Royal Medical and Chirurgical Society will be held on Tuesday, October 22nd, at 8.30 p.m., when a paper on Posture in its Relation to Surgical Operations under Anæsthetics, by Dr. Frederic Hewitt, Anæsthetist to the London Hospital, and Mr. Marmaduke Shield, Assistant-Surgeon to St. George's Hospital, will be read. The subject is one which must interest all branches of the profession; and as it is, we are informed, very thoroughly and carefully considered by the authors, it is anticipated that an important discussion will take place. The paper will be illustrated by a large number of diagrams and drawings.

KHAMA AT THE LONDON HOSPITAL.

KHAMA, King of Mashonaland, is showing a lively interest in English civilised life, and on Monday last, October 7th, paid a long visit to the London Hospital. The King was accompanied by three other chiefs and Mr. Willoughby, his interpreter, through whom he made numerous inquiries during his inspection of the wards, examining the beds and spring mattresses, ice safe, surgical appliances, etc., remarking frequently on the prevailing cleanliness. Khama is a tall, well-built man, with a quick and courteous manner. He asked many intelligent questions as to the management of the Institution, and whether the patients paid; also as to the position of sisters and nurses. In speaking his face presents a pleasing and intelligent expression. In the children's wards he made many friends among the little patients, with whom he shook hands, to their great delight; and he remarked of the nurse that the children "loved their new mother."

TYPICAL HABITUAL DRUNKARDS.

OUR statement last week that the London police court inebriate "repeater" Jane Cakebread was but a type of many similar cases has met with speedy proof. The Swansea journals have since recorded the 279th conviction of Ellen Sweeney at Swansea, in spite of local efforts to reclaim her. Had she received the same lighter sentences as Cakebread has experienced in London Sweeney would have attained to over a 300th conviction. But the Swansea magistrates, after having found prison and workhouse fail, hit upon a new course this year. After one release in a drunken

about she fell foul of her sister, and had to find a surety that she would keep the peace and be of good behaviour for six months. She of course was unable to keep from drink, so that the Bench were empowered to imprison her for the six months. On her release she offended again, and on a magisterial alternative of being bound over or going to the workhouse she chose the latter, where she has been for several months.

IRISH WORKHOUSE REFORM.

THE Local Government Board inspectors are taking up a position of much-needed and useful activity. We read of them appearing first on one Board and then on another. Major Fair is, we are glad to note, making war against the "harrow" beds; Dr. Browne, the medical inspector, is investigating a case of alleged neglect in the nursing of a pauper; the guardians of Granard Union are told that their hospital "is the worst in the country." All this is evidence that the conscience of the country is awaking to the general neglect of the lives and well-being of the unhappy inmates of the workhouses. At present the discussions are too much distinguished by a desire to shift the blame on to someone else. In our opinion it would be much wiser for everyone concerned to frankly admit that at least some share of the blame rests on themselves, and, as a sign of contrition and amendment, to work earnestly and honestly at the inevitable task of correcting the maladministration of the past. What is wanted at this juncture is first of all a clear idea of the line that reform should take, and then a united effort on the part of all members of the community to make such a reform possible.

THE IMMACULATES.

WE are really sorry that the Guardians of the South Dublin Union appear to be hurt at the report of our Commissioner. Our desire has been to help to bring about badly-needed improvements, and we have suggested what these should be. The Visiting Committee handed in the following report at the last meeting:

The attention of the Visiting Committee having been called to some paragraphs on the condition of the South Dublin Union Workhouse, published in the BRITISH MEDICAL JOURNAL and other newspapers, they beg to report, with reference thereto, that as the statements are evidently made with a predisposition to find fault, and are not supported by the actual state of the workhouse, the Committee consider they are not deserving of any attention of the guardians.

Mr. Lenehan was bold enough to say that he thought the report a fair one, but his opinion was of no avail at a meeting where all the other guardians appeared to think that everything went very well. As a matter of fact this feeling does not find much support outside the Board. We should like to have a specific denial of our specific statements. They were plain enough. Does the Visiting Committee say that they are untrue? Perhaps it is natural that a committee whose efficiency is questioned by the nature of our report should tell the guardians that our statements are not deserving of attention. We are pretty sure that an independent committee would not concur in that judgment.

MEDICAL MISSIONS.

IN the report of this Society for the year 1884-85, which has just been published, it is stated that the cause of medical missions has been heartily supported by the Society since 1885. The ways in which the Society helps are by the training of students, the building and furnishing of hospitals, and the maintenance of medical missions. The Society voted during the past year £1,000 for the training of female students, and £1,000 for the training of men, but the maintenance of medical missions is the most expensive part of the work. The Society is at present assisting medical missions at Freetown, Sierra Leone; at Mahonoro, in Madagascar; at St. Barnabas Mission, Pondoland West; at Dur-

ban, in Natal; at Dummaguden, Chalbasa, Nazareth, Haifa, at Pekin and in Corea; and at Metlakatla, in British Columbia. During the year the Society has added to this already extensive list.

TWO IN A BED.

It was reported at a meeting of the Edinburgh Town Council on October 8th that there were at the present time 359 patients in the City Hospital for infectious disease, the largest number that ever had been in the hospital at any one time, even including the period of the small-pox epidemic. There were, it appeared, an unusual number (22) of cases of typhoid fever for this season of the year. There were 279 cases of scarlet fever. It appears that in some cases two patients have to be put in one bed, so great is the pressure, or so deficient is the accommodation. A subcommittee of the Town Council has been visiting the proposed site of the new fever hospital, and determining where the new hospital shall be built, and where the temporary wooden erection now in the Queen's Park shall be placed when it is removed. The unfortunate thing is that Edinburgh is now face to face with the grave possibility of epidemic disease with absolutely inadequate hospital accommodation, although for some years the Public Health Committee of the Town Council have been looking at and reporting on sites almost *ad nauseam*; not only so, but the ratepayers are to be made to feel the matter more substantially than in the way of mere talk, since it has been resolved to add one penny to the rates on each pound of rental, in consequence, it is stated, of the excessive expenditure in connection with the small-pox epidemic. Altogether, one cannot say that Edinburgh public-health affairs are at a high-water mark just now. Indeed, there are not wanting those who urge that they are being considerably bungled.

A SCHOOL FOR CHILDREN SUFFERING FROM RINGWORM.

Ringworm, though pathologically insignificant, is a nuisance, and sometimes a calamity, to schoolmasters, and often a serious hindrance to the education of children. At the International Congress of Hygiene held in London in 1891 Mr. Malcolm Morris suggested that special schools for children suffering from ringworm should be established, in which systematic treatment could be carried out while the child's education was continued. As far as we are aware, no step has been taken to carry this suggestion into effect in this country, although the disease is particularly rife in our large cities, and is believed by some to be increasing in prevalence. In Paris, where ringworm is comparatively rare, attacking on an average only from 500 to 600 children a year, a school for children suffering from the disease was founded in connection with the Saint Louis Hospital in 1882. This school is now being enlarged, and when the work is completed—in about two years according to the estimate—it will comprise two divisions, sufficient for the reception of all the children afflicted with ringworm and other contagious affections of the scalp in the French capital. The school is to bear the name of the late Professor Lailier, the distinguished specialist, who gave a large part of his life to the care of sufferers from ringworm. One division is reserved for children with ringworm; the other is intended for cases of favus and alopecia areata. The dormitories are to contain 400 beds, but the school will accommodate 500 pupils, as it is found that a certain number of mothers decline to be separated from their children for the six or seven months usually required for treatment. These day pupils will remain at the hospital school all day, being taken home under proper supervision at night. The cost of the buildings now in course of erection for the purpose indicated is estimated at £60,000, of which sum £44,000 will be furnished from the proceeds of the *Paris Mutual*, and £16,000 will be

granted by the Municipal Council. A school on the same lines, though not on so large a scale, is in existence in Rome. The experience of the out-patient rooms of our hospitals shows that ringworm is far more prevalent in London than in Paris or any other Continental city, but in this pharisaical country the betting ring is not made to pay tribute to public charity, while the keepers of the public purse might with advantage take a lesson from the "unpractical" and "sentimental" foreigner. We commend the example of the Paris Municipal Council to the attention of the London School Board.

THE INDIAN MEDICAL SERVICE.

THE *Pioneer Mail* of September 4th, in an article on "Lessons of the Chitral Campaign," alluding to the medical arrangements, comments as follows: "Again, strict regulations are required regarding the entraining of field hospitals. As matters now stand doolies are sent by one train and bearers by another. The doolies too are carelessly mixed up with other goods, and thus delayed for days or even weeks en route to the railway base. These may seem small matters, but they all need attention. Looking further afield we see that the Indian Medical Service as now constituted could not possibly meet the requirements of an Indian army corps engaged in conflict with a powerful enemy." In the face of this, how are we to explain the official optimism of the Secretary of State for India, who, not very long before Parliament was prorogued, in reply to a question in the House of Commons stated that his military advisers had informed him that the Medical Staff "was considered sufficient for all requirements"?

THE ANDREW CLARK MEMORIAL FUND.

THE failure of the Andrew Clark Memorial Fund has now been admitted by those responsible for the form which the proposed memorial took. The sum received in subscriptions since the great meeting addressed by Mr. Gladstone some eighteen months ago is altogether paltry, and the total amount falls very far short of that which it was hoped might have been obtained, and which was absolutely necessary for the new wing of the London Hospital which it was designed to erect. This failure is on many accounts a matter for great regret. Sir Andrew Clark was a man who deserved well of his profession and of his generation. This failure of an attempt to link his memory with an important extension of the hospital which he served so long and so well will appear to cast an unmerited slur on his memory—a memory which is cherished by the medical profession as that of one who was a loyal champion of its best interests and its highest aspirations for the public weal. Mr. Gladstone, in a communication addressed to a weekly contemporary, writes: "Were I called upon to advise about it, I should be tempted to recommend that an application for a small subscription be made to every medical man in Great Britain. I know not whether it is now too late, but I think the main interest in the design is that of the great profession with which Sir Andrew Clark was identified in feeling and in history." The truth of the last sentence will be admitted. In fact, the response which Mr. Ernest Hart received to a circular issued from this office in December, 1893, made it sufficiently evident that the profession desired that Sir Andrew Clark's memory should be perpetuated by some worthy memorial. Within a few days a long list containing the names of some of the most representative men of the profession in all departments of practice was received. But it was found that the authorities of the London Hospital already had their scheme in hand, and so far advanced that plans were drawn. Thus, the form of the memorial had been settled without consultation with the profession which, as Mr. Gladstone says, was mainly interested, and, rather than risk compromising the success of the movement, it was thought best by Mr. Hart to ask those who had already expressed their approval of the proposal to create a memorial to act

on the committee then in process of organisation by the authorities of the London Hospital. The movement has ended in fiasco, and Mr. Gladstone in the letter quoted above appears to attribute some blame for lukewarmness to the medical profession. The profession, however, had not the opportunity of expressing its wishes on the form which the memorial should take. There are, no doubt, two opinions in the profession as to the degree in which hospitals are abused, but it will be admitted that there is a very widespread feeling that what we want is not an addition to the number of hospital beds, or to the number of patients treated gratuitously in hospitals, but a better distribution of the eleemosynary aid now given (of which the medical profession contributes the most important part), so that it may now reach only those for whose benefit it is designed. We make bold to assert that the general opinion of the medical profession is that the public advantage would have been better served by a scheme which would have contributed to the advancement of clinical medicine—to the extension of our knowledge of the manifestations of disease, greater accuracy in diagnosis, and increased precision in the use of remedies. It is to be feared that the opportunity has now passed, but there can be no doubt that Sir Andrew Clark would himself have been overjoyed to think that his name should be associated with an institute in London for the advancement of clinical medicine, of which he was throughout his life so ardent a student. In late years, when the demands of an enormous practice made the most serious calls on his time and energies, it was his custom to retain the services of a highly-skilled assistant, whose sole duty was to aid him in the study and investigation of the private cases which came under his care. Several of these gentlemen are now occupying posts of distinction. They were not in any sense secretaries, for Clark wrote all his own letters with his own hand; nor did they assist him in his practice in the ordinary sense of that phrase. Their part was entirely behind the scenes, so far as Sir Andrew Clark's patients were concerned. It was in the study and investigation of clinical problems which came before him that their services were required. Would it not have been wiser to have taken counsel from Andrew Clark's own opinions as evidenced by his practice, and to have founded in his memory an institute which would have given to other and less prosperous practitioners the facilities and skilled assistance which he provided for himself in the clinical study of disease?

THE IRISH PRISONS BOARD ON INEBRIATE PRISONERS.

In the seventeenth report of the General Prisons Board, Ireland, issued on October 4th, reference is made to the Inutility of imposing short sentences on inebriates and other old offenders. This, it is stated, is especially noticeable in the case of drunkards, who comprise 50 per cent. of the convicted prisoners in Ireland. From a curative point of view this system, the report adds, has admittedly proved a failure, while from a disciplinary point of view grave objection must be taken to sending habitual drunkards to prison, where, owing to their condition of health, they have in most cases to be treated as patients rather than as prisoners. The Board think it ought to be a question for consideration whether the law on this subject should not be amended, so that such inebriates, instead of being committed to prison for short terms, should be detained and treated in special institutions.

THE EXPERT INSPECTOR.

CARRYING matters to what appear their logical conclusions is not always a safe proceeding, and some writers in the general press seem to have been led into error by the apparent simplicity of the deductions which can be drawn from the remarks made by Dr. Laurie in his introductory lecture at St. Mary's Hospital. He pointed out the daily

growing necessity for the employment of experts in the inspection of the various trade processes which are now placed under the rule and governance of the Home Office, and showed that it was out of the question to look for the special knowledge required among ordinary inspectors who had been engaged in work of a different character. From this the not unnatural deduction has been arrived at that, even in the medical profession, specialism must begin at the beginning, and that a man intended for the sanitary service must devote himself from his youth up to that particular department of knowledge. "Why," we are asked, "should not the Government catch them when young?" and we are told that "there is an urgent need for systematic and continuous observation and recommendations such as can only be given by a medical expert put to the work when fresh from the hospitals and relieved from the necessity of obtaining a livelihood by private practice." In all this there is much truth; at the same time there is also underlying it a fallacy. The great value of a medical officer of health lies in the fact that he is a specialised medical man. It is far better to recruit the sanitary service from the mass of the profession, so long as the individuals chosen are qualified for their posts, than to organise the service in such a way as to exclude medical practitioners from obtaining access to it. A great deal of the success of the sanitary administration of this country is due to the fact that its members have so far been truly medical men. The tendency for men to go in for the sanitary service from the beginning, and to devote no more attention to purely medical work than is necessary to enable them to gain access to the *Register*, will turn out some very smart officials, who will apply their cut and dried knowledge with a precision and exactitude which will be pleasing to all town clerks; but they will not be as well fitted as truly medical officers would be to cope with the ever-varying phases of disease.

TYPHOID FEVER IN EAST LONDON.

DURING the past few weeks there has been a considerable increase in the number of cases of enteric fever notified in certain parts of the East of London. All over the metropolis there has been a somewhat increased prevalence of the disease, but in Poplar and the adjoining district of Bromley the number of cases during the four weeks ending September 21st was more than twice as great as in the corresponding period of last year. During the four weeks mentioned 28 cases were reported, the next week there were 4, the next 8, and this week up to the time of our report 5, making altogether 45 cases in a little less than seven weeks. The origin of the outbreak is not very apparent. There certainly had been a considerable increase in the number of cases of diarrhoea during the hot weather, but that had subsided almost coincidentally with the heavy rains by which the sewers had been flushed, and some time before the rise in the prevalence of enteric fever. There seems at present no reason to connect this outbreak with the milk supply, the cases being distributed fairly impartially over the district, and not being associated with the walk of any particular milkman. The cause of this local epidemic is being carefully inquired into by Dr. Alexander, the energetic medical officer of the districts, and by the sanitary officials of the County Council.

NUNS AS NURSES IN IRELAND.

WE have already referred briefly to this matter in the *JOURNAL* of September 28th, but the question is of such importance and the crisis in Ireland is so grave that we recur to the subject. It is most unfortunate that the question of creed has arisen to complicate the situation; we are quite sure that the Local Government Board has acted in the best interests of the poor inmates of the workhouses, but it is hard to induce our friends over the water to look at the action of the department with our eyes. The matter at issue lies in a nutshell: Are the sick in the workhouses to be

nursed by trained or untrained nurses? The addition of the word "trained" is not of the small importance that some of the critics in the local press would lead their readers to imagine; a trained nurse is a woman who has been taught her business in a school authorised to teach, and by a body qualified to teach. Now we do not meet with either of these qualifications in a workhouse infirmary; the experience there gained is undoubtedly most useful, but forasmuch as it is acquired without the benefit of being directed by those who are qualified to teach, it can only rank as amateur work; this experience also is limited to the style of work in that particular infirmary, and so has no received standard of efficiency. In the Mater Misericordie, Vincent's, and Jervis Street general hospitals in Dublin, which are under the direction of nuns, and where nuns have for years nursed, it has, we understand, been found advisable to change the system. Lay nurses are now trained there, and the nursing is done by the lay nurses, the nuns working in the domestic departments of those institutions. Thus in these hospitals under Roman Catholic management, there has been a voluntary admission that the old system was capable of improvement. A medical officer who has his infirmary worked by untrained nurses is crippled in the application of his skill to the treatment of his patient; he can go so far but no farther. Now we contend that it is essential to the proper equipment of a workhouse infirmary to retain the services of a doctor for the treatment of the inmates; the medical man should have his department properly provided with nurses, as well as drugs and instruments. We earnestly hope that wiser counsels will prevail, and that the services of the nuns, who, because they are a disciplined body of workers are most valuable, will not be lost to the paupers, because the sisters are not allowed to qualify themselves in the wards of a hospital. Workhouse reform is in the air, the times move on and the guardians must move with them, or they will find themselves superseded by those who are in sympathy with the age.

SUPERVISION OF TUBERCULOSIS AND DIPHTHERIA.

We have received from the Health Department, City of New York, a complete set of the various documents, letters, and forms, together with a culture outfit, employed by them in the supervision of all cases of diphtheria and tuberculosis. The methods employed are most thorough in nature. As they affect diphtheria, they have already been noticed in our columns, but the regulations affecting tuberculosis are of such importance that a brief description of the methods employed must prove acceptable to all. The attention of the Board was first directed to this subject in 1889, at the instance of Dr. J. D. Bryant, but it was not until Dr. H. M. Biggs, at the latter end of 1893, again called attention to the importance of the subject that any decided steps were taken. The results of these gentlemen's efforts are now embodied in a very complete system of supervision and prophylaxis, of which the main features are somewhat as follows: On the death or removal of a consumptive patient from premises which have been occupied by him, the medical sanitary inspector is required to visit such premises, and enforce the disinfection by the department of all infected articles; at the same time an order is issued by the Board enforcing, on the recommendation of the medical officer, the renovation or disinfection of the premises themselves. For the prevention and treatment of pulmonary tuberculosis the Board recognises the importance of early diagnosis, and are prepared to make bacteriological examinations of sputa at the request of physicians attending all cases not being treated in hospitals. In the case of patients being treated at public institutions, the Board compels the authorities to furnish a full report of each case, but in the case of private patients it contents itself by earnestly requesting the co-operation of the attendant practitioner. In addition there has been printed a very excellent circular (in English, German, Hebrew,

and Italian) setting forth clearly the infectious nature of the disease, and giving simple directions for diminishing the risk to such persons as have to live with consumptive patients. The obvious results of the work done thus far lie in the evident effects on the education of the people as to the infectious nature of tuberculosis and the means to be taken for its prevention; and in the destruction of sources of infection by the renovation of infected apartments. Although the report, which appeared in the *American Journal of the Medical Sciences* in January of last year, claims that for the current year there had been a much greater diminution in the death-rate than for any previous year, we suspect the real cause to lie, not in the method adopted of compulsory disinfection and renovation but in the good effects which invariably follow any increase in general knowledge relating to the *modus operandi* of health matters. And we suggest that even the stringent measures adopted and successfully carried out by the New York Medical Board cannot be put into operation in our own country, still almost as much could be done by the dissemination, among the people at large, of at least an elementary knowledge of the etiology of tuberculosis. Such a course would involve increased work on the part of the medical officers of health were no special arrangements made for its accomplishment. Undoubtedly such arrangements should be made, but a consideration as to their exact nature is beyond the scope of this note.

THE DIAGNOSIS OF BOVINE TUBERCULOSIS.

AFTER an extended trial of tuberculin as an aid to the diagnosis of tuberculosis in cattle Dr. Leonard Pearson, of the Pennsylvania State College, reports that it is a very reliable agent for determining the presence of tuberculosis in cattle, that when properly prepared and judiciously handled it does not produce disease, and that it is the only known means by which a positive diagnosis can be made in the early stages. According to the *Medical News*, from which we quote, Dr. Pearson, so far from accepting the view that it will produce the disease in susceptible animals, believes that in some cases it has exercised a curative influence. The tuberculin used was obtained in some instances from Professor Koch's laboratory, in others from the Bureau of Animal Industry at Washington, and in others again from the Agricultural Experiment Station, Delaware. The tuberculin manufactured at these three centres gave like results. For injection tuberculin is diluted with a 1 per cent. solution of carbolic acid in freshly boiled water to a strength of 10 per cent. The amount used varied with the condition of the animal, a larger dose being given to an emaciated animal, a probable victim of tuberculosis. Dr. Pearson points out that care should be taken to ascertain that any sample of tuberculin used for diagnostic purposes is really active, and he utters a warning against the attempt to obtain very large quantities of milk from individual cows. The strain thus put on the constitution renders the cows more susceptible to contract tuberculosis; "the aim should not be to discover how much it is possible for a cow to produce, but to discover how much she can produce with a reasonable amount of exertion and without detriment to her constitution."

EPIDEMIC TYPHOID AT SUNDERLAND.

THE epidemic of enteric fever through which the borough of Sunderland is at this present time passing is one which is attracting a considerable amount of interest, and not unnaturally, looking to the nature of the prevailing disease from the standpoint of its swift onset from comparative quiescence to that of epidemicity. In successive weeks from August 10th we are told that the cases newly arising in the borough have been respectively 14, 10, 13, and then a jump to 57, with a further stride to 104 and 106, and thereafter a decline to 83 and further to some 60 cases, the figures pointing, to our mind, to some new cause set agoing sud-

denly in some way. Indeed, the facts are not inconsistent with a milkspread epidemic, and again they would be met by water as a causative agent. To neither of these, however, does Dr. Harris, the late health officer of Sunderland, ascribe the present prevalence, but to the midden system in vogue in the town, concerning which he inveighed so strongly and persistently when in the borough. How far this may be so in the present circumstances we cannot pretend to estimate, but all questions will doubtless soon be answered now that, as we are informed, the Local Government Board have sent down a medical inspector to investigate the matter. Apart, however, altogether from the epidemic, the advice of Dr. Harris in his letter to the *Sunderland Herald* as to the need for the abolition of the midden system and the substitution thereof of a water carriage system of excrement is sound on all accounts, and deserves the serious attention of the Health and Building Committees to the important considerations which are involved. To learn of new houses being allowed to perpetuate the foul attachments of midden privies is to hear of retrogression in health principles, and for the sake of the town we trust this will at once cease, and the larger matter at the same time receive unhesitating support from the Town Council.

HOSPITAL ABUSE AT BRIGHTON.

DR. FRANCIS WARING calls our attention to the gross abuses which exist in the administration of the medical charities in Brighton. It is impossible to have any doubt as to the existence of abuse when we hear that, notwithstanding the fact that Brighton is one of the richest communities in the kingdom, 38,113 patients were last year admitted to the various hospitals and dispensaries of that town, although the whole population, including that of the sister town of Hove, amounts only to 130,000. The most startling facts, however, have relation to the lying-in charities for it appears that out of 3,704 births in Brighton and Hove during the year 1894, no fewer than 1,240 were attended by one charity alone, in addition to which some were attended in the Union, and others by a society for helping young women. It is impossible to believe for a moment that over one third of all the mothers in that district are fit objects of charity, yet the only alternative to that belief is that the charities of Brighton are badly managed, laxly administered, and, as a consequence, are grossly abused.

ALCOHOL IN IRISH WORKHOUSES.

It is satisfactory, from a compilation of various statistics from Government returns issued by the Irish Association for the Prevention of Intemperance, to find that there was a slight decrease in the cost of alcoholic intoxicants since 1891. The reduction is small, practically a diminution of 2d. per head. There are some curious features in the figures. As in previous returns the cost per inmate in the North Dublin Union is very different from that in the South Dublin Union, being 3s. 10d. in the former and only 1s. in the latter in 1893. Strange to say, the average expenditure in Belfast is the same as in North Dublin. It is evident that stimulants are given on no common principle. In the following unions no alcohol was administered in 1893; in Cloness, with 79 inmates on a daily average; in Manorcunningham, with 127; in Newry, with 213; in Salford, with 106; and Stranmillis, with 66. Westport and Newcastle follow with an average cost per head of 1d., Lurgan of 3d. Then the averages rise gradually up to the highest of 16s. 7d. The rate of reduction or of increase has also shown some apparent eccentricities. In short, the amounts consumed and the rate of cost per inmate present a maze of confusion and generalization which could hardly be surpassed in its chaotic bewilderment if the responsible officers had drawn for the liquor orders in a hat filled with the pauper's names. We are not informed how much of the intoxicants

has gone to officers' rations, how much to healthy paupers as an illegal reward for work, or how much has been prescribed for the sick. In the United Kingdom there has been a general decrease of some 60 per cent. during the past quarter of a century. The medical officers would be well advised if they made a special study of alcoholic liquors as dietetic and therapeutic articles, that they may order those dangerous remedies on some general, accurate, and sound scientific basis. Unless they set to this urgent work in earnest the existing chaos of alcoholic prescriptions will remain a reproach to an intelligent, valuable, and hardworked public service. The reform in associated and resolute inquiry of this kind is set on foot the better for the interests of the poor, the better for the administration of the Poor law, the better for the character and usefulness of the medical staff.

THE PILGRIMAGE QUESTION IN INDIA.

We are glad to see that when the revised Pilgrim Ships Bill, which has formed the subject of much controversy, came before the Viceregal Council of Simla on October 3rd, Prince Jehan Kader stated that the Mohammedans would hail the Bill as a great blessing. They in no way regarded it as a serious interference with religious freedom, and he hoped that the Secretary of State for India would sanction the measure. The Viceroy welcomed the attitude of moderation and good sense adopted by the Mohammedans, and said that the present Bill strengthened the case against unreasonable restrictions, and facilitated an early amendment of the existing conditions of pilgrimage. The Government of India did not consider all the restrictions of the Paris Convention necessary, but admitted that evils existed. They had no wish to place any obstacles or restrictions in the way of pilgrims, but only desired to render their religious duty more convenient and more consistent with safety and ordinary decency.

MEDICAL FEES FOR CERTIFYING CASES OF PAUPER LUNACY.

At a recent meeting of the Yeovil Board of Guardians a motion was made expressing disapproval by the Board of the increase of the payment of medical officers for certifying cases of pauper lunacy from half a guinea to one guinea. After some discussion the motion was carried by twenty-three votes to eighteen. The mover of the resolution believed in work being done at the least possible price, and that it was the duty of the Board to see that such was the case, and stated that his object was not to cheat the doctors, but to prevent the Board from sweating the ratepayers, and consequently that he brought forward the motion in the public interest, and thus supported a just and righteous economy. The Rev. Mr. Hardin, the Rev. Mr. Armstrong, and Dr. Colmer, on the other hand, maintained that the work of certifying pauper lunatics was onerous and responsible, and should be properly remunerated; and one member of the Board mentioned that the ordinary fee for passing a horse by a veterinary surgeon was one guinea, and, very rightly, he could not see why it should be less for certifying a pauper lunatic. We have no desire to claim that the fee of medical men should be ever large, but, considering the important and often difficult nature of the work of examining and certifying, or deciding not to certify an alleged lunatic as being such, the time that must be taken not only in examination but in preparing documents and copies of them, the risks of prosecution which are run by every medical man who does sign any such certificate, and the importance of having a skilled opinion on behalf of the interests of the alleged lunatic himself or herself, we think no medical practitioner should be asked to undertake the work for less than one guinea, and that the fee should be the same whether, on examination, the medical practitioner decides that the case is or is not a fit one for certification.

REPORTS ON THE NURSING AND ADMINISTRATION OF IRISH WORKHOUSES AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

III.—COOTEHILL UNION, CO. CAVAN.

We received a cordial welcome from Dr. Moorhead, the medical officer of the workhouse, who very kindly took us round, giving us every help in his power. The house, a grey stone building, stands close to the railway station, but about a mile from the town, on rising ground, facing south and north. It is what is styled a "second class house," a term describing its capacity (about 80 inmates), but not referring to its efficiency. Passing through the lodge and the body of the house we came to the

INFIRMARY.

As we looked at the exterior we were struck by the small slit apertures in the wall which serve as windows; they are a relic of the time when the therapeutic value of light and air was not understood. On the ground floor is the surgery, a small room full of drugs, and intended for the use of the medical officer; to the back is a disused ward holding 8 beds, now used for operations, or for the isolation of any case; opposite is a stone paved room intended for a men's day-room when the infirmary is full; the corresponding room on

the female side is used as the infirmary kitchen; its equipment is a wide open grate, over which was suspended a large cauldron, containing water, we believe, a large iron boiler containing the only water at hand for use, a dresser, some tin plates, mugs, a saucepan, and a frying pan. There is a close range in the nurse's kitchen upstairs.

THE WARDS.

It is almost impossible to convey to the reader the picture of squalor and wretchedness that greeted our eyes as we mounted the stairs to the first floor where the sick are; low narrow rooms, beds on each side, 6 on a side in the first ward, and about 4 on a side in the continuation ward; the beds close together, on one side (the north) square windows in heavy iron frames, and opposite to them the slit-like apertures already commented on, rough colour-washed walls, room open to the slates, an old-fashioned grate at one end, more chimney than fire, a bench and a few wooden armchairs; a bucket, chair, and a small table at one end completed the furniture. The bedsteads, close together, were many of them of the hospital pattern, but we saw the "harrow" bed in use besides. On the spring beds Dr. Moorhead uses a pad of old blanketing, this being, in his opinion, more sanitary than the hair mattress, as it can be washed, but on the "harrow" beds there was a tick filled with straw, and all the pillows are of straw. On the old bedsteads the tick and pillow are placed against the wall which is sometimes damp. As the square windows are neither weather-tight nor air-proof, the lower section has been boarded up, as some of the beds are across them; the whole of the ventilation is by means of the windows, the upper section swings on a pivot regulated by a toothed bar, but the frames are so heavy that it is a trial of strength to open them; such other openings as were in the roof or cornice were evidently out of gear. There are four

Fig. 1. - An infirmary ward, Cootehill Workhouse.

such wards, two on each side, and it must be observed that those at each end are over the lunatics' quarters.

THE PATIENTS

presented all the variety of ailment that is found in a general hospital, though the larger number are chronic cases; the wards were comparatively empty, as it was the summer; there were 22 patients in the wards, and 35 in all on the medical relief book. Several of these were in bed; a man with rheumatic arthritis, a severe case of pneumonia, a case of intestinal obstruction, ulceration of the leg, senile debility, and some good cases of recovery from operation; all surgical cases are dealt with here, as it is practically the hospital for the district. There is no lying-in ward, the women being confined in the general wards.

THE NURSE,

a trained midwife, has acquired her general training under the medical officer; her wards were clean and showed that much can be done for the sick by a zealous nurse, even under such unpromising circumstances. She has the assistance of an inmate in each ward, and on the male side there is a paid wardman, who works under the nurse, and "who has been of much service in inducing habits of order and cleanliness" (Dr. Moorhead's report). There is no night nurse. Dr. Moorhead selects the wardswomen from the older women, rejecting, if possible, those who are in the house with infants, the latter being likely to neglect the patients for the sake of their child. The nurse is responsible to the medical officer for the infirmary, and she also is held responsible for the custody of the lunatics. There are bells from the wards to the nurse's room.

THE FEVER HOSPITAL,

a two-storeyed building, stands at right angles to the main

building. It was built later than the infirmary, and exhibits many improvements in its structure and arrangement; the walls have a smooth surface; the wards are larger and more lofty; the windows are of fair size and face each other; the ceilings are plastered; but the fireplaces are of bad construction, and there are no internal sanitary appliances. A nurse—untrained, but experienced—is in charge, with proper help. At the time of our visit there were two patients, both convalescent, under her care; considering the decline of fever all over the country, the number of patients is never likely to be large, except in the event of an epidemic. Still, as the nurse has entire charge of the laundry and kitchen in the hospital her hands must be more than full when her patients are in the acute stage.

THE LUNATICS

were almost a sadder sight than the sick in the wards; they are in the two ends of the infirmary on the ground floor. Their quarters consist of the old cells disused by the medical officer, but not removed by the guardians, and the corridor and dayroom attached. In the corridor were 3 beds head to foot against the wall, and the other beds were in the dayroom, no furniture but a bench and a table, rough white-washed walls, a small window, and an old grate protected by bars. The recreation ground, as shown in our illustration, a stone-walled grass-grown yard, having a deal board as a seat; the woman standing up, herself feeble-minded, is the caretaker, the previous one having been discharged by the doctor for beating the poor creatures. These unhappy wretches are confined to this section, where neither treatment nor alleviation is possible. On the male side the section is the same, but many of the men were employed about the place.

Fig. 2.—Lunatics in the airing court, Cootestill Workhouse.

THE AIMING COURTS

attached to the infirmary are small grass-grown courts at the back of the building. In this house Dr. Moorhead has endeavoured to redeem the waste of desolation by laying them out somewhat like a garden, and placing a few seats for the old people, an act of kindness that has been much appreciated, the old people finding some relief to the monotony of their existence by the cultivation of the garden. The law of classification is so rigid that these poor people are practically imprisoned in the part of the house to which they are assigned. The rank grass that we saw in the lunatics' yard is anything but wholesome for the inmates.

We now turned our steps to the body of the house, where are the quarters for the

AGED MEN AND WOMEN.

These consist of long wards, low-pitched and unceiled, rough, whitewashed walls, windows at either end, and three at the side, a stove, harrow beds down each side, a few benches without backs, and a table at one end. The rooms were dirty, the patients were unkempt and unwashed, and as the only materials that we saw for the toilet were a tin basin and a dirty round towel this was not to be wondered at. This ward is approached through a concrete floored apartment called the dayroom, equally dirty and uninviting; most of the men were here, seated on a cross-bench in front of the comfortless grate; a long deal table, almost as black as the floor, was the only other furniture. On the female side most of the women were in the dormitory, many of them at needlework; their appearance was not quite so bad as that of the men, though the conditions in which they lived were the same. Both the men and women are in charge of an inmate, these caretakers themselves being old and infirm. In fine weather this class can sit under the sheds in the yard, but in the winter they are confined to their quarters. Before passing to the nursery we will describe the

SANITARY ARRANGEMENTS

in these and the sick wards. It must be understood that there are no indoor conveniences, and that the privies marked P in the sketch plan are at some distance from the wards, and therefore unavailable in bad weather or at night; to meet this difficulty the old people are provided with open pails or buckets; in the sick wards these buckets are enclosed in a wooden chair. It must also be observed that the infirm wards are locked on the outside from 7 P.M. until 6.30 A.M. The greater part of that time the ward is in darkness, and the only assistance available is such as the inmates can render to each other. The pails remain unemptied until the morning in both the sick and the infirm wards. We pictured to ourselves these wards locked up, the windows closed to husband the feeble warmth of the stove; the inmates on their narrow beds, from which they may slip to the floor in their weakness and there remain until the morning; the filthy-smelling buckets, some doubtless upset in the dark; no water to be had, no help available except in case of dire need; we turned away sick at heart that such things should be. In the sick wards the nurse is at hand, but there is no night nurse, and the excreta of the sick poison the air in those crowded wards. In the lunatic wards the same unsavoury method prevails, and the well-known dirty habits of the feeble-minded add to the foulness of the surroundings. The privies in this house are on the wagon system; a movable trough receives the soil, and when full is drawn out of a door at the back and wheeled on to the land. We noticed that the trough was neither cleansed or purified before being returned to the privy.

THE NURSERY

is close to the women's dayroom. It is a small room, having one window, rough walls, raftered ceiling, and an old grate set in the angle of the wall. We saw three infants in this nursery; one asleep in a wooden chair by the fire, its vomited food on its clothing and on the floor; another in a wooden cradle asleep; and the third sitting up, and roaring lustily for the attendant, who was not in the nursery. These infants were not clean or sweet; we were informed that their mothers were supposed to take care of them. We saw nothing sugges-

tive of a nursery—no toys, amusements, or pictures. The room opens on to a yard.

DOMESTIC AND OTHER APPLIANCES.

There are no baths either in the infirmary, the fever hospital, or the infirm wards, nor is any water laid on to these departments, except to the laundry. The water for the infirmary is obtained from a tank in the body of the house, and that for the body of the house from a large well, from which it is pumped up by the inmates into the tank. The movable bath, having to be filled and emptied by hand, is now practically disused from lack of labour. The kitchen and the laundry remain as they were constructed when the house was built: in the former, three large boilers each, with its separate fire—one for the stinabout, one for potatoes, and one for holding cold water; in the laundry two old wash-tubs, a copper, and a box filled with stones on rollers serves as a mangle. Both these offices were very dirty—a dirty pauper was head cook, and two women were splashing dirty clothes about in dirty water in the laundry. The sole cooking utensils that we saw were two saucepans and a frying pan. It is no wonder that Dr. Moorhead pathetically remarks in his report that it is no use his ordering meat, for he has no one to cook it. Under these circumstances we were not surprised to find that the dietary was as elementary as the appliances, consisting principally of porridge, milk and bread for the able-bodied and old people, and for the sick such food as could be cooked in the small ill-found kitchen in the infirmary.

RECOMMENDATIONS.

It has been our custom in concluding these reports to focus the results of the inspection; thus, we hope, giving some aid to the guardians in the work of reform; but in this case we find ourselves confronted with a building in all ways unsuitable for the work required of it, and, when the question of adaptation is considered, the cost of fitting it for the use of a modern hospital will be so large and the result so unsatisfactory that we hesitate to suggest it. As we considered the circumstances of the district and the proximity of workhouses quite in excess of the population, we saw a prospect of amalgamation leading to better classification and the more efficient treatment of the sick and infirm. The alternative is a new infirmary, which would be cheaper in the end than the attempt to patch and adapt an unsuitable building.

NENAGH WORKHOUSE INFIRMARY.

The inquiry into the alleged scandal in this house has ended most unsatisfactorily. It is evident that the medical officer, Dr. Moffitt, feeling dissatisfied with the arrangements made for the nursing of the wards during the night, made efforts to awaken the guardians to their responsibility. Of the wisdom of the action taken we may have our doubts, but we are thoroughly in sympathy with the effort made to secure the appointment of a trained nurse for the night, and we regret to read that the Board is content to go on as they have been doing. As long as the system of locking up helpless people during the night with no more responsible attendant than an inmate is persisted in, there will always be a possibility of old people dying whose lives might have been prolonged if skilled nursing had been at hand.

IRISH WORKHOUSE REFORM.

We note with pleasure that the Irish press is turning its attention to this question; the *Northern Whig* and the *Irish News*, besides giving full reports of the proceedings of the Boards of Guardians, have several editorial comments on the matter, and from the *Irish News* we gather that the Government intend to appoint a Royal Commission to inquire into the working of the Poor Laws. This subject the *News* says is "a most direct and very general interest for the good body of the people, and will, we trust, receive early and careful consideration from the Government. Few questions call so loudly for an exhaustive examination."

BIRKENHEAD WORKHOUSE.

The medical officer at Birkenhead is endeavouring to move his Board to revise the system of nursing in the workhouse infirmary. As we gather from the report of the proceedings of the Board, Dr. Stanfield has been drawing attention to the unsatisfactory manner in which the orders are interpreted by the nurses, and in so doing he wished to expose the weaknesses of the system that appoints an untrained staff, unsupervised by a committee, to undertake the nursing of the sick. We are glad to see that a committee is appointed to investigate both the charges brought by Dr. Stanfield against the individual nurses, and to inquire into the working of the system.

THE HOUSING AND NURSING OF THE SICK POOR.

Everyone must feel worried at the perpetual chronicle of the policy of obstruction on the part of responsible authorities in the numerous instances in the housing and nursing of the sick pauper, these instances are bound to come, and the guardians will be choosing the worst part of

they go with the stream instead of contesting each step. The Poplar Board of Guardians are at some proposals with the managers of the sick asylum; the workhouse is overrun with sick for whom there is neither the accommodation or the nursing staff, and their desire to transfer them to the asylum is met by serious delays on the part of the managers, leading to actual re-imprisonment, and it is hard to place the blame; but of this we are sure, that if the business of a company or of a private venture were transacted in the manner in which the affairs under the Local Government Board are managed the directors would soon be sent about their business.

BASINGSTOKE UNION INFIRMARY.

THE Board of Guardians of this Union had two propositions to consider at its last meeting, by which the admitted congestion in the infirmary might be relieved. One was to build a new infirmary; the other was to twist and turn the existing buildings, adapting here and altering there, so that the increased and increasing number of patients might be accommodated. At present the position of affairs is that at a meeting of the Board held on April 26th of this year a resolution to build a new infirmary to accommodate 40 patients, with proper administrative adjuncts, was carried. This resolution was the result of a discussion on the report of the Inspector Mr. Baldwin Fleming, who condemned the present infirmary as "too quiet and too solitary." At a subsequent meeting of the Board when other members were present, the whole question was reopened, and certain then present succeeded in carrying an adverse resolution and referring the matter back to a Committee with an alternative scheme to adapt the chapel and other parts of the building to meet the demand for more space. We sent our Commissioner to inspect the workhouse and report on the arrangements as at present made for the infirmary purposes, with the result that the report as published in the *British Medical Journal* of September 2nd shows that the scheme of patching as advised by a section of the Board will only result in disappointment and in the expenditure of the sum necessary for a new infirmary at no very recent date. At the last meeting of the Board, held September 20th, we note with much regret that the policy of the party in favour of patching has carried the day, and further we read that the argument that seemed to turn the scale was that so dear to the obstructive guardian, namely, that there may be a prospect, whether in the near or distant future is not stated, of some revolution in the condition of and provision for the aged and infirm; therefore let us do as little as we can. For this reason Basingstoke is going to patch and make the rent worse.

OPENING OF THE MEDICAL SCHOOLS:

INTRODUCTORY ADDRESSES.

ST. THOMAS'S HOSPITAL.

MEDICINE: ITS PAST AND FUTURE.

By Sir EDWIN ARNOLD, M.A., K.C.I.E., C.S.I., etc.

IN the course of the address (to which we referred briefly last week) delivered on the occasion of the distribution of prizes to the students of the Medical School, Sir Edwin Arnold said:

INTRODUCTION.

The first impulse of a very busy man when he has been asked to deliver an address is undoubtedly to excuse himself as politely as he can. That impulse may be described as automatic and instinctive. But when the honour fell unexpectedly upon me of being invited to distribute prizes here to-day to the students of the medical school of St. Thomas's Hospital, I could not consider the occasion ordinary. The profound respect which I feel for your noble profession; my true delight in its progress and advancing achievements; the firm hope I entertain of greater medical and surgical developments to come, which will by and by render human life more pleasant and more prolonged; my many friendships among the leading physicians and surgeons of the day; my own private gratitude to the skill and goodness of some among them; and my personal interest in your great and useful foundation of St. Thomas's—these, with other considerations, suppressed in me that "reflex" and automatic "No" which fatigue and the dread of apparent presumption must otherwise have enjoined.

You, gentlemen, begin by self devotion and fearless defiance of risks which others dread and shun. Your original choice is brave, your early ambition honest, your first steps hard and dogged by the spectre of examination; your daily work, even if ever so little elevated by enthusiasm and faith, is work that brings help and hope to your fellows, and constitutes you the common friends of all.

TRUE VICTORS.

Moreover, you are advancing like true victors in a march

of constantly augmenting conquests over that strange fascinating waste of twilight and wondering exploration which is called "science." There have been times when it was not particularly honourable to be a doctor. The specimens of medical and surgical practitioners whom we find held up to ridicule in the pages of Molière or in the pictures of El garth, deserved, as far as can be judged, the pity of immortal scorn in which their ignorance and pretensions have been placed by the genius of satire. Yet there were not wanting, even in times of Thomas Diaforus, serious and modest searchers after the secrets of healing, men imbued with the dignity and solemnity of their calling; and, indeed, I think we could find up every single age from Galen and Avicenna to Ambroise Paré and John Hunter with the names of truly great doctors. But your lot is cast in an epoch of such acceleration of knowledge, such expansion of methods and resources, such ever-increasing power of doing solid good to your kind, that the old satires have all died away. The new age frankly honours and values your vocation, in discharging which you yourselves move forward by rules more and more exact and less empirical.

Living men of 60 years or so belong entirely to the present benignant reign—and within that reign we can recognise, though lacking your closer observation, what prodigious progress has been accomplished by medicine and surgery, and, I may add, in the science of sanitation. It was one of the surgeons of St. Thomas's Hospital—the illustrious John Simon, F.R.S.—who may be said, in conjunction with Mr. Edwin Chadwick, to have actually invented public hygiene. These great benefactors, and their able assistants, had none of the knowledge which you all, in greater or in less degree, now possess about bacilli and bacteria; but by improved drainage, purer water supply, good paving and scavenging, removal of refuse, and prevention of overcrowding they succeeded in establishing such a difference between clean and unclean places that the way was paved for the fruitful discoveries which followed.

Now you have at ever-extending command the vast new region of bacteriology, wherein sunshine and daylight, and the wonderful natural forces of life, and those that are friendly amongst the microbes light on the side of your enlarging science, and, on our behalf against the "pestilence that slayeth in secret." A great authority has declared that "a day will come when—in London, in Berlin, in Paris man will not die of diphtheria, of typhoid, of scarlet fever, of cholera, or of tuberculosis any more than he dies in these cities to-day of the venom of snakes or of the tooth of wolves."

SNAKE POISON.

In connection, moreover with that promising subject of the antitoxins such as those for diphtheria and tetanus, there is some promise, be it observed, of injections which will neutralise snake poison. Professors Calmette in France, and Fraser of Edinburgh, after patient experiment with snake venom have apparently succeeded in rendering rabbits, and eventually horses, proof against doses of this 350 times stronger than an ordinarily lethal quantity.

TSETSE FLY.

Has anybody given thought in the same connection to what might be done to rescue the draught cattle and horses of South Africa from the tsetse fly? Whole belts of our growing empire there are cut off from trade by the poison of this tiny plague, which kills all horses, oxen and donkeys that it stings, yet has no power whatever upon the zebras, buffaloes, and wild beasts of the veldt. If the blood serum of these naturally acclimatised and adapted creatures of the same genera, properly applied, could give immunity to South African caravans, millions of money might be saved to the colony.

ANÆSTHETICS.

Let me take permission to tell you that what fills my own heart most with thankfulness, and causes me chiefly to congratulate you on these new days of therapeutic science, is the benign, the blessed discovery, and the now almost universal employment of anæsthetics. If you look into the history of that happy revolution, you will be warned against depreciating fresh ideas by noticing how sadly slow men are to take the hints which Nature gives to them of her very

choicest treasures of resource. Why did not anyone act upon what Sir Humphrey Davy had so long before learned and imparted about the properties of nitrous oxide? The key was already there, but not until many years afterwards did an almost casual hand (that of an American dentist) fit it into the golden door behind which sat waiting an angel of pity, kinder and more powerful than any Arabian fairy suddenly revealed in her divine beauty and bountifulness to any prince or magician of the *Thousand and One Nights*. Is there anything in human history which more sternly teaches that men must win every boon of Nature by his own ceaseless striving than that this simple chemical and physiological secret of chloroform should have lurked so sadly long in its easy formula, undeciphered, through all those waiting generations when pain was an omnipresent tyrant, whom science could not control, and the operating room a torture chamber, dreaded almost as much by the surgeon as by the sufferer? Think of those gallant sailors of Nelson at Trafalgar, whose bleeding stumps, in the gloom of the orlop deck, were plunged into hot pitch to stay the hemorrhage! One would almost expect that, for pity of such brave men, and for the sake of the countless tender women and children who age after age, so hopelessly endured, Telephorus, the God of Healing or Nature herself, would have burst the iron law of her impassive silence, and as Helen did in the *Odyssey* for the sorely-tried Greeks, have poured this nepenthe into the bitter cup of mortal life. I can remember the poetess, Emma Cook, whom as a boy I knew, when chloroform was still unknown, writing how

Lies that blench not in the reeling strife
Turn silent and white from the surgeon's knife.

Not until 1847 although Humphrey Davy had been so near the revelation, did the anæsthetic age commence, giving to your Art a sure control of anguish; to its boldest practice confidence, quiet, and leisure; and to those who have to lie under that knife a sweet and complete oblivion. I have myself known what it is to pass, fearless of the kind steel, into that world of black velvet tranquillity, of which your magic drugs now keep the gate; and to awake as good as healed, grateful beyond words for the soft spell of enchanted peace, and the sure and faithful skill.

Nurses.

I have met in this great Palace of Pain gentle and graceful presences which lead me to allude to one more great and happy change among many that has come upon your profession; I mean the education and employment of professional female nurses. A great physician once said in my hearing that the three most sovereign medicines he knew were hot water, fresh air, and good nursing. In your fathers' day, gentlemen, we had no good nursing; we had Mrs. Gamp and Mrs. Betsey Frig, or else heavy-handed and heavy-footed male attendants, very different in mind and manner and influence from the lightly-moving and softly-speaking woman, whose carefulness—intelligent, pitiful, but tranquil, trained, and governed—now smooths every sick pillow, and carries out faithfully and fearlessly the ordinances of the doctor. I do not know whether you, the surgeons and physicians, or we, your patients in *posse* or *en masse*, are most to be fascinated upon this admirable revolution in the hospital ward and the sick room. There is no doubt that it was primarily due to the example of that most compassionate and noble-hearted woman, Florence Nightingale, who went at the head of a band of nurses, many of good birth, to the Crimean war, and by demonstrating there and afterwards the immense advantages of skilled and high-class nursing, gave to her age the blessing of this modern system and to her sex a new, a suitable, and a most honourable vocation. You have greeted the name of Miss Nightingale with instant and hearty applause. That generous tribute to her—who in her old age and retirement is even now the centre of so much silent national affection—encourages me to remember that I am, after all, poet by nature and lecturer only by accident, and that in those dark hours of the Crimean war I wrote certain verses, which are perhaps brief enough to be on this occasion acceptable. If I am so bold as to revive them from their unprinted oblivion, it is because what they express of admiration and gratitude is applicable in a great degree to every good and dutiful nurse, here and elsewhere, who loyally discharges this new and most womanly function.

The lecturer then recited the subjoined lines:

If on this verse of mine
Those eyes ever shine
Whereto sore-wounded men have looked for life,
Think not that, for a rhyme,
Nor yet to suit the time,
I name thy name, best Victim in the strife,
But let it serve to say
That when men kneel to pray
Prayers rise for thee thine ear can never know,
And that thy gentle deed
For Heaven and for our need
Is in all hearts as deep as Love can go:

'Tis good that thy name springs
From two of Earth's fair things;
A stately city, and a sweet-voiced bird;
'Tis well that, in all homes
Where thy kind story comes,
And brave eyes find that pleasant sounds be heard,
On voices in night of fear
Like Night's birds—sweet to hear
Oh Strong Heart! set like city on a hill,
Ah! Watcher! worn and pale
Dear Florence Nightingale!
We give thee thanks for thy good work and will;
England is glad of thee,
Christ, for thy Charity
Take thee to joy when heart and hand are still.

INDIAN DOCTORS.

This topic tempts me to glance at another closely connected with it, which has always had my earnest interest and support—I mean the movement so excellently instituted and so successfully carried out by my most noble friend the Marchioness of Dufferin and Ava for the supply of English female doctors to India. In that country, by reason of its peculiar institutions, we are secure from any controversial questions as to the fitness of women for your profession. The customs of the *purdah* absolutely forbid the high-caste Indian ladies to avail themselves of male European skill. I was dining once in Jeypore at the table of Surgeon-Major Hendley, the able and trusted friend of the Maharajah, when a message came that the chief Qu-en had been taken ill and begged the advice of the British Hakeem. He went, and on returning told us that, although for seventeen years a familiar visitor of the palace, and the private adviser in many matters of the Rajpoot Prince, he had been obliged to suffer his head to be enveloped in a silken bag, and so equipped had been led into the Zenana, where he had felt the pulse of Her Highness, and had examined her with the stethoscope without seeing an atom more of his patient than a glimpse of one jewelled slipper through the strings of the bag. Here is a medical and surgical field, therefore, wide and unfiled, which might absorb any amount of feminine ability and devotion, if only proper public support be given; and I ardently entreat your countenance and assistance for it in the course of that professional influence to which I well know many among you are destined to rise.

VIVISECTION.

I shall take courage, since your kind attentiveness proves you convinced of the sincerity of my interest in your profession, to touch upon yet another topic, bristling, I know, with dangers from outside observers. I have read, in one of the able disquisitions already quoted, a paragraph dwelling upon Harvey's grand discovery of the circulation of the blood, where, after mentioning that that splendid revelation was the result of experiments performed upon living animals, the talented writer—a great living practitioner—goes on to say: "The whole fabric of modern medicine, the whole difference between the prospects of a sick man to-day, and his prospects two hundred years ago, rests absolutely upon vivisection."

I do not venture, in presence of knowledge and experience so much vaster and riper than mine can be upon such a matter to dispute or qualify that assertion, nor shall I as an individual take on myself to deny to conscientious science, as many persons deny whose motives and arguments I most deeply respect, the right claimed to pursue essential experiments at the cost of the pain and death of innocent creatures. If to give my own life under torture would certainly lead to the saving of very many other lives, I should hate and scorn myself if I had not the will so to die; and as between men and beasts I suppose it is true that we are "more than many sparrows." But my private feeling, founded upon an ever-growing sympathy

for the lower animals, an ever-increasing wonder at their gifts and capacities, and an ever-deepening sense of our human responsibility to them, was expressed in a phrase, which I confess was extravagant, used by me to a famous contemporary surgeon, who said: "What, Sir Edwin! May I not visit a cat to save the life of a bishop?" and I replied: "Yes, Sir Henry, on condition that you afterwards give the cat a public funeral in Westminster Abbey as a benefactor to the Church and to humanity." Of course that was paradox, but I am persuaded that all of you will understand me, and many will agree with me when I declare that this solemn right to succour pain by inflicting pain has its best foundation upon an immense reluctance to adopt such a necessity, an anxious economy of anguish in the act; in fine, a feeling not of the heedless experimentalist, but of the priest sacrificing victims for propitiation. I say again that I disclaim any pretension to teach mercy to you whose vocation has mercy for its watchword. I will not share with my age the fruit of patient physiological researches, and then hastily reproach those who have laboriously acquired them for the general good. But as regards my own sentiments, that which chiefly led me to write *The Light of Asia* was the boundless and beautiful tenderness of the Buddhist religion towards the lower animals, whose lives are so mysteriously related to our own, whose lot is so largely at our disposal, and who are to us much as we human beings are to that invisible almighty Power at the feet of which we have sometimes too little cause to wonder if we ask in vain for pity and clemency. Therefore I will be bold enough to-day to put in this humble plea for the dumb martyrs of vivisection, that they may be as few as possible, as mercifully dealt with as possible, and that it be held by the inner *religio medici* which every true doctor cannot but possess and profess, that the meanest living thing thus sentenced to suffer and to perish for mankind derives from its very doom a certain enhanced regard and a special consideration to which the conscience and him who is a gentleman as well as a doctor will never be insensible.

BUT MERCY NATURAL.

I am not here however, as I before remarked, to inculcate reverence for all forms of existence, and tenderness towards all suffering, upon those whose glorious vocation it is to be merciful, sympathetic, and conscientious. Very quickly must the chivalrous aspect of a good doctor's life lay hold of him, as is sufficiently shown by a memorial which I have observed in your chapel. A tablet there records how your fellow student in this medical school gave up his young life in the passionate desire to save that of some obscure and humble patient. To my thinking no ancient cathedral, no chapel of St. George at Windsor, or of Henry VII at Westminster, no shrine or temple, or sanctuary anywhere, can contain an epitaph more touching to peruse, more nobly commemorative of the dead, more splendidly honourable to the institution which trained him, and to-day trains, I doubt not, many like him. We have all of us lately read, too, of the heroism displayed by Surgeon-Captain Whitchurch in the fighting at Chitral on the Indian frontier—heroism graciously rewarded by Her Majesty, and such as casts a lustre upon the whole profession.

OWENS COLLEGE, MANCHESTER.

THE TEACHING OF PATHOLOGY.

By SHERIDAN DELÉPINE, M.B., C.M.,

Proctor Professor of Pathology in the Victoria University.

In the course of an introductory lecture delivered on the occasion of the opening of the new Pathological Department at the Owens College, on October 2nd, Professor Delépine said: We meet to-day under circumstances which are of considerable interest and importance. For the first time the new extensive lecture and work rooms which have been provided with wise munificence by the Council of the Owens College for the study of forensic medicine, physiology, and pathology are opened to students and other medical workers. It is not my place to tell you how, through the addition of these new buildings to the medical school, all the departments, besides those I just mentioned, have benefited. It

is enough to say that this College offers you now, in all branches of medicine, facilities for study second to none in the empire.

I will only refer to pathology, and I may say at once that it is perhaps in this department that the improvements to which I have just alluded will be most felt. In the old buildings the space at our disposal was very inadequate; now, on the contrary, each branch of pathology is provided with laboratories well adapted to the special studies which have to be conducted in them. I will perhaps help you to realize the importance of these advantages by giving you a general idea of the subject which we have to study together.

Pathology is nothing else than the "natural history of diseased organisms," and as such is a branch of pure biological science, and is based on the same methods of observation and research as other biological sciences. The word pathology means "the science of disease." A definition of disease is not easy to give, but I may perhaps say that it is "a reaction of a living organism to agents incompatible with the normal performance of function." The reaction consists in (a) alterations in the functions, (b) alterations in the chemical composition, (c) alterations in the structure of the tissues or organs of the animal affected. The study of these alterations forms the object of three practical branches of pathology—morbid physiology, very often spoken of as experimental pathology, though experiments are not confined to this branch only; morbid or pathological chemistry; morbid or pathological anatomy, including histology. This subdivision corresponds also to methods of investigation which are quite distinct, though all tending to the same end.

The morbid agents, or causes of disease, form the object of another branch of pathology—etiology. This part of the science has most important practical bearings. Every advance in our knowledge of causes makes prevention and cure more possible. Among the causes of disease which are now known, none are more important than those parasites to which the name of bacteria has been given; to these I should, however, add a certain number of protozoa. Our knowledge of the relations of these micro-organisms or microbes to various fermentations and diseases may be said to be of quite recent growth. Thirty years ago bacteriology did not exist. It is to the remarkable discoveries of the illustrious man whose death science is mourning to-day that we owe the first clear and complete conception of the nature of contagious diseases. The influence of Pasteur's work in medicine is difficult to overrate, for we can hardly in the present day conceive how any true and complete idea of some of the most common diseases could be obtained without any reference to their microbic origin.

As a striking instance I need only allude to what occurred between the years 1850 and 1863 in connection with anthrax or splenic fever, otherwise known as malignant pustule or woolsorters' disease, etc. In 1850 Davaine and Rayer had noticed that in the blood of animals dead of anthrax there were rod-shaped bacteria. They evidently did not in the least realise the importance of this discovery. But after Pasteur had communicated to the scientific world the results of his splendid researches on lactic acid, butyric, ammoniacal, and other fermentations, and had shown the far-reaching meaning of his discoveries, Davaine reconsidered his old observation. In 1863 and 1864, in important communications on "Le Sang de Rate," he came to the conclusion that the bacterium which he had seen thirteen years previously, and which we now know under the name of bacillus anthracis, was the cause of the disease.

In the same way, under the influence of Pasteur and Davaine's work, Villemin, who had proved by a number of careful experiments the contagious nature of tuberculosis, was led to infer the probable existence of a microbe as a cause of that disease. This suggestion was proved some seventeen years later to have been correct by Koch's brilliant discovery of the tubercle bacillus.

Charles Richet has so keen a sense of the influence which Pasteur has had on the development of modern pathology that he feels inclined to divide the history of medicine into two great eras—namely, that of medicine before Pasteur, and that of medicine after Pasteur.¹ This subdivision, I need not

¹ *Travaux du Laboratoire*, 1892, vol. II, p. 16.

say, is not likely to find general acceptance, and may possibly by many be considered a piece of Gallic exaggeration. We are perhaps too much under the influence of bacteriological doctrines to foresee how far they will retain the primary importance which even the most careful scientists attach to them at present.

It is, however, impossible to doubt the well-proved connection there is between the presence of certain microbes and the production of corresponding morbid states; many methods now used for the prevention of disease, based on the connections just mentioned, have yielded such confirmatory and practical results that bacteriology is becoming daily a more important science in connection with the department of public health.

The practical teaching of pathology has necessarily many aspects. In our new department special laboratories have been provided for the study of morbid anatomy and histology, pathological chemistry, experimental pathology, and bacteriology. These laboratories have been designed so as to make them suitable not only for teaching, but also for research.

It might be imagined from what I have said so far that a complete course of pathological lectures should cover the greater part of medicine and surgery, with the exception of what relates to treatment; but it has been generally accepted that, for convenience sake and in the interest of the student, a course of pathology should deal specially with (1) morbid anatomy and histology; (2) the physiological processes involved in the production of lesions; (3) the nature of the causes of disease.

Bulstrode has justly said that "an enlightened and refined empiricism is still at the basis of most methods of treating disease;" and, such being the case, you might wonder why so much time should be devoted to the purely scientific side of medicine. A little thought will show that the duty of a medical man does not consist simply in the blind application of rules transmitted to him by tradition. If such were the case we would be still groping in utter darkness.

One of the constant objects of the physician or surgeon is to improve his art. This can be done in part at the bedside by careful observation and comparison of results, but the ideas suggested by these observations can only be tested by anatomical observations and experiments, and it would be hardly fair to use the patients themselves for experimental purposes, however probable the chances of success might be. It is not less important to keep in mind that hypothetical conceptions which are so useful in scientific research are bad—I should even say dangerous—guides in practice until they have thoroughly been tested by careful observations and experiments. From this it is evident that although pathological theories have an important place in the development of medicine, these theories should hardly be the main object of any useful course of medicine considered as an art. We have had many sad instances in the past of the dangers of theoretical conceptions, and of their blind application in practice, by very great men; and we are not exempt from the same fault at the present day.

But putting aside the philosophical side of the question, I will say that pathology has a most important place in the education of a medical man. Only by a study of this branch may the student hope to realise the field which opens before him in the short time that he can devote to his medical studies.

It is only by having placed before him a systematic and comparatively short exposition of the various processes, whether rare or common, that may be observed in the diseased body (so far as we know them at present) that he may hope to obtain an idea of the probable relations of one form of disease to another. It is only in this way that he can hope to learn rapidly the probable connection between cause and effect. Such a knowledge must be useful to him in presence of rare cases, or of more ordinary cases with some unusual features. Then, although I have said that it is not wise to depart in practice from the empirical methods established by experience, it is equally evident that a man in possession of a greater number of facts may arrive at more sound conclusions than observers who had fewer facts to compare together.

This course will be divided into three important parts:—

1. General pathology, or more correctly general morbid anatomy and physiology, which deals with the alterations produced by disease in the structure, composition, and functions of the tissues. It is necessary to consider in connection with this part disorders of circulation, and to a certain extent of innervation, in so far as they influence the productions of cellular lesions.

2. Special pathology, which is chiefly concerned with the changes produced in each organ by the morbid processes studied more generally in the previous section.

3. Etiology, which treats of the various causes of disease and of the way they affect the living body.

It has been of late the fashion, in some quarters, to speak with a certain amount of contempt of morbid anatomy. I should, however, advise you to pay special attention to this branch of pathology. Anatomical changes in a great many instances have been the means of attracting the attention of observers to disorders of functions and to causes of disease which would otherwise have escaped their notice. No pathologist would at the present day think, as some of the older medical men did, that anatomical lesions were actually diseases, yet in many instances the nomenclature used at the bedside is still based on that old notion, so that you will constantly hear of patients suffering from cirrhosis of the liver, nephritis, softening of the brain, and unfortunately in many cases the diagnosis cannot go further.

It is only in anatomical lesions that we can at the present day find a solid basis for a classification of the phenomena of disease that will not lead to constant confusion through overlapping of the sections. Whilst during life the existence of a large number of diseases is known by a certain association of symptoms, after death the same diseases may be indicated even more clearly by a certain association of anatomical lesions.

Through morbid anatomy the identification of certain diseases has been made possible long before the actual cause was known. I need only mention tuberculosis as an instance of this. Thoughtful physicians and surgeons have always taken a keen interest in morbid anatomy. The reasons for this are simple:

(1) The symptoms observed during life are often evanescent, and very often not evident at the time when a patient is under observation. (2) Many of the physical signs require considerable technical skill and experience to be recognised and properly interpreted. One observer is not always certain that he hears or feels exactly what another observer has found or felt. (3) Secondary phenomena often obscure the primary lesions. (4) Patients for some reason or other have often a desire to mislead their medical attendant by fanciful stories.

On the other hand, in the *post-mortem* room (1) one has mostly to deal with material or organic traces of disease, which are not liable to become obliterated except under special and definite conditions. (2) The structural changes produced by disease are few in number, and the complete effects resulting from their various combinations can be analysed with a considerable amount of accuracy. (3) The lesions themselves are objects capable of being accurately described and compared one with the other. They can be depicted and even preserved in our museums in such a way that it becomes possible for a man to compare his own observations with those of numerous other previous or contemporary observers.

By tracing carefully the connections between symptoms observed during life and lesions observed after death, the clinical observations of one observer can be compared with those of another in such a way as to leave little room for the disturbing influence of the personal equation. Anatomical lesions give us therefore the best means to compare and check our own observations and those of others; and though pathological anatomy gives but a very limited knowledge of disease, it provides the only firm basis on which to arrange the facts connected with disease.

KING'S COLLEGE, LONDON.

The physiological laboratory has been enlarged by the addition of two extra rooms. One of these has been fitted with

motor, shafting, and the necessary apparatus for conducting an advanced course of experimental physiology; the other is a dark room for photographic purposes. The lecture room has been also improved by fitting it with dark blinds for lantern demonstrations.

MASON COLLEGE, BIRMINGHAM.

The session at Mason College was opened with a public meeting in the large Lecture Theatre. The President of the College, Mr. Oliver Pemberton, F.R.C.S., occupied the chair, and was supported by the trustees of the College, the professors, and lecturers. There was a very large attendance. The President, in his opening speech, called attention to the fact that it was the sixteenth anniversary of the founding of the College by Sir Josiah Mason and the fourth anniversary of the transference of the Queen's Faculty of Medicine. By this event, the Birmingham School of Medicine, founded seventy years ago by William Sands Cox, had gained new life and strength, and stood at that moment on a level with the best known and most distinguished of its provincial brethren. The Principal, Dr. Heath, introduced the prize winners in the Faculties of Arts and Sciences, and Professor Windle (Dean of the Medical Faculty) introduced those of the medical school. After the distribution of prizes had taken place, Professor Percy Frankland delivered the inaugural address on *Pasteur and his Work: the Debt of Medicine to Chemistry*. The address has been reported in last week's issue. At its close Dr. Frankland received an enthusiastic vote of thanks from the meeting, and the proceedings terminated.

THE SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY.

ADDRESS BY DR. FREDERICK ROBERTS.

At the opening of the fifty-fourth session of the School of Pharmacy last week, the President presented to a representative of the Austro-Hungarian Embassy the Haubury Medal, which had been awarded to Professor Vogl of Vienna. In making the presentation Mr. Cartighe said that Professor Vogl was the father of pharmacognosy. It was reported that eighty-three students had attended the school during the fifty-third session. The prizes were then presented to the successful students. Dr. Frederick T. Roberts, Professor of Medicine in University College, then delivered the Inaugural Sessional Address. After some introductory remarks and a brief reference to the history of the Society, he spoke to the students of the responsibilities of pharmacy, and impressed upon them the need for taking the utmost advantage of the excellent means of instruction and training, both scientific and practical, which the school afforded. Turning, then, to more general topics, he said that there should be nothing approaching want of harmony between the medical profession and pharmacists. They ought to work together for the common good. In a state of perfect social order the one would really be the complement of the other. The medical profession claimed from the pharmacists protection against certain dangers and evils. In the first place it looked to them to guarantee that drugs supplied to patients were efficient, active, pure, and unadulterated. Deliberate substitution of drugs or systematic adulteration was an iniquitous variety of fraud which ought to be punished by something more than a fine. Dr. Roberts then touched upon the number and variety of preparations and compounds now so extensively advertised, and, while acknowledging that a debt of gratitude was owing to many pharmaceutical and manufacturing chemists of honourable type, he thought it decidedly wrong that so many drugs, some of them very powerful and even dangerous, should be supplied to the public in various portable forms, to be used to any extent at their own discretion. He deprecated also the extreme haste with which new drugs and special preparations were advertised before they had been fairly studied or tested. With regard to the long-established custom of medical men dispensing and sending out their own medicines, he said that he did not see how the system could be changed on a general or even on a large scale for many a day to come, especially in the smaller towns and country districts. For the prescribing chemist there was, Dr. Roberts declared emphatically, no excuse whatever. He had not been educated or trained for such a duty, and to

treat patients merely on their own statement as to what was the matter with them was wrong in principle and disastrous in consequences. He acknowledged with pain that there were practices prevalent among a certain class of medical men not one whit better than those of the prescribing chemist. He said that the running of "cheap dispensaries," where "advice and medicines" were supplied to all comers without the slightest pretension to "clinical investigation" and, as a rule, at a figure that he felt sure would make them blush if he mentioned it, and the extensive employment by medical men of "unqualified assistants," who were absolutely ignorant and incapable, and not a few of whom were but the wreck of immoral and degraded lives, were standing blot upon our profession, and it was a scandal that it was possible for such practices to continue. At the conclusion of the address a cordial vote of thanks was moved by the President, seconded by the Vice-President (Mr. Harrison), and carried by acclamation.

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held in the Council Room of the Association, at No. 429, Strand (corner of Agar Street), London, on Wednesday the 23rd day of October next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary*.

September, 1895.

ELECTION OF MEMBERS.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, *General Secretary*.

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

MEMBERS are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the office of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 2 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

DORSET AND WEST HANTS BRANCH.—The next meeting will be held at Bournemouth on Wednesday, October 18th. The business meeting will be held at the Hotel Burlington at 8.15 P.M. Agenda:—Election of officers for 1895, namely, President, Vice-Presidents, Honorary Treasurers and Secretaries. Place of the May meeting. Dr. Lush to move: "That a donation of 5 guineas be granted to the British Medical Benevolent Fund." Address by Dr. Radcliffe Crocker: *The Treatment of Inflammations of the Skin*. Communications:—Dr. Ramsay: (1) *The Pathology and Treatment of Appendicitis*, with short notes on nine cases of Removal of the Appendix Cæci; (2) *Uterus Removed by Rapid Hysterectomy*; (3) *Specimen showing New Method of Wiring the Psoas*. Mr. Vernon: *A Case of Fractured Olecranon treated by Suture*. Dr. Lawrie: (1) *A Case of Oophorectomy for Relief of Reflex Symptoms*; (2) *Removal of a Large Ovarian Tumour*. Mr. Charlton and Dr. Evans: *A Case of Castration for Prostatic Disease*. Dr. Ransome, F.R.S.: *The Act of Congress*. Dinner at the hotel at 6 P.M. (charge 6s. each, without wine). It is suggested that members having under their care interesting cases of skin diseases should bring them to the meeting. The nearest stations to Bournemouth are Poole and Bournemouth East.—WILLIAM VAWDOBY, 1, Col. M.D. Weymouth, C. H. WATTS PARRISON, WIMBORNE, Honorary Secretaries.

SOUTH-WESTERN BRANCH.—A very kind invitation has been received from the President and members of the Dorset and West Hants Branch to the South-Western Branch to the next meeting, which will be held at Bournemouth, Bournemouth, on Wednesday, October 18th, when Dr. Radcliffe Crocker, Physician to the Skin Department, University College Hospital, will give an address on *The Treatment of Inflammations of the*

FLIN. Those members who purpose attending are requested to send their names before October 1st to the Honorary Secretary, W. V. Lush, M.D., 12, Frederick Place, Weymouth, who has kindly promised to forward the agenda and other particulars.—W. GORDON, Honorary Secretary, Barnfield Lodge, Exeter.

STIRLING, KINROSS, AND CLACKMANNAN BRANCH.—The autumn meeting of this Branch will be held in the Station Hotel, Stirling, on Tuesday, October 22nd, at 3 P.M. The election of office-bearers for the year will take place and other business postponed at summer meeting will be transacted. The President (Dr. J. C. McVail) will deliver his Presidential address, entitled *Gleanings from Practice*. Further particulars by circular to members.—G. J. LAUREN, Honorary Secretary, Stirling.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The first meeting of the season will be held—by kind invitation of Dr. Adams—at Brooke House, Upper Clapton, on Thursday, October 11th, at 8.30 P.M. The chair will be taken by Dr. Daly, Vice-President of the District. Sir William Priestley, M.D., President of the Branch, will read a paper on *Some Recent Observations on Infant Feeding*. Visitors will be cordially welcomed.—HERBERT E. POWELL, Honorary Secretary, Glenarm House, Upper Clapton.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.—A meeting of the District will be held at St. Bartholomew's Hospital, Rochester, on Friday, October 12th, at 4 P.M. Mr. J. Holroyde will be in the chair. The dinner will take place at the Bull Hotel, at 5.30 P.M. Charge 6s. 6d., exclusive of wine. To facilitate the arrangements, gentlemen who intend to dine are particularly requested to signify their intention to the Chairman, Mr. J. Holroyde, Camden House, Chatham, not later than Tuesday, October 14th. All members of the South Eastern Branch are entitled to attend this meeting and to introduce professional friends. Communications: Mr. J. H. Openshaw: *Symptoms, Pathology, and Treatment of Congenital Dislocation of the Hip-joint*. Mr. T. F. Hugh Smith: *A case of Graves's Disease and Myxædema, after Treatment with Thyroid gland*. Dr. Ground: *On the Position of the Government with regard to Proprietary Remedies*.—E. GROUND, M.D., Honorary Secretary, 1, Ashford Road, Maidstone.

SOUTH-EASTERN BRANCH: WEST SUSSEX DISTRICT.—The next meeting will be held at the Infirmary, Chichester, on Wednesday, October 15th, 1895. Dr. Paxton will preside. Agenda: To fix the place of the next meeting, and to nominate a member to preside at it. Discussion on the Registration of Midwives, to be opened by Mr. G. B. Collett. Paper by Mr. Hilton Pollard on *Empyema*. Notes on a case of *Leishmaniasis* by Dr. Paxton. Meeting at 3.15 P.M. Dinner at 5.15 P.M. at the Dolphin Hotel; Charge 6s., exclusive of wine.—FRANK HINDS, Honorary Secretary, 14, The Square, Worthing.

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Radcliffe Infirmary, Oxford, at 3.15 P.M. on Friday, October 26th. Gentlemen intending to read papers or show cases, etc., are requested to give notice to the Honorary Secretary, Mr. W. LEWIS MORGAN, 37, Broad Street, Oxford, on or before October 6th.

SOUTHERN BRANCH: SOUTH-EAST HANTS DISTRICT.—The next half-yearly meeting will be held on Friday, November 1st, at 4 P.M., at the Medical Library, 5 Pondenoke Road, Portsmouth. Gentlemen desirous of reading papers or of exhibiting cases or specimens are requested to communicate with G. C. CLARKE, Honorary Secretary, 37, Elm Grove, Southsea.

NORTH OF IRELAND BRANCH.—The autumn meeting of this Branch will be held in the Royal Hospital, Belfast, on Thursday, October 31st, 1895, at 10 noon. Gentlemen who wish to read papers, show patients, or bring any other business before the meeting, will kindly communicate, as early as convenient, with JOHN CAMPBELL, M.D., F.R.C.S., Honorary Secretary, 21, Great Victoria Street, Belfast.

SHROPSHIRE AND MID-WALES BRANCH.—The annual general meeting will be held at the Salop Infirmary on Tuesday, October 1st, at 3 o'clock. Papers:—The President: *On the Need for Further Legislation for Insanities*. Dr. W. N. Thurnfield: *On the Exit Gates of Infection in Scarlet Fever and Typhoid*. Dr. Alfred Edmonds: *On the Pathology and Treatment of Acute and Chronic*. Dr. Fred. Edge: *On Vaginal Constriction*. Mr. T. J. Webb will demonstrate an improved method for obtaining pictures of mucous membranes for diagnostic purposes. Cases will be shown by Mr. J. McCarty, Dr. Llewellyn, and Mr. Cress. The annual dinner will be held at the Manor Hall at 6 P.M. Dinner tickets (exclusive of wine and cash) 10s. Members have the privilege of introducing friends to the dinner.—H. WILLOUGHBY GARDNER, Honorary Secretary, Swan Hill, Shrewsbury.

WEST HANTS BRANCH.—The autumn meeting of this Branch will be held at the Railway Hotel, Tisbury, on Friday, October 26th, at 5 P.M. Dinner at 5.30. The subject as settled by the Council for discussion after dinner will be Club Practice, and the discussion will be opened by Mr. Abbott. Short papers or cases may be taken before dinner, and others afterwards. The Honorary Secretary will be glad to receive notice of any case or paper to be communicated to the meeting.—W. M. ABRAHAM, M.D., Honorary Secretary, Tisbury.

HANTS COUNTIES BRANCH. A meeting of this Branch will be held at Exeter on Friday, October 26th. Members desirous of reading papers, etc., please communicate with R. DUNDAS HILM, Honorary Secretary, Exeter.

SOUTH MIDLAND BRANCH.

The autumn meeting of this Branch was held at the Bull Hotel, Olney, on October 3rd, fourteen members and one visitor being present; Dr. A. H. JONES, President of the Branch, in the chair.

Minutes.—The minutes of the last (annual) meeting were read, and a report was presented from the Committee of Management, both being confirmed.

Papers and Cases.—Mr. R. A. MILLIGAN read *Two Cases of Intestinal Obstruction successfully treated by Abdominal Section*.—Mr. G. A. PRACTICAL read *Some Cases of Ovariectomy*, entering into a great many interesting details.—Both the papers led to good and prolonged discussions, in which most of the members present took part.—A proposal on a medico-ethical question, set down in the name of Mr. W. H. Bull, was, in consequence of his absence, deferred to a future meeting.

Votes of thanks were passed to the Chairman and to the readers of papers, and the meeting terminated.

EAST ANGLIAN BRANCH.

A MEETING of this Branch was held at Thetford on September 26th, Mr. G. E. JEAFFRESON, President, in the chair.

New Members.—The following gentleman was elected a member of the Association and Branch: Percy Graham Gilmore, M.R.C.S., L.R.C.P., Gorleston, Yarmouth. The following members of the Association were elected members of the East Anglian Branch: Elizabeth Garrett Anderson, M.D., Aldeburgh, Suffolk, and 4, Upper Berkeley Street, London; William Edward Baylie, M.R.C.S., L.S.A., Yareford, Suffolk; Francis Augustus Brooks, M.D., Felixstowe, Suffolk; Benjamin S. Brown, L.R.C.P., L.R.C.S. Edin., Saxlingham, Norfolk; Eleanor I. Dodson, M.D., Norwich; William Gloag Gallatly, M.B., Northwold, Norfolk.

Papers.—Dr. PEMBROKE MINAS read *Antiquarian Notes on Thetford*, and Dr. EVERLEY showed books, mainly historical, relating to Thetford and its Chalybeate Spa.

The Registration of Midwives.—The Committee appointed at the Framlingham meeting to consider the registration of midwives presented the following report:

a. It is evident that in the present state of public opinion some improvement in the attendance on the very poor by the very poor during midwifery is imperative.

b. It is also evident that, although at the present moment in abeyance, legislation to that end is imminent.

c. Therefore your Committee, consisting of E. G. Barnes, M.D., A. C. Mayo, M.R.C.S., and A. R. Manby, M.D., in accordance with the directions received by them at the annual meeting of the East Anglian Branch at Framlingham, present the following report as the result of their consideration of the matter at issue.

d. No legislation can be permitted which aims exclusively at (or in the least degree tends towards) the licensing of a lower grade of practitioners. Because by so doing (1) the interests of the profession will be weakened; (2) the confidence of the public in the perfection of medical education will be lessened; and (3), according to the opinion of eminent lawyers, the foundations of all existing Bills for the education and licensing of medical practitioners will be sapped.

e. Midwives to act alone, even in the simplest cases, with safety, must be as perfectly educated in anatomy, physiology, and the collateral sciences of medicine and surgery as an ordinary general practitioner, because it is impossible to predict that any given case may not become a seriously complicated one, nor is it possible without such knowledge to realise the distinction between a case of difficulty and a natural labour sufficiently early to guard against danger to the mother or child, or both.

f. Such education cannot be obtained in the short space of time (three months) spoken of in the Midwives Registration Bill of 1895 and hitherto allowed as sufficient for the training of a midwife.

g. Therefore the safety of the public would be in jeopardy, and the poor who cannot afford to employ more skilled attendants would suffer at their most dangerous times, a condition of things absolutely incongruous in a paternal country where unqualified attendance on paupers is, although permissible to the rich, illegal for the treatment of the simplest disorders, for example, constipation, etc.

A. And, moreover, nothing is suggested that could prevent the admittance of male as well as female practitioners, so that under the protection of a midwifery diploma, chemists, quacks, and unqualified assistants could be actually admitted to the *Register* and licensed to practise obstetrics, pædiatrics, etc., with impunity.

I. A state of things which would be eagerly seized by a large mass of unscrupulous persons—and even in its least objectionable form would once again encourage the employment, by medical men, of unqualified assistants at branch establishments (which is rightly held to constitute covering)—and would enable the ratepayers, Boards of Guardians, etc., for the sake of saving their funds, to entirely refuse the extra fees now allowed for parochial midwifery, and to station in each village a licensed midwife under control of the district council, who would not be able to claim skilled assistance, and who, therefore, would increase the bill of mortality.

J. None of these objections would apply to nurses trained after the manner of the best medical and surgical nurses, who would be licensed and registered to work under the direction of any properly qualified medical man wanting them, and who would be liable to be removed from the *Register* and debarred from practice if they wilfully attended alone to any obstetric case, however simple or natural.

K. Your Committee therefore recommend the Bill of the Parliamentary Bills Committee of the British Medical Association, and cordially endorse the vote passed at the late Exeter Hall meeting in support of Mr. Lawson Tait's amendment:

That we, the members of the British Medical Association, while anxious to improve the training and supervision, and, if need be, to support a practical scheme for the registration of medical, surgical, and midwifery nurses, emphatically condemn any proposal which has for its object the formation of a class of medical or surgical or midwifery practitioners other than those recognised under the Medical Act 1858 as now existing.

L. Your Committee are further of opinion that a Midwives diploma, issued by the Obstetrical Society, or by similar bodies, is misleading to the public and injurious to the honour and interests of the profession.

A. C. MAYO.
E. G. BARNES.
A. R. MANN.

After discussion, it was unanimously resolved, on the proposition of Dr. WILLIAM CROWFOOT, seconded by Dr. BARTON, "that the report be received and adopted."

Communications.—Dr. W. S. A. GRIFFITH (London) read a paper on the Early Diagnosis of Cancer of the Uterus, and the Cases Suitable for Operative Treatment.—Dr. MARY SCHARLIEB (London) read a paper on Our Duty towards Women who Suffer from Abnormal Discharges or Pains, especially about the time of the Menopause. In the discussion which followed, the following members took part: Dr. GARRETT ANDERSON, Dr. W. M. CROWFOOT, Mr. MORSE, Mr. BURTON, Dr. BEVERLEY, Dr. DOUTY, Dr. BLAKE, and the PRESIDENT.

Cases.—The following were shown:—Mr. MORSE: Specimen of Cancer of the Cervix Uteri removed fifteen months since and now recurrent. Specimen of Cancer of the Cervix with pregnancy at the sixth month, the foetus removed by abdominal section and the uterus by vaginal hysterectomy.—Mr. HARRIS: Case of Multiple Sarcoma.—Dr. BARTON: (1) Case of General Paralysis of the Insane; (2) Case of Transverse Myelitis (lumbar origin); (3) Case of Double Hemiplegia.—Dr. BURTON FANNING: (1) Case of Exophthalmic Goitre in a man recovering under treatment with Thyroid Gland; (2) Case of Lead Poisoning.—Mr. D. DAY: (1) Specimen of Intestine successfully removed by Enterectomy with Murphy's Button; (2) Bones from Knee-Joints affected with Rheumatoid Arthritis.

Hospitality of Local Practitioners.—Fifty-three members and visitors were present at the meeting. They were hospitably entertained by the medical men of Thetford after the meeting.

At a recent meeting of the trustees of Jefferson Medical College, Philadelphia, the honorary degree of LL.D. was conferred on Dr. John Collins Warren, Professor of Surgery in Harvard University.

SPECIAL CORRESPONDENCE.

PARIS.

Funeral of M. Pasteur.—M. Pasteur's Will.—Hospital Districts. General News.

THE funeral of M. Pasteur took place on October 5th with much pomp and circumstance. The Government, the army, the university, public bodies, learned societies, and the general public were present to show their reverence for the illustrious dead and their appreciation of his work. The quiet Rue Dutot, in which the Pasteur Institute is situated, was the scene of much bustle whilst the remains were lying in state in that temple of science raised by his own efforts. At 8 o'clock on Saturday, October 5th, a detachment of police took possession of the street with strict orders not to let anyone but those invited to the ceremony to enter the Pasteur Institute. The outer oaken coffin had been replaced by one in ebony, enclosing a leaden one and a pine coffin. The members of the Pasteur family were assembled round the catafalque. Those persons invited to the ceremony moved in procession round the bier, bowing respectfully to the afflicted family. At 9 o'clock the military detachments arrived. They were composed of two divisions of infantry, two regiments of artillery, and a cavalry brigade commanded by General Saussier, Governor of Paris. At 10 o'clock the bier was placed on the funeral car, surmounted by the hat, the coat, and the sword worn by the deceased Academician. The car, which was richly decorated, was drawn by six horses. The command to present arms was given, the Garde Républicaine played Chopin's funeral march, and the entire procession slowly moved towards Notre Dame, which it reached at a quarter to twelve. The President of the Republic, who arrived at the Cathedral at twelve o'clock, was conducted to his seat by the Archbishop of Notre Dame; he was followed by the Grand Duke Constantine, Prince Nicholas of Greece, the French Cabinet Ministers, and the delegates of the Academy, diplomatic bodies, generals and their staffs. After the mass M. Poincaré, Minister of Public Instruction, took his place in a tribune arranged in front of the catafalque and pronounced a funeral oration, in which he sketched Pasteur's labours and their benefit to humanity. He laid great stress on the modesty and moral worth of this earnest and ardent worker. The body of Pasteur reposes in one of the side chapels of Notre Dame. It is stated that its abiding resting place is to be the spot in the courtyard of the Pasteur Institute where now stands the statue of Juppille, the shepherd, Pasteur's first patient, and a statue of Pasteur will replace that of Juppille. Perhaps the most touching and impressive incident in the funeral ceremony was the lowering of the national flag when the procession passed round the catafalque, before the body was removed from it. The President of the Republic stood bareheaded, and the foreign princes gave a military salute.

Pasteur's will is very simple, it runs as follows:

"This is my testament. I leave to my wife all that the law allows me. May my children never forsake the path of duty, and always cherish for their mother the tenderness she so richly merits.—L. PASTEUR. Paris, le 29 Mars, 1877. Arbois, le 25 Août, 1880."

After October 14th gratuitous patients can only be treated in their district hospital. The system of hospital circumscription will be in force. In the case of homeless persons who have found shelter in night asylums, a paper signed by the director of the night asylum must be produced. Children are admitted only into the two children's hospitals—*Enfants Malades* and *Trousseau*; the children's surgical wards of the *Tenon* Hospital, and the orthopaedic service of the asylum of the *Enfants Assistés*. Patients with specific and special diseases are treated in special hospitals, whatever may be their district—*Saint Louis*, *Broca*, *Ricord* Hospitals for cutaneous and syphilitic diseases; *Salpêtrière* for nervous diseases. *Lariboisière* and *Hôtel Dieu*, besides being district hospitals, are also special hospitals for diseases of the eye; likewise *Necker* for urinary diseases, and *Cochin* for surgical gynaecology. Patients with contagious affections are sent to *Aubervilliers* Hospital; cases of accident are to be conveyed to the nearest hospital independently of the district

in which the injured person dwells. Gratuitous advice is given every day in the out-patient department of all the important hospitals, excepting Sundays and holidays, in the morning; those which were given at the Bureau Central at the Hôtel Dieu are now suppressed.

The Association of the Gironde Medical Men gives the following advice. It is etiquette when a medical man sends a patient to a mineral water station, or to any establishment for treatment, that he should give to the said patient a letter addressed to his *confrère* who undertakes the treatment, but he should not under any circumstances give his patient directions or prescriptions for his guidance while there.

The Paris Medical Academy has named a commission, consisting of Dr. Laveran, Dr. Vallin, Dr. Lagneau, Dr. Léon Collin, Professor Proust, and Le Roy de Méricourt to investigate the means of combating malaria.

M. Ribot, Minister of the Interior, has visited the Pantin (Lubervilliers) lucifer-match manufactory. It is stated that the ministerial visit has produced an excellent impression on the workpeople. All of them declared themselves satisfied with the reforms effected. In the evening the Federal Council met. A report of the interview with the Minister was drawn up, and the delegates took their leave expressing their gratitude towards M. Ribot.

ST. PETERSBURG.

The Cholera Epidemics in Volhynia and in Siberia.—The Death of Pasteur and the Profession in Russia.—A Medical Conference on Syphilis and its Control.—The New Medical Institute for Women.—Scientific Institutions in Siberia.—The New Pirogof Museum.

Is the last letter the cholera returns from Volhynia were brought down to August 5th (17th).¹ Since that date the epidemic has reached a maximum and begun to decline, as the following figures show:

From Aug. 5th to Aug. 12th there were	2,497 cases and 944 deaths
" " 13th " 19th " "	3,362 " " 1,190 "
" " 20th " 26th " "	4,373 " " 1,698 "
" " 27th to Sept. 2nd " "	3,584 " " 1,417 "

The occurrence of considerably over 13,000 cases and 4,000 deaths in only four weeks marks the epidemic in Volhynia as the most severe outbreak of cholera in Europe during the present year. The outbreak is not confined to Volhynia. During the same four weeks there have occurred in Podolia respectively 34, 67, 35, and 18 cases, with 20, 25, 11, and 8 deaths. The contrast between the two sets of figures from two adjoining provinces is striking, but it will not be forgotten how intensely Podolia suffered during the past two years from cholera. Districts, like individuals, appear to gain a relative immunity for a time after a severe outbreak of cholera. In the last published cholera bulletin the name of the Maritime (Primorskaja) Province appears. This province borders the Pacific Ocean, and there seems little doubt that the infection was imported from China. Cases occurred in Vladivostok in the middle of July, and before the 25th of that month there were 9 cases of cholera with 7 deaths. It is now announced that from the beginning of the epidemic there to August 29th there occurred in the province 74 cases with 34 deaths, and between August 30th and September 5th, 8 cases with 4 deaths.

The loss to medical science in the death of Pasteur is as deeply felt in Russia as it will be in all other parts of the civilized world. A deputation representing the profession in St. Petersburg has already started for Paris in order to lay a wreath on the great scientist's grave, and a similar deputation has started or is about to start from Moscow with the same object.

The thirteenth conference of Zemskii Vrechi—that is, of medical officers to the zemstvos or local government corporations of the Government of Moscow—met in Moscow last week under the presidency of Professor Frisman. A more important conference, to be held in St. Petersburg in November, 1898, is one which has been summoned by the Government to consider the question of syphilis and its spread in Russia. The ravages of syphilis in this country

can scarcely be exaggerated, and it is to be hoped that the conference will do something towards diminishing the evil. The discussions at the conference will be under the following heads: (1) Syphilis in villages; (2) syphilis in towns; (3) in the army and navy; (4) the medical staff required to combat the disease; (5) the control of prostitutes.

The new Women's Medical Institute in St. Petersburg is meeting with some difficulty in obtaining a site suitable for the necessary buildings. A division of the Obukhovskii Hospital (one of the largest hospitals in the city) which had been set aside for the institute is now found to be unsatisfactory. The building committee have asked the hospital authorities to grant them a vacant space in their grounds for a new building, but the only available vacant space is required by the hospital for its own purposes. A plot of ground not far from the hospital is for sale, but the price asked—150,000 roubles—exceeds the funds at the disposal of the committee.

The opening of the Trans-Siberian Railway may be expected to prove of enormous benefit to the provinces through which it will pass—not only by the development of their material resources, but also by the introduction of the arts and sciences which invariably follow the opening up of lines of communication. In this respect Siberia is at present a long way behind, although the seeds of improvement have already been sown. For instance, Tomsk has possessed a university since 1889. In order, however, to obtain professors, the salaries offered have had to be much larger than those in any other Russian university; and, in order to attract students, the regulations of the University Code of 1884 had to be considerably relaxed. During its first year of existence the number of students in Tomsk University was 70. The medical faculty is the only one in full working order. Quite recently news came that in Blagovieshensk, on the Amur river, a bacteriological institute had been opened. At present it is mainly employed in inoculating horses against anthrax, or, as it is called in Russia, Siberian plague (*Sibirakain yazon*).

The new Pirogof Museum of Anatomy and Surgery was recently inaugurated by the laying of an inscribed stone in the Government building which is to be reconstructed for the purposes of the museum. The museum will be arranged on the lines of those of Hunter in London and of Dupuytren in Paris. So far as normal anatomy is concerned, the new collection will have a powerful rival in the fine anatomical museum in the adjoining Army Medical Academy, which was largely collected and arranged by Pirogof himself. Pirogof was for many years professor of anatomy in the Academy. A history of the chair of anatomy and of the Museum has just been published by Professor Tarenetski, the present professor of anatomy, in connection with the approaching centenary of the Academy.

CORRESPONDENCE.

RARE CASES AND THE MEDICAL SOCIETIES.

SIR,—I have just seen the excellent suggestion made in the *BRITISH MEDICAL JOURNAL* of October 8th, p. 855, and hasten to say that if my Council approves (which I feel sure it will) I shall be delighted to offer facilities for the exchange of information about important and rare cases. I should be glad to receive suggestions, but at first sight it seems to me that the most feasible plan would be to invite practitioners to send me particulars of the kind of cases they wish to study, and I would post up a daily list, with an invitation to those who know of likely cases to send a postcard giving the required information to inquirers.

A more perfect plan would depend for its success on the co-operation of the metropolitan staffs. Uniform cards could be prepared and a supply kept at each hospital; on these brief particulars of interesting cases should be written, and the cards immediately forwarded to me, and I would undertake to keep these filed in alphabetical order of disease names in such a manner that any inquirer would be able instantly to discover whether such diseases as he might wish to study could be found in London. We should, in fact, establish a kind of hospital "clearing house" of cases. If the

* All the dates mentioned are according to the old style.

hospitals will promise to co-operate I will gladly do my part.—I am, etc.,
J. Y. W. MACALISTER,
Resident Librarian, Royal Medical Chirurgical Society,
Hanover Square, Oct. 6th.

A QUESTION OF CONSCIENCE.

SIR,—On reading the letters your correspondents have been good enough to write in reply to my "question of conscience" I find myself charged with a number of theories which I most assuredly have not advanced. I have not advocated euthanasia. I do not underestimate the sacredness of human life nor the position of trust held by the physician. I would not withhold from any sick fellow creature, however worthless, one thought or consideration which might free it of pain, nor would it have occurred to me to urge the artificial abortion of an embryo though its parents were obviously syphilitic.

Only this much have I suggested, that in view of that which is plainly a higher mandate: in view of the multiple miseries of the syphilitic infant and child, and its degenerate maturity; in view more especially of the fact that not upon us, but upon these miserable little creatures from whom we avert the mercy of abortion, the consequences of our interference fall, we should in all cases in which Nature is trying to cast off a syphilitic foetus thankfully allow her to do so.

I do not consider that any onus rests upon the doctor in this matter, nor that the situation bears any relation whatsoever to a "kill or cure" adjudication. An agency more competent than he decrees that this particular embryo is unfit for survival, and enjoins its expulsion at a period when it is as yet incapable of suffering. Tolerant, with an amazing patience of other physical shortcomings, Nature's action in syphilis is the more noteworthy. She will have none of it. Embryo after embryo—if we allow her—she will abort. And if by our interference or from some other accident the foetus come to term, she curses its birth with sudden old age, shrivelling, withering, and atrophying it out of existence. Her relentlessness against it should convince us that in syphilis as in nothing else there exists a poison most inimical to human health. She makes it repellent to every sense, with its ulcerous mouth, its mutilated nose, its distorted bones, its malodour—the trail of its serpentine eruptions. She makes it raucous of voice and defective of articulation, sloughing its palate and searing its tongue. She sets contamination on the lips, whereby the infant may infect the nurse who gives him suck and the mother who kisses him.

The evils which originated it go on resulting in human pain and devotion until their forces are exhausted. Were not the path of health thus indicated by disease, to what extent should we not by now have deviated from the normal?

The fact that some victims of inherited syphilis attain a maturity which admits of their being "useful citizens" I cannot regard as subversive of my position. So long as these unfortunates are childless, the standard of human health is only temporarily lowered, but in the event of offspring the syphilitic cells in the systems of these latter will assuredly make devastating war with the cells transmitted to them by the healthy parent. Evolution must be accomplished by the garnering of vital forces, and their spontaneous generation on to ever higher planes; but if we debase these vital powers, adulterating them ever with noxious elements, what then? I have under my care a family of syphilitics who have reached maturity. The mother is robust, the father is apparently healthy; the eldest daughter is afflicted with severe congenital heart disease; the second is a neurotic without uterus or ovaries; the third is mentally deficient; the life of the fourth is embittered by the deformity of her limbs, a horrible oozing, and an unnatural unouthness; the fifth is fairly healthy; the sixth is a melancholy youth with an enlarged liver and spleen and a distressing asthma; the youngest is a great-headed, knock-kneed boy of weak intellect and vicious moral tendency.

All these unfortunates underwent mercurial treatment in their childhood, and their threatened abortion was prevented by the mercurial treatment of their mother. To me, as to them, their existence appears nothing less than a lamentable fact.

One of your correspondents says "progress consists in a

steady defiance of Nature." Could we indeed so much as heal a pin-scratch on a baby's arm were Nature not to set in motion one of her eternal laws? And if we are not to defy Nature, there is nothing left us but to co-operate with her. Shall we then, against her unmistakable decree, continue by our interference to perpetuate pain and degeneration when she would mercifully absolve the victim and the race from the further penalties of a trespass against her laws?—I am, etc.,

Watford, Oct. 6th.

LONGMORE'S GUNSHOT INJURIES.

SIR,—In the notice of the second edition of Sir Thomas Longmore's work on *Gunshot Injuries*, which appears in the BRITISH MEDICAL JOURNAL of October 6th, your reviewer speaks in terms of commendation of almost everything contained in the book, but refers to the omission of statistics of later date than those of the Franco-Prussian War of 1870-71 as constituting its great defect. He states that the statistics of the campaigns "in Egypt, Burmah, Chin Lushai, Hazara, and Waziristan, in which weapons of greater range and velocity were employed, would have been of incalculable value." If, as your readers might naturally suppose, your reviewer by this statement means to point out that these returns would have been of value because rifles of small calibre were used on these occasions, he is in error except in the case of Waziristan. In the Waziristan expedition the Lee-Metford rifle was used for the first time; but there are even now no statistics available for this campaign, and Sir Thomas Longmore's work was in the hands of the printers before it was finished. In the other campaigns mentioned the Martini-Henry rifle was employed, and we are already supplied with ample statistics as to the effects of the use of small arms of this kind.

Sir Thomas Longmore could, no doubt, have given the percentages of killed and wounded to strength in the campaigns of Egypt, Burmah, Lushai, and Hazara; but of what value this information could have been to anyone, especially when we remember the class of enemy opposed to the English forces, or how its omission from the work under review can be said to be a defect it is not easy to comprehend.—I am, etc.,

W. F. STEVENSON,

Oct. 6th. Professor of Military Surgery, Army Medical School, Netley.

* * It is satisfactory to know, on the authority of Professor Stevenson, that statistics as to gunshot injuries received in the Waziristan expedition are, even now, not available, and that their omission from the book referred to in his letter was due to no fault of its author. But surely Professor Stevenson, as a practical teacher, cannot seriously maintain that a standard work upon a subject of world wide interest is either complete or up to date which, in an important chapter on statistics, can only give figures referring to wars which occurred from twenty-five to thirty-five years ago. The experiences of the Balmaceda rebellion in Chili, in which rifles of small calibre were freely used, and also those of our own recent wars, even though the weapon used was only the Martini-Henry, are likely to be of more practical value to the student of the present day than references to the American war of the Rebellion, the Prusso-Danish war of 1864, and even of the great war of 1870. Professor Stevenson says, "we are already supplied with ample statistics as to the effects of the use of small arms." Precisely so; it was the omission of these up-to-date statistics from the book under review that suggested the criticism to which Professor Stevenson takes exception.

"THEY KNOW NOT THE MANNER OF THE GOD OF THE LAND."

SIR,—As Surgeon-Lieutenant-Colonel Chester credits me with "attributing typhoid fever to defective personal hygiene," I beg for a small space to deny the impeachment. I was not dealing with the cause—"a specific morbid poison," according to Aitken—but merely indicating one direction in which a solution of the question of susceptibility might be sought. As I said, Sir A. Home, regarding the disease as one rather of palaces than of hovels, thought it a

direction not worth following, possibly for the same reason as that named by Dr. Chester, whose argument is that because a comparatively small number of cleanly persons get typhoid fever uncleanness cannot have anything to do with producing susceptibility in the uncleanly, irrespective of dose. This kind of reasoning ignores the condition of health at the time of exposure as influencing the question of effectual or ineffectual phagocytosis; for we may safely assume that the many get the germs of disease into them, while only the few develop the disease. The statement that typhoid fever was "practically unknown" twenty or thirty years ago only means that less attention was paid to it, unless, indeed, it be the one new thing under the sun. If Dr. Chester will specify the "factors" in the case, which, he says, were non-existent twenty or thirty years ago, he will be doing a public service.—I am, etc.,

Sheffield, Sept. 26th.

F. A. DAVY, M.D.,
Surgeon-Lieutenant-Colonel, A.M.S., Retired Pay.

SIR.—In reply to the letter of Surgeon-Lieutenant-Colonel Chester in the *BRITISH MEDICAL JOURNAL*, September 25th, allow me to say that although it may be a fact that the term enteric fever was practically unknown two or three decades ago, yet it is impossible to admit that the disease, at present so called, did not then prevail among British soldiers and sailors in hot climates.

In Europe, typhoid fever was unheard of until the time of Louis, but all the evidence is against the supposition that the disease arose for the first time at the beginning of this century. Similarly, although enteric fever first appeared in the statistical returns for India in 1841, I have never heard it suggested before that the disease did not previously exist in that country. As a matter of fact, there is evidence that a fever with enteric symptoms has been a fatal disease in fleets and armies from remote times.

With regard to the increased prevalence of enteric fever in India, which has been recorded since 1870, I accept the explanation of Professor Notter,¹ that it is owing to a difference in nomenclature and to the greater number of young and recently-arrived soldiers serving in the country—and of these young and recently-arrived soldiers it may with pre-eminence be said: "They know not the manner of the God of the land."—I am, etc.,

Aberdeen, Oct. 1st.

GILBERT KIRKER, M.D.,
Staff Surgeon, R.N.

THE TITLE OF PHYSICIAN.

SIR.—If a man who holds a license to practise from a College of Physicians is not a physician, what is he? It is difficult to see on what grounds he can call himself a surgeon or an apothecary, titles which would appear to be properly reserved for those who have satisfied the examining board of a College of Surgeons or a Society of Apothecaries. And if the title of Physician is the special property of those who have passed the higher examination of the College of Physicians, surely those who have passed the higher examination of the College of Surgeons, the Fellowship, have an equally good claim to monopolise the title of Surgeon. Under these circumstances, as it has already been held by the High Court that the prefix of "Dr." is legally the prerogative of those who hold a degree in medicine, it would be a great kindness if somebody would invent a designation at once clear and inoffensive, which might be used without fear of pains and penalties by the unfortunate possessors of the M.B.C.S. and L.R.C.P., to inform the public that they are still members of the medical profession.—I am, etc.,

October 1st.

M.D., B.S. LOND.

SIR.—It seems to me that one thing at any rate still "accentuates the distinction" between the pure physician and the general practitioner, and that is the restrictions which the rules of most hospitals still impose on the professional liberty of their physicians. It appears still to be laid down in the majority of cases that the physicians are not to practise surgery, pharmacy, or midwifery in private. The surgeons, on the contrary, are allowed in their private practice an absolutely free hand in which to hold as large a bundle of

surgical and medical specialities as they can clutch. For the general practitioner of the present day, at any rate in provincial towns, appears to not infrequently endeavour to pose rather as the universal specialist, who is, moreover, prepared to perform general surgical operations, or to give opinions in consultation on medical cases as opportunity offers. He is, in addition, in some cases not by any means behindhand in emphasising the hospital rule in question when it happens to suit his purpose.

If, as you suggest, the distinction between the pure physician and the general practitioner "should no longer be accentuated as heretofore," is it unreasonable to suppose that it should follow that the old-fashioned restriction concerning the professional conduct of provincial hospital physicians should be withdrawn?

The present state of things seems to be unfair, and it is difficult to see why, at the present time, one-half of a hospital staff should be restricted and the other half left free in the performance of their private practice. I have ventured to raise this point because it seems to me to be really a practical one. As to who may "call himself a physician," or as to who is entitled to the "title of Dr.," it seems unprofitable to consider in the face of unchecked French liberty, and the occasional hardness of the present day professional conscience.—I am, etc.,

October 2nd.

ANON.

SEWER VENTILATION.

SIR.—I should like to make one or two observations in reply to the letter of Dr. Sidney Davies in your issue of September 14th. I quoted Mr. Baldwin Latham's dictum with approval, but not exactly in the sense implied by Dr. Davies in his letter.

If a sewer be not ventilated with due regard to the conditions existing within the same, then the vent or ventilation of many sewers would increase, instead of diminish the nuisance arising therefrom at certain points. Large volumes of air pass through certain sewers, and this occurs principally through those in which there is a rapid stream of sewage because the force (that is, the flow of sewage) which moves the air is continuous, and also pretty constant in its operation. In order to illustrate my points, take the following example of a supposed sewer 1,000 yards in length, and, say, 2 feet in diameter. Suppose this sewer for the first 800 yards has a great fall, and for the remaining 200 yards the gradient is much less. At the change of gradient is a manhole A, and the stream of sewage is 6 inches deep. Under such conditions sewer air will flow towards A much more quickly than it will move beyond that point, hence more sewer air will be brought to A than will be carried further down the sewer, and the excess in the amount brought down will flow out of that manhole and those immediately above it. Now suppose the manhole covers were closed, and bent pipes connected with the sewer, a similar thing will happen. The pipes in the neighbourhood of A will convey air out of the sewer, while those higher up will not act, or if they do they will probably serve as inlets of fresh air. Sectional ventilation, as suggested in my paper, in arresting the flow of sewer air will diminish the amount of fresh air gaining access to the sewer. Fresh air, in passing through a short section of sewer only, cannot, I think, be so offensive as when it flows in contact with sewage for 200 yards or 800 yards or more.

I do not assume that ventilation will render sewer air innocuous, for that possibly can only be done by burning it, but I think directing it with air as suggested above will render it somewhat less harmful, and discharging it high up in the air will further dilute and diminish the nuisance arising therefrom. With regard to the idea of vent reverse ventilation, I incline to the opinion that under some conditions the former might be the more useful, while under others the latter would be better suited to the purpose. Every sewer should be dealt with upon its merits, and that method applied which is best calculated to effect the purpose in view.—I am, etc.,

Tynesley, Sept. 21st.

OBITUARY.

SURGEON-GENERAL SIR THOMAS LONGMORE, C.B.,

Honorary Physician to the Queen.

We have been favoured with the following from Surgeon-General W. C. Maclean, C.B.

Long before this record of the life and work of the above-named distinguished military surgeon is in the hand of your readers, the fact that his life and work are ended will be widely known at home and abroad. For many years past his life was in constant peril from cardiac failure. As time went on the attacks

became more frequent and alarming, and the suffering always attending them more intense. It was a marvel to himself, his family, and professional friends, that the end, so often expected, was deferred so long.

On Sunday, September 29th, he was in the full enjoyment of the fine air of Swanage, the place above all others most congenial to him. He attended church at evening service with his wife, and slept that night with more than usual restfulness until 6.40 A.M. on the 30th, when he awoke and complained of his usual "breast pang." His brother-in-law, Colonel Moorson, hastened to call in medical aid. A few minutes before his doctor, armed with nitrite of amyl, arrived he expressed himself a little "easier." Suddenly, before there was time to use that remedy, he became cyanotic, and expired. All was over a few minutes after 7 A.M.

Thomas Longmore was born in London on October 10th, 1816. His father was a surgeon in the Royal Navy. He was educated at Merchant Taylors School. In due course became a student at Guy's Hospital. He was dresser to Mr. Bransby Cooper, assisted that surgeon in his private practice and in writing the life of Sir Astley Cooper. He arranged and catalogued the museum of that great surgeon, afterwards purchased by the Royal College of Surgeons of England. He became M.R.C.S. Eng. 1841, and F.R.C.S. 1855 and Fellow of the Royal Medical and Chirurgical Society. He was gazetted Assistant Surgeon 19th Regiment February 3rd, 1845; served with that regiment in the Ionian Islands, the West Indies and Canada, returning to England in 1851. He was gazetted Surgeon of his regiment in March, 1854 and served as Surgeon of the 19th Regiment in the Light Division of the Eastern Army from its first taking the field throughout the campaign of 1854-55, until the termination of the siege of Sebastopol; he was not absent from duty one day during the campaign. He was

present at the affair of Balaklava, battles of Alma and Inkerman, capture of Balaclava, assaults on the Redan June 18th and September 8th; and received the medal and three clasps, and the Turkish medal, and was named a Knight of the Legion of Honour. He served with the 10th Regiment in the Sepoy Mutiny war until promoted Deputy Inspector-General of Hospitals in 1858. On his return to England he was appointed P.M.O. at Colchester. In 1860 he was appointed by Lord Herbert, then War Minister, Professor of Military Surgery at the new Army Medical School, and delivered the opening address in the presence of that Minister, the General Commanding the District, and other officers of distinction.

In 1864 he represented the British Government at the

International Congress at Geneva. At this Congress the International Treaty, since known as the Convention of Geneva of August 22nd, 1864, was formally adopted, and he was a member of the Committee that settled the terms of the Convention. In 1867 he took part, by order of the Secretary for War, in the International conference of the societies for aid to wounded soldiers in time of war. In 1867 he was nominated a Companion of the Military Division of the Most Honourable Order of the Bath, and in the following year he was gazetted Honorary Surgeon to Her Majesty the Queen. In 1866 the Société Impériale de Chirurgie de Paris elected him Correspondant Étranger. In 1869 he again represented his Government at a Conference in Berlin on Aid to Sick and Wounded in War. In 1872, and again in 1873 and 1876, Surgeon-General Longmore represented the British Government at Vienna and Brussels for the settlement of international agreements relating to sick and wounded in war, and took, in a mixed committee of military and medical officers, an active part in establishing the bearer companies, and most of the

existing field hospital arrangements of the British Army. On five other occasions he represented his Government at foreign congresses, and was elected an Associé Étranger of the French Academy of Medicine and other scientific societies. In 1879 he was promoted by decree of the President of the French Republic to the rank of Officer in the Legion of Honour, the insignia of which, by Royal licence, he was permitted to wear. In 1886 he was knighted by the Queen at Osborne, and in the following year the Military Medical Services presented the fine portrait of Surgeon-General Longmore to the Army Medical Department, by George Reid, R.S.A., of Edinburgh, which adorns the anteroom of the mess-room at Netley.

I may not ask for space to give an exhaustive catalogue of his printed professional works and papers. Their mere titles take up four closely printed pages of letterpress. It must suffice to mention his *Synopsis of Cases of Heat Apoplexy*; his essay on Gunshot Wounds in Holmes's *System of Surgery*—this essay was reprinted in the United States, and formed the textbook of the surgeons of both armies in the American civil war; *Report on the Whitworth Projectiles in War*; *The Medical Officer's Ophthalmic Manual*; *Treatise on the Transport of Sick and Wounded in War*. His observations on the preliminary care necessary for accidental injuries, read at the annual assembly of St. John of Jerusalem, 1874, was the starting point of the St. John ambulance classes throughout the kingdom. He was also the author of *Antiseptic Surgery on Battle Fields*; *Life of Wiseman*, and an immense number of lectures, reports, and papers on every subject relating to military surgery.

The above will convey to the service and profession he adorned a perhaps not inadequate conception of his public life and work. Of Longmore in private life, his loyalty as a colleague, his unselfish and generous appreciation of the work of others, the noble simplicity of his character, without egotism or finesse, the warmth of his friendship, the tenderness of his heart, his sympathy with those in trouble, sorrow, need, sickness, or any other adversity, I dare not speak. While I, the last of his first colleagues in the school in which we both served, pen this poor tribute to his memory, his brother officers are committing to the narrow house all that is mortal of my late friend and colleague. I can only, from the room to which I am this day restricted, with a sad heart say, *Vale!*

A second edition of his most important work on *Gunshot Injuries* was reviewed in the *BRITISH MEDICAL JOURNAL* of October 5th. It was entirely rewritten, and, as was pointed out by the reviewer, was practically a new book.

Mr. Ernest Hart writes: I cannot omit to add my personal and official testimony to the high character, unusual ability and great services which Sir Thomas Longmore through a long and useful life rendered to his country and his department. It is unnecessary for me to speak of his high intelligence and painstaking capacity in the fulfilment of his important functions in the field, the camp, and in the lecture-room at Netley. As a teacher Longmore possessed qualities of an unusual kind; he separated clearly the essential from the accessory facts of his department of surgery, and he spared no pains to analyse all the evidence for or against the conclusions at which he arrived, and the doctrine which he taught. To the last he remained thoroughly in touch with the whole progress of military surgery, and numerous experts from foreign armies who have spoken to me of his attainments and teaching both prior to their visits to Netley and on their return, never failed to do justice to his unusual ability and great usefulness as a teacher and trainer of men. I wish in this brief note especially to emphasise one side of his work which is but little known. For the last twenty-five years Longmore has been the trusted, energetic, and public-spirited friend not only of all Netley men, but of the whole of his department. I should have felt myself much weakened and frequently perplexed in the long battle which I have waged during the whole of that time for the improved organisation and the enlarged privileges of the Army Medical Department without his constant advice, large experience, and sound judgment in the solution of all the difficulties encountered as they arose, and in the fair discussion and thorough investigation of all the grounds of opposition to the numerous reforms which we have been enabled to aid or to carry through in spite of steady official opposition. For Longmore was essentially a moderate and a fair-minded man, cognisant of all that was in the official mind and well acquainted with office difficulties and with the reluctance of military as well as high medical authorities to enter upon changes such as those which we have succeeded in bringing about, but of which some have still yet to be made.

Longmore was from first to last always young in spirit, progressive in thought, and sympathetic with reformers. A very large proportion of the articles, memoranda, and notes which appeared in the *BRITISH MEDICAL JOURNAL*, and much of the substance of the reports which I have submitted to the Parlia-

mentary Bills Committee on army medical matters, were either due to his pen or underwent revision at his hands. In the conduct of the military department of this *JOURNAL* and in all that related to the questions of military surgery and administration, the sound judgment and unbiassed criticism and fearless independence of Sir Thomas Longmore have been of constant advantage, and it would not be right that his name should pass into oblivion, or that the grave should close over him without this tribute to the helpful kindness, the unvarying sympathy, and the great ability with which he has for many years assisted in the fight for those changes in the administration of the Army Medical Department which have led, and will yet lead, to its constantly increasing efficiency and its public utility.

The profession and the public owe to Sir Thomas Longmore far more than they are ever likely to realise. Of course during his official career he was precluded by official rule from formally signing any of his contributions to our pages, but he was a man who had the courage of his opinions, and the services which he rendered to us were well known throughout the department, although not perhaps always viewed with favour by his immediate official chiefs.

SURGEON GENERAL HAMPDEN HUGH MASSY, C.B.

WE regret to have to announce the death of Surgeon-General Hampden Hugh Massy, C.B., who died at Northwood Lodge, Bournemouth, on September 27th, at the age of 75. Surgeon-General Massy entered the service in November, 1844, and took part as assistant-surgeon with the 31st Regiment in the Sutlej campaign. He was promoted surgeon and posted to the 17th Lancers, with which regiment he served in the Crimean War, taking part in the battles of Alma, Balaclava, Inkerman and Tchernaya, the affairs of Bulganak and M'Kenzie's Farm, and the siege of Sebastopol. He received the Crimean medal with four clasps, the Turkish medal, and the Medjidie (fifth class), and was recommended for promotion by Sir William Codrington and for the Legion of Honour by Lord Cardigan. He then served with the 2nd Dragoon Guards during the Indian Mutiny, was present at the siege and capture of Lucknow, the actions of Koorsie-Transagra and Burgaon, and also acted as principal medical officer to Brigadier-General Barker's column in the Oudh campaign. He received the Indian medal with clasp, was made a Companion of the Bath on June 2nd, 1860, and retired as Surgeon-General on April 1st, 1880, with the grant of the good-service pension for meritorious service.

JOHN CHARLES LANGMORE, M.B.LOND., F.R.C.S.ENG. THE death of Dr. Langmore has removed from the ranks one of the patriarchs of the profession. He was the second son of William Langmore, M.D., who formerly practised in Finsbury Square, London, and he was born in February, 1814. After his general education at St. Paul's School, he commenced his medical education at the London Hospital, and became L.S.A. in 1834 and M.S.A. in 1836. He travelled abroad, chiefly in Italy, for months as medical attendant to a young man, and subsequently studied for a time at the Paris medical schools, but was recalled by his father to take a general practice in Upper George Street, Portman Square, in 1838. He graduated as M.B.Lond. in 1842, and became F.R.C.S.ENG. in 1853. He had in the previous year (1852) removed to Oxford Terrace, Hyde Park, where he remained (with the exception of seven years, during which he resided at Sussex Gardens, Hyde Park) until 1889, when his son, John Wroford Langmore, M.D. Lond., who had joined him in partnership, died. He then retired to Shepherd's Bush Green, where he died, September 29th, 1895. He had practically retired a couple of years previously, on account of ill health. He suffered in 1889 most seriously from embolism, but afterwards recovered to some extent. Of late years he had had repeated attacks of influenza; the last, which began on September 11th, eventually proved fatal, notwithstanding the careful attention of Dr. Campbell Pope and Mr. Swinford Edwards. Dr. Langmore was President of the Harveian Society of London in 1865; and when the Paddington Medical Book Society was founded in 1838, he was elected the first Honorary Secretary, and continued to hold the post until 1880, a period of fifty-one years.

He was even then the sole survivor of the twelve original members. He was endowed both by nature and education for success in practice; he was a gentleman of refined and cultured tastes; and he earned the respect and affection of a wide circle of patients and friends. Although many of these predeceased him, others remain to whom his death has caused deep and sincere sorrow.

W. H. BELLOT, F.R.C.S., M.D.

W. H. BELLOT died at Leamington on September 24th, aged 64. He was born at Manchester in 1811, and educated at the Grammar School. Afterwards he was apprenticed to and became the pupil of his uncle, Dr. Joseph Bellot of Stockport. He attended the Manchester Infirmary, and then went to London and Paris to pursue his studies. On returning to this country he became a partner with his uncle, whom he ultimately succeeded at Stockport. In 1852 he was elected an honorary Fellow of the Royal College of Surgeons of England, and in 1860 took the degree of M.D. at Erlangen. He published an essay on Nélaton's lecture on Mr. Joseph Jordan's autoplasmic treatment of ununited fracture. He retired from practice in 1894, and since then has resided at Leamington.

His elder brother, Mr. Thomas Bellot, F.R.C.S., translated a part of Galen, and also wrote a treatise on the *Sanskrit Derivation of English Words*, and he was one of the earlier workers in the domain of scientific philology. Whilst in the East he made a valuable collection of Chinese books and ancient bronzes. These he directed should become the property of the Manchester Free Library at the death of his brother, but many of the books were transferred at once, and now constitute the "Bellot Collection."

FRANK H. HODGES, M.R.C.S. ENG., F.R.C.S. EDIN.

THE late Mr. Frank Hodges, of Leicester, was a student first at the London Hospital, and subsequently at Edinburgh, where he was appointed eventually Resident Physician at the Royal Infirmary. He afterwards held the office of Resident Surgeon to the Birmingham and Midland Eye Hospital, and early determined to devote himself to ophthalmic practice. Before settling down to this speciality he wisely sought to obtain a wider experience in general surgery, and held in succession the offices of House-Surgeon to the York County Hospital and to the Leicester Infirmary. He was finally elected Ophthalmic Surgeon to the infirmary, and obtained a reputation in that department, which was well earned by the ardour and diligence which he brought to its study. He was an excellent operator, and was untiring in his devotion not only to private practice, but also to his hospital duties.

An intimate friend writes of him: "His character was truly noble and unselfish. He had a stern up-hill fight, and was beset by many private troubles; but he was uniformly sincere to his high professional ideal, and all who knew him are familiar with his quiet courage in facing difficulties, and with his entire devotion to the conscientious discharge of all his duties. Among his many excellent characteristics was a manly love of cricket, in which he used to excel; but a noteworthy trait in his character was his passion—an hereditary one—for music of a high class. His moral and intellectual nature was in harmony with these tastes."

It is sad to record that a career of so much promise should have been terminated in so sad a manner. He broke down under the strain of overwork, and his condition became critical last June. An attack of the nature of sun apoplexy was followed by great prostration, for which he sought repose first at Filey and afterwards in Lincolnshire. He returned to work, but was seized with a return of symptoms which indicated cerebral disorder, and he ended his life by his own act on September 7th.

The esteem in which he was held by his professional brethren was shown by the large attendance at his funeral.

We regret to announce the death of Dr. EDWARD THOMAS TYLECOTE, which occurred on September 16th, at Great Haywood, after a trying illness. Dr. Tylecote was born at Great Haywood, graduated at Aberdeen in 1860, and then returned to Great Haywood where he succeeded to his father's practice and passed the whole of his life. Dr. Tylecote took

an active interest in all local matters of the district. For many years he acted as people's warden of the parish church of Great Haywood and took a special interest in the management of the schools, and he was elected a member of the first parish council for his parish. Dr. Tylecote leaves a widow and one daughter.

The sudden death is reported of Dr. R. B. MORLEY, of Chapel-Alleston, near Leeds, on October 3rd. He had gone on a bicycle to visit a patient, and whilst in the act of examining fell back and expired in a few moments. The patient died the next day, her death, it is believed, having been accelerated by the shock. Dr. Morley, who was 43 years of age, was educated at the Yorkshire College, Leeds; he was a member of the British Medical Association and of the Yorkshire Branch.

The death is announced of Dr. LARREY, member of the Institute and of the Academy of Medicine, Paris. Born in Paris in 1808, Baron Felix Hippolyte Larrey was the son of the famous surgeon of Napoleon I. He first entered the sanitary service of the army. He obtained the doctor's degree in Paris in 1832, after which he entered the Northern Division of the army, and was present as a high official in the Ambulance Corps at the siege of Antwerp, and then was appointed Chevalier of the Order of Leopold. In 1841 he became Professor of Pathological Surgery at the Val-de-Grâce Hospital. He was appointed in 1858 Inspector of the Army Sanitary Service, and received the title of Chirurgien Ordinaire du Chef de l'Etat. As Surgeon in Chief in the army of Italy in 1859, he distinguished himself in that campaign by his devotion and courage. At Solferino his horse was killed under him. Dr. Larrey became Chevalier of the Legion of Honour in 1843, Officer in 1851, Commander in 1859, and, upon his retirement in 1871, Grand Officer. In 1876 he tried for a seat at the Chamber but he was not successful, although in the following year he was elected at Bagnères by 12,000 votes. He did not again offer himself, however, in 1884. Baron Larrey published a great number of works on military surgery.

By the death of Dr. FRANCESCO VALLARDI, of Milan, Italy has lost its principal medical publisher. He was himself a member of the medical profession, having taken his degree in 1833. He was the son of a publisher, and was born at Milan in 1809, and after a short experience of medical practice he determined to go into the publishing business. To his liberality and enterprise are largely due the development of rational medicine and the diffusion of the scientific spirit in Italy during the last thirty years. He gave his countrymen the best work of other countries in the form of translations of the writings of Niemeyer, Erichsen, Holmes, Leisak, Hebra, and others; and he encouraged and helped Italian investigators to give their work to the world. In a recent number of the *Gazzetta degli Ospedali*, Professor Rizzozzo of Turin bears eloquent witness to the enlightened spirit in which Vallardi conducted his business and to the integrity and elevation of his character.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently passed away are: Dr. Slawczynski, a well-known practitioner of Berlin, aged 74; Dr. Valentini, a distinguished medical officer of the German army, and since 1834 President of the Italian Society of Berlin, aged 88; Dr. Gustav Amburger of St. Petersburg, author of numerous contributions to medical literature, aged 55; Dr. Marcus Nohlbeck, Chief Physician of the Michael Hospital at Tunis, aged 57; Dr. A. Tebaldi, Chief of the Psychiatric Clinic of the University of Padua; Dr. J. F. de Macedo Pinto, Emeritus Professor in the Medical Faculty of the University of Coimbra, aged 80; Dr. A. de Carvalho, Professor of Anatomy in the Medical Faculty of Bahia; Dr. Jambon, Chief surgeon to the Hospital of Macon; Dr. W. Bode, to whom the development of Nauheim as a health resort was largely due; Dr. Hertwig, who took a leading part in organising the municipal abattoir of Berlin; and Dr. F. Berghammer, Surgeon-Dentist to the King of Bavaria, formerly a medical officer in the Bavarian army. He had seen much service in the field during the American civil war and in the campaign of 1866.

MEDICO-LEGAL AND MEDICO-ETHICAL.

PROFESSIONAL ADVERTISING.

Under this title we published in the BRITISH MEDICAL JOURNAL of September 21st, page 126, a letter from a correspondent, who called attention to an announcement in the *Daily Telegraph* of the return of a certain physician to his London residence. He pointed out that, according to a standing statement in that paper that "all society and fashionable paragraphs will be charged at a minimum rate of 1 guinea for two lines, each succeeding line 10s. 6d. additional." Other correspondents now send us the following announcement, cut from the *Daily Telegraph* of October 1st, 1895. He states that similar announcements have appeared in former years; if so the practice is one which ought to be discontinued.

"Dr. and Mrs. Hugh Fenton have returned to 27, George Street, Hanover Square, from Lochmaddy, N.B."

Other correspondents send us a cutting from the *Daily Telegraph*, making a similar announcement with regard to Dr. Robson Roose:

"Dr. Robson Roose has returned to Hill Street after a visit to South Africa."

A MEDICAL LIBEL ACTION.

AT the Victoria Courts, Birmingham, on September 14th, Mr. Hinkinsnap, acting as Under Sheriff for the county of Stafford, sat with a jury to assess damages in an action for libel, which the defendant had allowed to go by default at the assizes.

The case for the plaintiff, Dr. H. Shore, of Walsall, was that in a letter which was written by the defendant to a local newspaper he had been libelled. The letter was written in reference to an inquest which had been held on the body of Caroline Johnson, aged 78, the mother of the defendant, owing to Dr. Shore's refusal to grant a certificate. After hearing the evidence the coroner's jury had returned a verdict of "Death from natural causes." Mr. B. S. Johnson, in his letter, complained that "he thought it a cruel injustice to have an inquest forced upon him when such a thing was, in his opinion, entirely unnecessary." He further made the following statement, that "at the inquest Dr. Shore was asked by the coroner what the deceased was supposed to be suffering from when he was called in, to which the doctor made the startling reply, 'Fracture of the hip and other injuries.'"

"Now this is a most wilful untruth, as neither my sister or I ever expected such a thing. The coroner then asked him what was his opinion as to the cause of death, when he replied, 'The mental changes consequent upon old age accelerated by erysipelas.' Now this I find to be absurd. He further remarked that she might possibly have lived another fortnight if erysipelas had not set in, but not longer. Then I ask why I should be put to the outrageous ceremony of an inquest with its attendant and false reports in the evening papers?"

There was a further passage in the letter which the editor struck out, imputing that "the inquest fee of £1 is proved too great a temptation for him (Dr. Shore). It was contended that the defendant by his letter imputed to the plaintiff that he had committed wilful and corrupt perjury at the inquest, and that he was ignorant and unfit to perform the duties of a medical practitioner; also that he refused to give a certificate of death in order that he might obtain the inquest fee. Damages to the extent of £100 were claimed. Judgment went by default, and the case was remitted to the sheriff for the purpose of assessing the damages. At this court the defendant attempted to reopen the case, but was promptly checked by the learned judge, who refused to allow him to speak on other than the question of damages. It was held that the plaintiff need not prove any specific damage, but that any aspersion of the kind indicated upon a professional man was a subject for damages.

The defendant spoke on his own behalf in mitigation of damages, and stated that he would have settled the matter out of court, but that the prosecution insisted upon a publication of the apology, and this he would not consent to allow.

The Under Sheriff summed up to the effect that a libel of this nature upon a medical man might be the subject of heavy damages, but that it would not do for the jury to estimate these damages at a larger amount than the defendant could pay. He pointed out that the defendant, by persisting in his assertion that the libel was true after he had allowed judgment to go against him by default, had made the matter more serious, and the jury might, if they thought fit, take this into account.

The jury returned the damage at £50.

The remark of the Under Sheriff upon hearing this verdict that the defendant was a "very lucky man" will be echoed by all the members of the profession. It is difficult enough for medical men to defend their professional honour against the attacks of unprincipled persons, as to do this entails expenditure of time as well as money, but it will be doubly difficult when a jury estimates the damage, admittedly sustained (the defendant in this case having attempted no defence) at such a low figure. Dr. Shore is to be congratulated by all of us on his pluck in bringing this case forward, but we must also sympathise with him on the verdict. We notice that apparently Dr. Shore was not a member of any defence union.

MEDICAL ETHICS.

A. writes: A goes away for a holiday leaving a *locum tenens*. A club patient, four miles off, sends at 7 P.M. asking doctor to go. Patient has been under treatment some time. A's *locum tenens* cannot go, then gives messenger medicine, and tells him to send or come in the morning if the patient is not better. The messenger conveys a garbled message, tells friends that if they do not send doctor will come. No message being sent in the morning, A's *locum tenens* does not go. At night B. is called in without further communication with A's *locum tenens*. B. takes charge of case without communicating with A's *locum tenens*. B. receives a letter from patient's friends dispensing with his services. A. returns, proposes to resume charge of case. The patient and friends are quite satisfied that he should. He writes to B. thanking him for

his taking charge of the case. B. replies to the effect that he has asked the patient and friends, and as they are anxious that he should attend he considers he is entitled to do so. Ought B. not to have communicated with A's *locum tenens*, and then, on finding that his failure to attend was due to a misunderstanding, ought he not to have left the case to A's *locum tenens*? Ought B. not in common fairness to have resigned the case to A. on his return?

. The above incident affords another instance of the imprudence of entrusting a more or less important message verbally to an unlettered messenger. Assuming, however, that the statement is a fair version of the facts, there can be no doubt that, medico-ethically, it devolved upon B. to communicate with A's *locum tenens* in relation to his (B.'s) attendance on the patient in question. Moreover, on receiving A's explanatory note he (B.) should have at once have retired from the case, and his omission to do so constitutes, in our opinion, a grave neglect of ethical duty, and of the moral precept to do unto others as he himself would wish to be done by.

CONSULTANTS AND THE WIVES OF MEDICAL MEN.

A MEMBER.—We would refer our correspondent to the explicit replies published in the BRITISH MEDICAL JOURNAL, p. 126 and p. 127, under the respective headings of "Professional Services to Doctors and Wives," and "Consultant and the Wives of Medical Men," and if he fails to comprehend their true import, containing as they do a specific answer to the question twice submitted, we reluctantly shrink from making a third attempt to convey in another form of words our simple and intelligible reply.

With reference to our correspondent's further question relative to the title of physician and "Dr.," the subject has been so fully discussed, month after month, in our columns, that we are constrained to refer him to the registrar of his college for a definite exposition on the special point in dispute.

A COMPLICATED CASE.

B. writes: B., a general practitioner, consulted by E., agrees to meet in consultation G., who formerly attended E. G. is a consulting surgeon. G. writes to B., making an appointment, saying under no circumstances will he see the patient except with B., as he considers B. B.'s patient. A line of treatment is agreed upon and is carried out for eighteen months by B. During this time B. had occasion to remonstrate with G. for seeing the patient, prescribing, and not acquainting B. Patient E. becomes tired of the restraint carried out by B. and objects to see him; then G., without any communication with B., supersedes him by another medical man, although B. has merely done what was agreed on. Patient's husband acknowledges B.'s services, and says G. has acted thus so that B. may not be insulted by the patient, namely, a mental case. B. remonstrates with G., but can get no satisfactory explanation. How can a consulting surgeon to a special hospital explain his action in a purely medical case?

. That B. had an unquestionable right to decline the continued attendance of B. there can be no doubt; but even if sanctioned by the husband it would not justify the alleged course of action adopted by the consultant, whose procedure in the case would appear to have been more or less irregular and unethical. Need we remind B. that the fact of G. being a surgeon-consultant to a special hospital would not, however otherwise uncommendable, preclude him, if legally qualified, from attending a medical case?

ADVERTISEMENTS BY DENTISTS.

OBSERVER.—The advertisement of Mr. O'Duffy in the lay press, to which our attention has been called, is certainly in bad taste, and contrary to the unwritten etiquette of the medical profession. The Royal College of Surgeons in Ireland, who require their dental licentiates to sign an obligation not to advertise, would no doubt communicate their views to the perpetrator of this advertisement, if the Secretary were officially informed of the infringement of their laws.

THE TITLE OF DENTIST.

E. W. W.—The 3rd Clause in the Dentists Act is as follows: "A person shall not be entitled to take or use the name or title of 'dentist' (either alone or in combination with any other word or words), or of 'dental practitioner,' or any name, title, addition, or description implying that he is registered under this Act, or that he is a person specially qualified to practise dentistry, unless he is registered under this Act. Any person who, not being registered under this Act, takes or uses any such name, title, addition, or description as aforesaid, shall be liable on summary conviction to a fine not exceeding twenty pounds." The dental qualifications are granted after examination by the Royal Colleges of Surgeons and not by schools; the latter are for educational purposes only.

TOUTING SOCIETIES AND PERSONAL ADVERTISEMENT.

DR. ARTHUR C. SHAW-MACKENZIE (Fulham) writes: My attention has been drawn to the remarks in the BRITISH MEDICAL JOURNAL, Sept. 28th, on "Touting Societies and Personal Advertisement." I desire to say that several weeks ago before your notice appeared, the undesirability of such a label had been pointed out to me, and I determined to withdraw all such as I could and to issue no more. As regards the clubs themselves, I can hardly think you realise the impossibility of a young man competing in a district like this without one. I have been in Waltham Green eight years, and it is only in the last few months, when I found my patients leaving me to join other men's clubs that I felt compelled to join in self-protection. No fewer than 140 medical men belong to this club in West London, and 13 or 14 belong to another big club supported by the clergy of this district, and there are numerous others. In

issuing the labels to the society, which were on the lines of similar labels and rules to members of other clubs, there was, I considered, no particular harm or injury to neighbouring medical men. When periodical societies or sick clubs encourage a family to join for 3d. a week, which includes husband and wife, and all the children under 14 years, and payments of midwifery are encouraged by 2s. 6d. monthly payments in advance, and no restraints put on touting, it is extremely difficult for an individual medical man to hold his own fairly against his competitors.

I venture to hope your readers will think that I have been the victim of circumstances rather than have wilfully transgressed professional regularity.

* We are pleased to learn that our correspondent has withdrawn the objectionable labels, and trust his example will be followed by other practitioners whose labels have likewise been forwarded to us, and are every whit as bad. Debasing as it is from a professional point of view to have anything to do with "touting" societies, it is still more disgraceful for a practitioner to endeavour to advertise himself broadcast by means of labels printed under the cover of their names. Our correspondent complains bitterly of the competition young practitioners have to contend against, and of the laxity in professional ethics displayed by many of his professional neighbours. But two wrongs do not make a right, and it is precisely this ethical laxity that renders the struggle for professional existence so keen, and in many cases so undignified and unworthy of an honourable profession.

THE POLICE AND CASES OF ATTEMPTED SUICIDE.

THE house surgeon of a provincial infirmary writes that he had, a few days ago, a case of attempted suicide—cut throat—brought in from a neighbouring district; that he informed the county police, and requested them to make the customary provision for watching the case, but that they replied that they had not arrested the woman, and told they did so they were not responsible, and consequently they refused to watch her.

* We have referred the matter to Mr. Nelson Hardy, who replies as follows: They were quite right, and no legal dictum is required to show that until a person is formally charged with an offence the police have no power to control his or her movements. We do not suppose our correspondent is desirous of becoming the accuser of his patient, nor do we think it desirable that he should do so; and if her relatives take no step in the matter, it is not the duty of the hospital authorities to act. If the borough police act differently—as our correspondent informs us they do—they act *ultra vires*.

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF CAMBRIDGE.

EXAMINATION IN SANITARY SCIENCE.—The following candidates have satisfied the examiners in both parts of the Examination:

B. F. Carac, C. Chida, T. Dunlop, J. Gallely, J. J. Gorham, C. R. M. Green, P. G. Griffith, G. W. Hayward, E. Hill, Kate Marion Hunter, A. Jervis, D. C. Muir, G. Newman, W. J. Potts, J. T. Frangnelli, M. A. M. M. M. M.

BOTANICAL DEPARTMENT.—The late Professor C. C. Babington has bequeathed his valuable collection of plants and his botanical library to the University.

UNIVERSITY OF DURHAM.

AT a Convocation held at Durham on September 25th, the following degrees in Medicine were conferred by the Warden, Dean Kitchen:

M.D. (ad eundem).—W. Ewart, Queen's College, Cambridge.
M.D. (Dissertation).—B. Duke, E. Duke, R. Hartley, G. H. Hetherington, J. E. Richards, H. A. Smith, W. Hykes, W. F. Thomas, W. P. Turner, J. F. Woods.

M.D. J. H. Baker, J. Brathwaite, T. Beattie, W. A. Dow, J. W. H. Eyre, W. E. Harker, R. L. Meade-King, G. Metcalfe, F. B. Rutter, F. Spett, I. C. Thorne Thorne.

M.B. G. Beven, W. Turnbull, N. C. Gwynn, J. J. Grace, L. G. Fraser, H. I. Hatch, J. R. Adamson, A. Baker, S. Barker, W. S. Carpenter, H. Clayton, R. C. de Lacey, W. G. Fell, L. Fothergill, H. H. Gentry, G. W. Harbottle, A. H. Hobbs, J. S. Moxford, C. N. O'Brien, W. H. Kowell, W. J. Rowland, F. R. Sutton, C. Stewart, F. S. Walker.

B.A. J. R. Adamson, A. Baker, S. Barker, G. Beven, H. Clibbott, R. C. de Lacey, L. G. Fraser, W. G. Fell, N. C. Gwynn, G. W. Harbottle, H. I. Hatch, A. H. Hobbs, E. H. Kendall, J. S. Manford, C. Meaden, W. H. Kowell, F. R. Sutton, C. Stewart, W. Turnbull, F. S. Walker, J. J. Grace.

B.M. G. Beven.

Among a number taking Mus. Bac. was Miss M. U. Arkwright, of Newbury, who is the first lady to take a degree in music at Durham.

ROYAL UNIVERSITY OF IRELAND.

FINAL EXAMINATION IN MEDICINE, AUTUMN, 1904.—The Examiners have recommended that the following candidates be adjudged to have passed the above-mentioned examination:

J. W. Bannister, Queen's College, Cork; W. Barkley, Queen's College, Belfast; P. J. Carroll, Queen's College, Cork; Emily M. Crooks,

Queen's College, Belfast; D. J. Farnan, University College, Dublin; A. J. Frost, University College, Dublin; C. E. Geraghty, University College, Dublin; G. Graham, Queen's College, Galway; R. J. Hackett, University College, Dublin; T. Hurst, Queen's College, Belfast; R. Kennedy, University College, Dublin; Kathleen F. Lynn, Royal College of Science, Dublin; R. McCarrison, Queen's College, Belfast; T. J. B. McDonagh, University College, Dublin; P. G. Moran, University College, Dublin; M. J. Mahony, University College, Dublin; J. J. Rabb, Queen's College, Belfast; M. L. Rowan, B.A., Queen's College, Belfast; F. Ryan, University College, Dublin; R. F. Shephard, Queen's College, Cork; J. E. Simpson, Queen's College, Belfast; P. Stark, Queen's College, Cork; W. Starke, University College, Dublin; J. J. Walsh, University College, Dublin; W. Watson, Queen's College, Belfast.

The following candidates may present themselves for the Further Examination for Honours in the subjects set opposite their names. Where more than one subject is mentioned the candidate will be allowed to present himself in all:

W. J. Bannister, Experimental Physics; P. J. Carroll, Zoology and Experimental Physics; D. J. Farnan, Botany, Zoology, Chemistry, Experimental Physics; A. J. Frost, Experimental Physics; C. E. Geraghty, Chemistry; R. J. Hackett, Experimental Physics; R. McCarrison, Experimental Physics; T. J. B. McDonagh, B.A., Zoology, Chemistry, and Experimental Physics; M. J. Mahony, Zoology; M. L. Rowan, B.A., Botany, Zoology, Experimental Physics; F. Ryan, Chemistry and Experimental Physics; R. F. Shephard, Botany and Zoology; J. E. Simpson, Zoology and Experimental Physics; W. Starke, Botany, Zoology, Chemistry, Experimental Physics; J. J. Walsh, Zoology, Chemistry.

SECOND EXAMINATION IN MEDICINE, AUTUMN, 1904.—The Examiners have recommended that the following candidates be adjudged to have passed the above-mentioned examination:

Upper Pass.—D. Brown, Queen's College, Belfast; R. A. L. Graham, Queen's College, Belfast; B. Hanlon, Queen's College, Cork; G. Jefferson, Queen's College, Belfast; G. M. Keating, Catholic University School of Medicine; D. McCay, Queen's College, Cork; A. B. McMaster, Queen's College, Belfast.

Pass.—W. R. Bostly, Queen's College, Belfast; J. Brangan, Queen's College, Belfast, and Catholic University School of Medicine; P. J. Burke, Catholic University School of Medicine; A. W. Crawford, Queen's College, Belfast; J. M. Dunne, Catholic University School of Medicine; T. P. Flynn, Queen's College, Cork; W. Hartnett, Queen's College, Cork; G. H. Henry, B.A., Queen's College, Belfast; E. Heskin, Queen's College, Cork; T. Kennedy, Queen's College, Belfast; R. Kerr, Queen's College, Belfast; T. Magner, Queen's College, Cork; J. Martin, Queen's College, Belfast; L. T. Moore, Queen's College, Cork, and Catholic University School of Medicine; P. J. Moran, Queen's College, Belfast; J. Murray, Catholic University School of Medicine; W. Nicholson, Queen's College, Galway; W. Paisley, Queen's College, Galway; F. S. Scott, Queen's College, Galway.

THIRD EXAMINATION IN MEDICINE, AUTUMN, 1904.—The Examiners have recommended that the following candidates be adjudged to have passed the above-mentioned examination:

Upper Pass.—J. G. Corry, Queen's College, Galway; G. A. Hinks, Queen's College, Belfast; W. G. Jordan, Catholic University School of Medicine and Queen's College, Belfast; O. E. McCutcheon, B.A., Queen's College, Belfast; C. E. McDade, B.A., Queen's College, Belfast; W. H. W. Mowbray, Queen's College, Belfast; H. J. Monypenny, Queen's College, Belfast; R. Moore, M.A., R.E., University College, London; L. Robinson, Catholic University School of Medicine; J. H. Stewart, Queen's College, Belfast.

Candidates marked (*) may present themselves for the Further Examination for Honours.

Pass.—A. Birmingham, Catholic University School of Medicine; J. H. Davis, Queen's College, Belfast; J. Harvey, Queen's College, Belfast; B. P. Healy, B.A., Catholic University School of Medicine; J. Johnston, Queen's College, Belfast; J. F. Keenan, B.A., Queen's College, Galway; T. A. Kelleher, Queen's College, Cork; J. J. Kinsella, Catholic University School of Medicine; J. M. McCarthy, Queen's College, Cork; J. H. McCann, Queen's College, Belfast; L. McDonald, Catholic University School of Medicine; F. C. McKee, Queen's College, Belfast; R. R. McLean, Queen's College, Belfast; J. J. A. G. Murphy, Queen's College, Belfast; G. J. Murphy, Queen's College, Belfast; C. J. Moore, Catholic University School of Medicine; J. P. J. Murphy, Queen's College, Cork; R. J. Murray, Catholic University School of Medicine; D. S. Robinson, Queen's College, Belfast; W. S. Shaw, Queen's College, Cork; J. Shinkwin, Queen's College, Cork; H. W. G. Stewart, Queen's College, Belfast; W. J. Wilson, Queen's College, Belfast.

THE UNIVERSITY COLLEGE OF SOUTH WALES.

AT the half-yearly meeting of the Court of Governors of the University College of South Wales and Monmouthshire, on October 25th, it was announced that the Treasury were prepared to insert in next year's estimates a grant of £20,000 to the Welsh University provided that a similar amount were collected locally within a given period of years. The Dymorp Company, which has already endowed the University College of South Wales with a professorship of engineering and with several scholarships has now offered £20,000. It was resolved locally within twelve months. The Governors resolved unanimously that an appeal to the public for £20,000 should be organised and local committees appointed to further this object. It was reported that the number of students attending the College in 1904 had been 300, of which number 100 were from South Wales and Monmouthshire. It is evident, therefore, that the College is meeting a real local demand and it cannot be doubted that the endowment fund now asked for will be raised without delay. The financial position of the College is already fairly good, though the deficit this year was £100. A sum of £10,000 is to be received shortly from the Cardiff Corporation, and when this has been paid over the financial position of the College will be far more satisfactory.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

THE following gentlemen passed the Second Examination of the Board in the subjects indicated.

Monday, October 7th.

Anatomy only.—A. H. Heywood, student of Yorkshire College, Leeds; G. H. Irvine, F. A. Coster, E. A. Johnson, and J. W. Wallace, of University College, Bristol; S. Bentley, of Firth College, Sheffield; A. M. Dodd and A. Johnson, of University College, Liverpool; E. E. Wray and W. T. Jackson, of Owens College, Manchester; J. H. Mort, of Cambridge University and Owens College, Manchester; G. O. P. Kelly, of Queen's Medical College, Dublin; E. H. Musgrove, of University College of South Wales, Cardiff; J. I. Harkin, of Queen's College, Cork; and W. A. B. Jones, of University College, London.

Anatomy and Physiology.—C. F. Watson, H. S. Turner, R. J. Pritchard, and E. C. Daston, of Guy's Hospital; E. L. Roe, of Cambridge University and Guy's Hospital; H. H. Elworthy, G. S. Gato, of Westminster Hospital; J. M. Edwards, of Charing Cross Hospital and Mr. Cooke's School of Anatomy and Physiology; H. S. Koch, of King's College, London; C. E. Evans, of University College, London; S. Hay, of Cambridge University and St. Bartholomew's Hospital; W. I. Bradley, of McGill College, Montreal, Canada; G. Young, of London Hospital and Trinity College, Dublin; A. R. Kay, J. L. Morris, and F. G. Richards, of St. Bartholomew's Hospital.

Anatomy only.—J. E. Francis and J. W. Chees, of University College, London.

Physiology only.—G. B. Nicholson, of Cambridge University and St. Bartholomew's Hospital, and E. Fryer, of Guy's Hospital and Mr. Cooke's School of Anatomy and Physiology.

Sixteen gentlemen were referred in both subjects, 4 in Anatomy only, and 1 in Physiology only.

Tuesday, October 8th.

Anatomy and Physiology.—C. F. Watson, H. S. Turner, R. J. Pritchard, and E. C. Daston, of Guy's Hospital; E. L. Roe, of Cambridge University and Guy's Hospital; H. H. Elworthy, G. S. Gato, of Westminster Hospital; J. M. Edwards, of Charing Cross Hospital and Mr. Cooke's School of Anatomy and Physiology; H. S. Koch, of King's College, London; C. E. Evans, of University College, London; S. Hay, of Cambridge University and St. Bartholomew's Hospital; W. I. Bradley, of McGill College, Montreal, Canada; G. Young, of London Hospital and Trinity College, Dublin; A. R. Kay, J. L. Morris, and F. G. Richards, of St. Bartholomew's Hospital.

Anatomy only.—J. E. Francis and J. W. Chees, of University College, London.

Physiology only.—G. B. Nicholson, of Cambridge University and St. Bartholomew's Hospital, and E. Fryer, of Guy's Hospital and Mr. Cooke's School of Anatomy and Physiology.

Sixteen gentlemen were referred in both subjects, 4 in Anatomy, and 2 in Physiology only.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

RESULTS OF EXAMINATIONS.—The following analyses of the results of the examinations held by the Royal College of Surgeons during the past two years contains some interesting facts. The enormous proportion of failures in Chemistry at the Conjoint Board's First Examination is particularly worthy of note, and appears to indicate some very serious defect in the present method of educating students in this subject. The general run of boys' schools, where the teaching in science is often most defective. It cannot be said either that the result of the Second Examination under the five years' regulations is very satisfactory. Failures amounting to 45 per cent. must be due to defective teaching or imperfect examinations.

First Conjoint (Five Years' Regulations).

	Number of Candidates.	Referred.	Percentage of Passes.
1893-4.			
Chemistry	497	210	57 per cent.
Pharmacy	147	55	70 " "
Biology	448	159	67 " "
Botany	467	91	80 " "
1894-5.			
Chemistry	510	210	59 " "
Pharmacy	228	45	80 " "
Biology	488	161	67 " "
Botany	487	84	82 " "

Second Conjoint (Five Years' Regulations).

	Number of Candidates.	Referred.	Percentage of Passes.
1893-4.	59	30	49 per cent.
1894-5.	288	101	65 " "

Third Conjoint (Four Years' Regulations).

	Number of Candidates.	Referred.	Percentage of Passes.
1893-4.			
Medicine	800	270	66 per cent.
Surgery	843	358	57 " "
Midwifery	849	281	67 " "
1894-5.			
Medicine	805	284	65 " "
Surgery	880	304	66 " "
Midwifery	894	295	67 " "

First Fellowship.

	Number of Candidates.	Referred.	Percentage of Passes.
1893-4.	160	86	46 per cent.
1894-5.	171	100	41 " "

Final Fellowship.

	Number of Candidates.	Referred.	Percentage of Passes.
1893-4.	160	86	46 per cent.
1894-5.	171	100	41 " "

Dental Surgery.

	Number of Candidates.	Referred.	Percentage of Passes.

SOCIETY OF APOTHECARIES OF LONDON.

PASS LIST.—The following candidates passed in **Surgery**.—F. Butcher, Royal Free Hospital; A. E. Garraw, McGill University; R. Jones, St. Mary's Hospital; C. F. Preston, Manchester; C. A. K. Renshaw, Cambridge and Manchester.

Medicine, Forensic Medicine, and Toxicology.—L. M. Broton, St. Thomas's Hospital; F. Butcher, Royal Free Hospital; J. Garraw, Manchester; A. E. Garraw, McGill University; J. S. G. Jones, London Hospital; E. T. V. van Hempe, Royal Free Hospital.

Medicine and Forensic Medicine.—E. A. Jones, London Hospital; J. S. G. Jones, Dublin.

Medicine.—E. H. Sims, Leeds and Glasgow; J. S. G. Jones, Manchester; M. K. B. Hoist, Royal Free Hospital; T. W. Jones, Toronto.

Midwifery.—R. Goulden, Manchester; P. H. Jones, University College.

To Messrs. Abbott, Broton, Butcher, Jones, Jones, Garrow, and and since was granted the diploma of the Society.

PRIMARY EXAMINATION, PART I.—The following candidates passed in: **Chemistry.**—R. Brookes, Westminster; C. H. Thomas, London Hospital; A. H. Wilson, Birmingham.

Material Medica and Pharmacy.—F. E. T. Jones, Royal Free Hospital; E. C. Scarlett, Royal Free Hospital.

Material Medica.—H. Greenwood, London Hospital.

PRIMARY EXAMINATION, PART II.—The following candidates passed in:

Anatomy and Physiology.—J. W. Chees, University College; J. D. R. Cogan, Guy's Hospital; G. S. Goulden, Manchester and Edinburgh;

E. Fryer, Guy's Hospital; G. E. Hogan, St. Bartholomew's Hospital;

D. V. Lowndes, London Hospital; E. A. O. Mansell, St. Bartholomew's Hospital; H. R. Miller, Guy's Hospital; C. R. White, Edinburgh.

Anatomy.—S. R. Bhagani, King's College; H. Charles, Middlesex Hospital; J. C. E. Dunn, St. Bartholomew's Hospital; G. W. Dutton, Middlesex Hospital; J. Ellis, Edinburgh; R. Hogan, London Hospital; A. R. Hoare, St. Thomas's Hospital; R. O. Jones, Guy's Hospital; E. F. Lampert, Royal Free Hospital; H. W. B. Walling, Guy's Hospital.

Physiology.—F. G. Aldrich, Charing Cross Hospital; H. J. de Sram, Middlesex Hospital; A. H. Fitzpatrick, St. Bartholomew's Hospital; W. M. Hocken, Liverpool and Edinburgh; H. G. Lewis, Edinburgh; E. P. Marett, St. Thomas's Hospital; W. P. R. Scott, St. Thomas's Hospital; J. Seare, Manchester.

Botany.—E. Yoxall, Birmingham.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

NOTIFICATION BY HOUSEHOLDERS.

A STRIKING instance of culpable negligence and its consequences was brought before the Borough Bench by the Wigan Corporation lately. A child was seized with small-pox, and died after several days' illness. No medical man seems to have been called in, and the case was concealed until death took place. The father took the infection, and ten or eleven other attacks were traced to the same source. The mother was summoned for failure to notify, and the only defence offered was that she was unwilling to have the child removed to hospital. A penalty of 40s. and costs was inflicted. In this matter the Corporation were well advised in taking proceedings. Where there is no medical attendant, and no possibility therefore of medical certification, notification by the householder should be strictly enforced.

WHAT IS AN "INHABITED HOUSE?"

At Bradford, on September 30th, the Pudsey Urban District Council obtained closing orders, under the Housing of the

Working Classes Act, with regard to a number of dwellings unfit for habitation. One of these had been empty for upwards of two years, but it was stated in evidence that the owner had some intention of repairing it for occupation. Another group of houses, however, which had been unoccupied for eighteen years were held to be exempt from the operation of the Act. The Bench expressed the opinion that where there was long disuse and no prospect of future occupation the premises were not to be regarded as inhabited houses within the meaning of the Act. It was thought that the section which empowers the court to issue a closing order, even if the house be unoccupied, bore reference merely to a temporary cessation of tenancy. It does not appear that any notice of appeal was given, but the decision is one which, if generally accepted, must hamper the action of public authorities in dealing with insanitary portions of their districts. The "closing order" is a necessary preliminary to the "demolition order," according to the Act, and the Bradford ruling would leave the worst houses standing, while affording facilities for the removal of the less bad.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 6,930 births and 3,919 deaths were registered during the week ending Saturday, October 11th. The annual rate of mortality in these towns, which had risen from 19.7 to 21.0 per 1,000 in the three preceding weeks, declined to 20.4 last week. The rates in the several towns ranged from 18.9 in Croydon, 14.2 in Huddersfield, and 14.4 in Brighton to 26.5 in Salford, 29.3 in Bolton, and 37.2 in Blackburn. In the thirty-two provincial towns the mean death-rate was 21.9 per 1,000, and exceeded by as much as 8.0 the rate recorded in London, which was only 15.9 per 1,000. The zymotic death-rate in the thirty-three towns averaged 4.2 per 1,000; in London the death-rate was 2.6 per 1,000, while it averaged 5.5 in the thirty-two provincial towns, and rose highest in Colchester, Salford, Bolton, and Southport. Measles caused a death-rate of 2.6 in Salford and 4.9 in Blackburn; scarlet fever of 1.1 in Gateshead and 1.2 in Wolverhampton; whooping-cough of 1.7 in Bolton and 3.6 in Wolverhampton; "fever" of 2.4 in Sunderland, and diarrhoea of 4.5 in Salford, Oldham, and Burnley, 8.2 in Bolton, and 10.3 in Blackburn. The 71 deaths from diphtheria in the thirty-three towns included 44 in London, 4 in West Ham, and 1 in Salford. One fatal case of small-pox was registered in London and 1 in Oldham, but not one in any other of the thirty-three towns. There were 163 cases of small-pox under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital on Saturday, October 11th, against 397, 371, and 564 at the end of the three preceding weeks; 17 new cases were admitted during the week, against 42, 23, and 21 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had increased from 2,597 to 2,897 at the end of the six preceding weeks, was 2,922 on Saturday last, October 11th; 289 new cases were admitted during the week, against 365, 344, and 339 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

In nine the week ending Saturday, October 11th, 591 births and 527 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 19.5 and 17.5 per 1,000 in the two preceding weeks, rose again to 19.3 last week, but was 1.1 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 16.6 in Edinburgh to 21.1 in Paisley. The zymotic death-rate in these towns averaged 1.5 per 1,000, the highest rates being recorded in Aberdeen, Leith, and Paisley. The 246 deaths registered in Glasgow included 57 from diarrhoea, 10 from whooping-cough, and 3 from scarlet fever.

EAST END WATER SUPPLY.

The report of the managers of the Poplar and Stepney Sick Asylum gives many details regarding the working of the institution, but the matter of greatest interest at the present moment is the amount given of the difficulties entailed upon the management in consequence of the imperfections and irregularities of the water supply. From a letter written to the secretary of the East London Water Company last January it appears that great inconvenience had been felt in consequence of the failure to get sufficient water to warm the buildings. The managers had at a very large expense fitted up a hot water service, and at the very moment when it was most required the service was frequently of little or no avail, because of the lack of water. This trouble was no exceptional affair, but usually arose as soon as the heat from the boiler made its appearance, so soon as the time arrived when the apparatus was required to perform the work for which it was intended, it became almost imperative on account of the lowness of the pressure. Nor was the trouble confined to winter only, for in summer also it was found that the pressure was often insufficient, so that the bath-tubs and wash-basins became very offensive through want of water to flush them. In addition to paying upwards of £10 per annum specially for the high water service, the managers had caused a pump to be attached to the engine for the purpose of aiding the pressure from the company's mains, but even this was of little or no avail for want of water to pump up. The result of this may be imagined when it is considered that the institution contains between 700 and 800 inmates.

LEICESTER AND HER MEDICAL OFFICERS OF HEALTH.

Mr. JOSEPH PRIESTLEY has commenced his duties as medical officer of health for Leicester, and the Town Council of Leicester at their last meeting elected as his successor Mr. H. E. H. Monk, M.R.C.S., L.S.A.

D.P.H., M.O.H., Southborough. The Town Council have presented Dr. Priestley with a testimonial, in which they express their appreciation of the way he has stamped on the small-pox epidemic whilst at their last meeting they also resolved to apply for a loan from the Local Government Board for the conversion of the remaining pairs and private into water-closets at an estimated cost of £1,000. Dr. Priestley advised some change in his last annual report, and to amend the matter was done by means of some carefully worded alterations, by which he showed the Council the greater incidence of typhoid fever on poor over-watered houses. The Town Council have also decided to appoint a female sanitary inspector on the suggestion of their late medical officer of health, Dr. Priestley.

FEE FOR ASSISTANCE GIVEN TO WORKHOUSE MEDICAL OFFICER. K. writes as follows: At the request of the workhouse medical officer I administered an anæsthetic and assisted at an urgent case requiring an operation. Am I entitled to a fee from the guardians and should I send in a claim to them? I should think one guinea would be reasonable.

"We question whether our correspondent has any legal claim on the guardians as he appears to have given his services at the request of the workhouse medical officer, but if he puts in a claim for the fee of one guinea the guardians doubtless have the power to pay it if they decide on doing so, and this will of course depend on the votes given for or against the resolution, if it should be proposed and seconded.

THE PROTECTIVE VALUE OF VACCINATION.

The following letter appeared recently in the *Star* and *A-S-S*.

THE VACCINATION FAD.

SIR,—“F. H.’s” is a very useful letter. It should be noted that the Local Government Board issue instructions under authority of an Order in Council which public vaccinators do not carry out. Light should be let in upon the practice of vaccination on every side. I have had within the last day or two a significant instance of the protective value of vaccination. Mr. L—, of Greenwich, and his wife were well vaccinated in infancy, as “small-pox was absent.” The husband yielded to persuasion and was re-vaccinated this year. In July last both he and his wife contracted small-pox, and were taken to the Long Reach Small-pox Hospital. *Verbum sapientibus*—Yours, etc., H. A. SCRIBBLE YOUNG.

16, Queen Anne's Gardens, Bedford Park, W.

We have made inquiries at the Metropolitan Asylums Board's hospital ships at Long Reach, and we are informed that the patients to whom Mr. Young refers were, it is believed, admitted to the ships at the end of May and beginning of June and not in July, as he says. The woman, aged 26, was admitted on May 25th, the fourth day of her rash. She had been vaccinated in infancy and had three small non-foreset scars; she had never been re-vaccinated. Her husband, aged 26, was admitted on June 6th, his rash having appeared on the fourteenth day after that of his wife. He had been vaccinated in infancy and had four non-foreset scars. He was re-vaccinated on May 28th, that is on the seventh day after the appearance of his wife's rash and on the eighth day before the appearance of his own rash. One would not expect that vaccination performed solely in the incubation period would have the effect of entirely preventing an attack of small-pox. Both these patients had very mild attacks of the disease.

The following facts may be interesting as affording some evidence of the protective value of vaccination. The infant son of the above parents, aged (months), was allowed to come to the ships with his mother, although he was not suffering from small-pox. He had been vaccinated when younger and was not re-vaccinated after admission. Although he lived for more than three weeks in a small-pox ward he did not contract the disease.

INDIA AND THE COLONIES.

THE CALCUTTA MEDICAL COLLEGE.—It is the practice in this institution to hold in each class at the end of each session a “test and honor” examination, which has been hitherto compulsory for both ordinary students, and optional for the rest. The option has been exercised by the majority of students to evade it. It has now been resolved to make this examination a real test of progress for all students, and to dismiss those who do not obtain a moderate percentage of marks. The rule, which has obtained the sanction of the Director of Public Instruction, has raised quite an agitation among the students and their friends, and in the native press. The circumstances of medical study in India are quite peculiar. A large proportion of students who enter on the course of study relinquish it on account of want of means, want of capacity, diligence, and application, and from other causes. Many of those who persevere do not succeed in obtaining a qualification, and set up in practice, regular or irregular, without one. Many of those who obtain a qualification do so by a painful process of repeated efforts and passing by examinations spread over six, seven, eight, or nine years. The new rule is intended to filter out the incompetents during the early stages of the curriculum and demonstrate to them practically that they have mistaken their calling and had better turn their attention to some other mode of obtaining a livelihood. It is now calculated to stimulate the capable but indolent to greater diligence and closer application. A rule of this kind obtains in some Scotch universities and English public schools. It is not enforced in medical colleges and schools in this country because it is not needed. But looking to the conditions of medical study in India which we have mentioned, the practice seems likely to be a salutary one, provided that it is carried out with discretion and kindness. The so-called test examinations in Indian medical colleges have hitherto been to a large extent a sham. The object is to make them real and helpful to students by showing them whether they understand and accomplish their work.

MEDICAL NEWS.

A PORTRAIT of the late Mr. Ernest Turner, F.R.I.B.A., Chairman of the Council of the Sanitary Institute, has been presented to the Institute by his widow, and has been placed in the library.

AN American paper states that a female medical practitioner has been elected City Physician and Coroner of Pender, Nebraska, after she had been but six months practising in the town.

WE stated last week that Dr. J. W. Jamieson had been appointed Sheriff Substitute of Banffshire. This is incorrect. The position to which Dr. Jamieson has been appointed is that of Honorary Sheriff Substitute to the Arran Division of Butehire.

A FEMALE DENTIST IN BOSNIA.—The Government of Bosnia has granted permission to Frau Emilie Edel to practise dentistry in any part of that country except in Sarajevo, the capital, which is already, it is officially declared, "sufficiently supplied with dentists." Frau Edel, who received her professional education in the Dental Institute of the Vienna University, proposes, it is stated, to settle in a town where the Mohammedan element predominates in the population.

THE MANUFACTURE OF ANTITOXINS IN NEW YORK.—The New York Pasteur Institute has purchased thirty-five acres of land near Tuxedo Park, on which an experiment station is to be established. It will be stocked with cows, horses, sheep, and goats, which will be used for the production of diphtheria and cancer antitoxins. The situation is healthy, and in the grounds there will be a house in which some of the patients of the Institute will be treated. A new station, to be known as the Pasteur Station, will be established on the Erie Railroad close at hand.

ENDOWMENT OF HOSPITAL BEDS.—Mrs. Saxton, of The Elms, Shrewsbury, has made a benefaction from the Gwyn Trust Fund to the Salop Infirmary, the interest of which is to be devoted to the maintenance in perpetuity of two beds in the children's ward. Over each bed a brass plate will be fixed, with the following inscription: "This bed was endowed by Caroline Saxton, widow of the Rev. Charles Waring Saxton, D.D., in memory of her parents, for the special use of children—1895."

MEDICO-PSYCHOLOGICAL ASSOCIATION.—A meeting of the South-Western Division of the Medico-Psychological Association will be held at Wonford House, Exeter, on Tuesday, October 15th. Dr. Deas will open a discussion on the Uses and Limitation of Mechanical Restraint as a Means of Treatment. Dr. Macdonald will read a paper on the Nursing Staff: Thoughts and Reflections, with Remarks on a New Departure; and Dr. Morton one entitled, Notes on Three Cases of Spontaneous Gangrene.

THE President of the Society for the Study of Inebriety, Dr. Norman Kerr, in opening a discussion on the proposed probationary curative detention of inebriates and others deemed to be insane, at the last meeting of the Society, said that at present many inebriates and other persons were certified as lunatics and sent to asylums for the insane, who might have been cured under a better legislative state of things. He ventured to predict that in twenty years or so more there would be: (1) Probationary curative mental hospitals; (2) Asylums not in one block, but in a number of smaller buildings as in some American asylums; (3) Mental convalescent homes, where the discharged from the asylum could be received for a few weeks, to render the re-entrance of the convalescent into the world less trying, a work to some extent attempted at present by the excellent After-Care Association. Drs. Longhurst, Parker Young, Smith, and Weber approved of the proposal.

THE third annual meeting of the Society of Anaesthetists will be held at Limmer's Hotel, Conduit Street, W., on Thursday, October 17th, 1896, at 7 p.m., to receive the reports of the Council and Treasurer, and to elect the officers and Council for the ensuing year. The following list will be submitted to the meeting, namely:—President: Mr. G. Hewlett Bailey. Treasurer: Dr. Dudley W. Eustace. *Elect Members*

of Council: Dr. J. Frederick W. Silk, Dr. A. E. Bridger, Mr. E. A. Starling (Tunbridge Wells). Secretaries: Mr. Walter Tyrrell, Mr. O. C. Braine, F.R.C.S. Auditors: Mr. Richard W. Lloyd, Dr. T. Sydney Short (Birmingham).

WEST KENT MEDICAL SURGICAL SOCIETY.—The annual general meeting of the Society was held on Friday, October 4th, at Greenwich, when the following officers were appointed for the ensuing year:—President: Ernest Clarke, M.D., B.S.Lond., F.R.C.S. Vice-Presidents: Peter Cooper, M.R.C.S., L.R.C.P.; Frank Tayler, B.A., M.B.Lond. Council: A. Stewart Brown, F.R.C.S.Edin.; Morgan Dockrell, M.A., B.Ch., M.D.Dub.; George Herschell, M.D.Lond.; Arbutnot Lane, M.S.Lond., F.R.C.S.; Clarke Morris, M.R.C.S.; O. J. Parke, M.R.C.S.; Septimus Sunderland, M.D.Brux. Treasurer: Prior Purvis, M.D.Lond. Secretary: E. H. Ezard, M.D., C.M., D.Sc.Edin. Librarian: J. P. Henry, B.A., M.D., B.Ch.Dub. The Purvis Oration was delivered by Professor Curnow, who chose for his subject "Medical Examination and Education."

ENTRANCE SCHOLARSHIPS.—At St. Thomas's Hospital Medical School the first entrance scholarship in Natural Science, of the value of £150, has been awarded to Mr. Frank B. Skerrett; the second, of the value of £60, being divided between Messrs. Walter B. Fry, George W. Hare, and Alfred B. Lindsey, bracketed equal. The entrance scholarship, value £50, for students from the universities, has been awarded to Mr. Percy W. G. Sargent, B.A., of St. John's College, Cambridge.—At St. Mary's Hospital Medical School the two university scholarships, of the value of £52 10s. each, have been awarded to Mr. R. Wade, B.A., of Exeter College, Oxford, and Mr. G. S. Keeling, B.A., of Caius College, Cambridge. The first Natural Science scholarship, value £105, has been awarded to Mr. W. H. Wilcox, and the three value £52 10s. each to Messrs. H. Lovell-Keays, E. W. Holyoak, and A. F. Hayden.—St. Bartholomew's Hospital is specially rich in endowed scholarships, and five of these are awarded to students just entering upon their medical studies. The competition which was held on September 25th and following days has resulted in the following awards:—(1) Scholarship of £75 in biology and physiology for students under 25 years of age to Mr. O. S. Myers, B.A., Caius College, Cambridge; (2) the scholarship of £75 in chemistry and physics for students under 25 years of age to Mr. J. S. Williamson, Preliminary Scientific University of London; (3) the scholarship of £150 in biology, chemistry, and physics for students under 20 years of age to Messrs. R. C. Bowden and R. H. Paramore; (4) the preliminary scientific exhibition of £50 in biology, chemistry, and physics for students under 20 years of age to Mr. J. C. M. Bailey, Preliminary Scientific University of London; (5) the Jeaffreson exhibition of £20 in classics and mathematics to Mr. H. A. Kellond-Knight, Matriculation University of London.—The entrance scholarships at the London Hospital Medical School have been awarded as follows: Price Scholarship in Science, £120, Mr. H. Balean; Science Scholarships, £50 and £45, Mr. O. Nichholz and Mr. A. B. Soltan; Price Scholarship in Anatomy and Physiology for University Students, £50, Mr. R. C. Wall and Mr. J. H. Evans.

MEDICAL VACANCIES.

The following vacancies are announced:

ARMAGH UNION.—Medical Officer for the Richhill Dispensary District. Salary, £120 per annum as Medical Officer and £20 per annum as Sanitary Officer, together with vaccination and registration fees. Applications to F. J. Best, Honorary Secretary, Richhill, before October 14th.

BELGRAVE HOSPITAL FOR CHILDREN, 77 and 79, Gloucester Street, S.W.—Surgeon to Out-patients; must be F.R.C.S.Eng. Applications to the Honorary Sec. return by November 2nd.

BOROUGH OF SCARBOROUGH.—Medical Officer of Health. Salary for the first year, £325, for the second, £350, and 1 for the third and following year, £375. Will be required to act as Public Analyst at a further salary of £25 per annum. Not less than 25 or more than 40 years of age. Applications to John T. Graham, Town Clerk, Town Hall, Scarborough, by October 21st.

CARLTON JOINT SANITARY DISTRICT.—Medical Officer of Health, must be between 25 and 40 years of age, doubly qualified. Must devote his whole time to the duties, and have a knowledge of the Welsh language. Appointment for five years. Salary, £200 per annum, inclusive of all expenses, except those incurred for such books, stationery, and apparatus required in the performance of the duties. Applications, endorsed "Application for Office of M. O."

Health," to J. H. Thomas, Clerk, to the Joint Committee, 14, Market Street, Carnarvon, by October 16th.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY, Chesterfield.—Junior House-Surgeon and Dispenser. Salary, £50 per annum, with board, apartments, and laundress. Applications to the Secretary by October 15th.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, 10, Abchurch Lane, Shadwell, E.—Assistant Physician to see out-patients. Must be Fellow or Member of the Royal College of Physicians of London. Applications to Thomas Hayes, Secretary, by October 20th.

EAST SUSSEX COUNTY COUNCIL.—Consulting Medical Officer. Appointment for one year. Honorarium, 100 guineas and travelling expenses. Applications to F. Ferrisfield, Clerk to the County Council, County Hall, Lewes, by October 14th.

ESSEX AND COLCHESTER HOSPITAL.—House-Surgeon, doubly qualified. Salary, £80 per annum, with board and lodging in the hospital. Applications to the Committee by October 15th.

GENERAL HOSPITAL, Birmingham.—Assistant House-Surgeon. Appointment for six months. No salary, but residence, board, and washing provided. Applications to Howard J. Collins, House-Governor, by October 20th.

GLASGOW MATERNITY HOSPITAL.—Obstetric Physician and Assistant Obstetric Physician. Applications to Arthur Forbes, Secretary, 145, Buchanan Street, Glasgow, by November 8th.

GUEST HOSPITAL, Dudley.—Resident House Surgeon. Appointment for six months. Board, lodging, and washing in hospital. No salary. Applications to the Secretary.

LONDON HOSPITAL, Whitechapel, E.—Medical Electrician, must be qualified and registered under the Medical Act. Applications to G. Q. Roberts, House-Governor, by October 15th.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Resident Medical Officer for the Institution at Bowdon, Cheshire. Salary, £50 per annum, with board, apartments, and washing. Applications to C. W. Hunt, Secretary, by October 14th.

METROPOLITAN ASYLUMS BOARD.—Assistant Medical Officer at the Western Hospital for Fever Patients, Seagrove Road, Fulham, S.W. Doubly qualified, unmarried, and not more than 35 years of age. Applications, on forms to be obtained at the offices of the Board, Norfolk House, Norfolk Street, Strand, to be sent in by October 17th.

NORFOLK COUNTY ASYLUM, Thorpe, Norwich.—Junior Assistant Medical Officer. Salary, £110 per annum, with £10 annual increase to £120, with board (no liquor), lodging, and washing. Unmarried, and not more than 35 years of age. Applications to Dr. Thomson, Medical Superintendent.

NOTTINGHAM GENERAL DISPENSARY.—Junior Assistant Resident Surgeon. Appointment for six months. Salary at the rate of £120 per annum, with rooms, fire, and attendance. Applications to the Resident Surgeon, Broad Street, Nottingham, by October 22nd.

OLDHAM INFIRMARY.—Junior House-Surgeon; doubly qualified. Salary, £50 per annum, with board and residence. Applications to E. L. Blake, Secretary, by October 22nd.

PALISH OF DUNESS, Rutherslandshire.—Medical Officer. Guaranteed salary, £50 per annum, with practice, free house, and garden. Applications to Robert Sutherland, Inspector of Poor, Duness, by October 15th.

ROYAL BERKSHIRE HOSPITAL.—Consulting Dentist; must be registered Licentiate in Dental Surgery. Applications to the Secretary ten days before the election on November 3rd.

ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.—Resident Medical Officer (House-Physician); doubly qualified. Appointment for six months but eligible for re-election. Board, residence, and washing provided. No salary. Applications to the Secretary by October 15th.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.—Resident Medical Officer. Appointment for six months, when re-election is required. Salary at the rate of £100 per annum, with furnished apartments and board. Applications to the Secretary by October 15th.

RURAL DISTRICTS OF BUNTINGFORD, HADHAM, HERTFORD, STANFORD, AND WARE, AND THE URBAN DISTRICTS OF BISHOPS STORTFORD, HERTFORD, HUNDESDON, AND WARE.—Medical Officer of Health; must devote his whole time to the office. Salary, £200 per annum, including travelling and other expenses. Applications to George H. Gossy, Clerk to the Joint Committee, Council Office, Baldock Street, Ware, Herts, by October 21st.

ST. MARLEBONE GENERAL DISPENSARY, 77, Welbeck Street, Cavendish Square.—Assistant Resident Medical Officer; doubly qualified. Appointment for six months. Salary at the rate of £50 per annum, with furnished apartments, attendance, coal, and light. Applications to the Directors by October 15th.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—Assistant House-Surgeon. Appointment for six months, but renewable for a further period of six months. Board and residence and an honorarium of £20. Applications to J. Walter Wilson, Honorary Secretary, by October 15th.

STOURBRIDGE DISPENSARY.—House-Surgeon and Secretary. Salary, £100 per annum, increasing £5 a year to £125, with furnished rooms, coal, gas, and extra allowance of £25 for travelling expenses. Applications to the Honorary Secretary, T. F. Nield, The Firs, Norton, Stourbridge by October 24th.

SUSSEX COUNTY HOSPITAL, Brighton.—Fourth Resident Medical Officer, doubly qualified, unmarried, and under 35 years of age. Salary not exceeding £50 per annum, with board, washing, and residence in the hospital. Applications to the Secretary by October 22nd.

MEDICAL APPOINTMENTS.

ASPINALL, J. M.R.C.S. Eng. L.S.A., appointed Medical Officer of Health for the Smallborough Urban Sanitary District, vice J. B. Walker, M.D. and M.R.C.S. Eng.

ATKINSON, C. H. A. M.R.C.S. Eng. L.S.A., reappointed Medical Officer for the Fourth District of the East Ashford Union.

BEAUMONT, Albert Wm., B.A. Camb. L.R.C.S. Edin., reappointed Medical Officer of Health to the East Ham District Council.

BROOKMAN, Mr. Arthur, appointed Medical Officer of Health to the Newcastle Rural District Council.

BOWLES, Dr., appointed Medical Officer for the Sixth District of the East Ashford Union.

DON, Ahy., M.H. C.M. Aberd., appointed Assistant Surgeon, Dundee Royal Infirmary.

ELIUS, W. C. L.R.C.P., L.R.C.S. Edin., appointed Medical Officer for the Tollerston District of the Easingwold Union.

GARLAND, E. C. L.R.C.P. Edin. M.R.C.S. Eng., appointed Medical Officer of Health for the Borough of Yeovil.

GREIG, David M., M.B., C.M. Edin., F.R.C.S. Edin., appointed Surgeon to the Dundee Royal Infirmary, vice C. Templeman, M.D., D.Sc. Edin., resigned.

GRIFFITHS, J. H. R., M.B., C.M. Edin., appointed House-Surgeon to the Carmarthenshire Infirmary, vice J. J. Evans, M.B., C.M. Edin., resigned.

GROOM, H. B.A. Camb. M.D., M.R.C.S. Eng., reappointed Medical Officer of Health to the Walsoken Urban District Council.

HALL, George, M.B., C.M. Edin., appointed Assistant Surgeon to the Dundee Royal Infirmary.

HOWARD JONES, J., D.Sc. Pub. Health, M.B., C.M. Edin., appointed Medical Officer of Health, Medical Officer to the Port Sanitary Authority, etc., of the Newport (Mon.) Town Council.

KNIGHT, Henry, M.R.C.S., L.R.C.P., appointed House-Surgeon at the West London Hospital, Hammersmith, W.

MCCORMACK, Charles Vincent, L.R.C.P. Lond., M.R.C.S. Eng., appointed Medical Superintendent of the Corporation Hospital, Botic, Lanes-shire.

MERSON, Adam G., L.R.C.P., L.R.C.S. Edin., appointed Parochial Medical Officer for Aberdour and District.

MILNER, Cyril W., M.R.C.S., L.R.C.P., appointed Assistant Resident Medical Officer to the Nottingham General Dispensary.

MORGAN, H. de R., M.A. Oxon, L.R.C.P. Lond., M.R.C.S. Eng., reappointed Medical Officer of Health for the Cockington Urban District Council.

MOXON, Wm., L.R.C.P. Edin., M.R.C.S., reappointed Medical Officer for the Matlock District of the Bakewell Union.

SANDFORD, H. V., L.R.C.P. Lond., L.F.P.S. Glasg., reappointed Medical Officer of Health to the Bromyard District Council.

STANLEY, Dr., appointed Medical Officer for the Fifth District of the East Ashford Union.

STANLEY, Mr. H., appointed Medical Officer for the Sellindge District of the Elham Union, vice L. M. Snow, L.R.C.P. Lond., M.R.C.S., resigned.

STEPHENS, William J., M.R.C.S., L.R.C.P., appointed Senior Resident Medical Officer to the Nottingham General Dispensary, vice H. Balcher, resigned.

STYKES, John F. J., M.D., D.Sc., L.R.C.P., M.R.C.S., Medical Officer of Health for St. Pancras, appointed Lecturer on Public Health at Guy's Hospital Medical School.

TEMPLEMAN, Charles, M.D., D.Sc. Edin., appointed Medical Officer of Health for Dundee, vice Dr. Anderson, resigned.

TRE, J. Scott, M.D., D.P.H., appointed Medical Officer of Health for the West Kent Combined Sanitary District, vice H. Butterfield, M.R.C.S., deceased.

THOMAS, P. M., M.D. Cleveland, L.S.A., appointed Medical Officer for the Cornhill District of the Carmarthen Union, vice J. N. Edwards, M.R.C.S. Eng., L.S.A., resigned.

VINCENT, Henry Bird, M.R.C.S. Eng. L.S.A., reappointed Medical Officer for the East Dereham Union District.

WILKIN, R. H., M.R.C.S., L.R.C.P., appointed Medical Officer for the Fifth District of the Risbridge Union, vice R. W. Bateman, M.R.C.S., L.S.A., resigned.

WILLIAMSON, George A., M.A., M.B., C.M. Aberd., appointed District Medical Officer in the Island of Cyprus.

WILSON, J. H., M.B., C.M. Edin., appointed Medical Officer of Health for the Stanish with Lagrange Urban Sanitary District and Medical Officer for the Stanish District of the Wigan Union, vice J. A. Marsden, M.R.C.S., L.S.A.

WORSLEY, H. M.B., C.M. Edin., appointed Medical Officer of Health for the Church Urban Sanitary District, vice W. Lloyd.

ERRATUM.—In the notice of the appointment of Dr. Robertson last week it should have been "appointed Medical Officer for the Farnham Rural District of the Farnham Urban Union," instead of "Medical Officer of Health for Peterborough." Dr. William J. Jones holds the appointment of Medical Officer of Health for Peterborough.

DIARY FOR NEXT WEEK,

TUESDAY.

LONDON POST GRADUATE COURSE, Royal London Ophthalmic Hospital, Moorfields, 1 P.M.—Mr. W. Long: Lachrymal Affections. **LONDON TUBERCULAR HOSPITAL, Great Portland Street, 5 P.M.**—Dr. Edward Law: Examination of the Throat and Nose.

MEDICAL SOCIETY OF LONDON, 8 P.M.—General meeting. 8.30 P.M.—Ordinary meeting. Opening Address by the President (Mr. J. Trichon Brown, F.R.S.) On the Generalisation of Specialism. Mr. C. B. Lockwood: The Operation for the Radical Cure of Hydrocele by Excision of the Sac. Illustrated with a series of cases.

TUESDAY.

LONDON POST GRADUATE COURSE, Bethlem Royal Hospital, 2 P.M.—Dr. Craig: Melancholia.

MEDICO-PSYCHOLOGICAL ASSOCIATION: SOUTH-WESTERN DIVISION, Wotton House, Exeter, 2.30 P.M.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 2 P.M.—Lecture at 4.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 P.M.—Drs. Ord and Howright: Spontaneous Disruption of Uterus. Mr. D'Arcy Power: Primary Sarcoma of Vagina of Child. Dr. Wm. Collier: Multiple Polyp of Stomach and Intestines. Mr. Jackson Clarke: Tertiary Syphilitic Lesions in Lymphatic Glands. Dr. Herbert Snow: The Non-existence of Round-celled Sarcoma as a Distinct Class of New Growth. Card Specimens by Dr. Kanthack and Mr. Targett.

WEDNESDAY.

LONDON POST GRADUATE COURSE, Royal London Ophthalmic Hospital, Moorfields, 8 P.M.—Mr. A. Stanford Morton: Retinal Affections.

WEST LONDON HOSPITAL, Hammersmith, W., 5 P.M.—Dr. Abraham: Dermatological Cases (Post-graduate course).

NORTH-WEST LONDON CLINICAL SOCIETY, North-West London Hospital, Kentish Town Road, 8.30 P.M.—Clinical Meeting.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover Square, W., 8 P.M.

THURSDAY.

LONDON POST GRADUATE COURSE, Hospital for the Paralysed and Epileptic, Queen Square, 2 P.M.—Dr. Ormerod: Ataxia. Hospital for Sick Children, Great Ormond Street, 3.30 P.M. Mr. C. A. Balance: Selected Surgical Cases. Central London Sick Asylum, Cleveland Street, 5.30 P.M. Dr. Patrick Manson: Sprue.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos Street, Cavendish Square, W.—Card Specimens at 8 P.M. by Mr. Ernest Clarke, Dr. Mott, Mr. Treacher Collins, and Mr. Lawford. 8.30 P.M.—Introductory Address by the President. Papers.—Mr. Treacher Collins: Four Cases of Bilateral Glioma of the Retina, cured by Enucleation of Both Eyes. Mr. Kenneth Scott: Keratitis occurring in Leprosy. Mr. Devereux Marshall: Detachment of the Cornea.

HARVEIAN SOCIETY, 8.30 P.M.—Dr. E. Symes Thompson: On the Climate of Egypt.

FRIDAY.

LONDON POST GRADUATE COURSE, Bacteriological Laboratory, King's College, 8 to 6 P.M.—Professor Crookshank: Lecture: the Examination of Air, Soil, and Water. Practical Work: Plate Cultivations.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 4 P.M.—The Harveian Oration by Dr. W. S. Church.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION, 8 P.M.—Cases will be shown by Dr. Edward Law, Dr. Geo. Stoker, Dr. Wm. Hill, Dr. Dundas Grant, and Mr. Bark. Paper by Mr. R. Lake on Keratosis Obturans. Discussion on the Treatment of Ménière's Complex of Symptoms. Inaugural Address by the President.

SATURDAY.

LONDON POST GRADUATE COURSE, Bethlem Royal Hospital, 11 A.M.—Dr. Percy Smith: Hypochondriasis.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 2s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

DOUGLAS.—On September 26th, at Sanchez, Santo Domingo, the wife of Robert Douglas, M.B., C.M., of a son.

GREENLEES.—On September 12th, at the Residence, Grahamstown, South Africa, the wife of Dr. T. Duncan Greenlees, of a daughter.

ROBSON.—On October 6th, at Castle House, Banbury, the wife of Frederick Robson, M.B., B.S., of a daughter.

MARRIAGE.

ATLER-STUART.—On October 9th, at St. Saviour's, Clapham, by the Rev. H. Hughes, assisted by the Rev. D. H. Davys, John Atlee, M.D., Cantab. of 58, Brook Street, W., son of John Atlee, of Rose Hill, Dorking, to Edith Mary, elder daughter of John Stuart, of "The Hollies," Clapham Common, and of Stonehurst, Ardingly, Sussex.

DEATH.

THOMSON.—At Johannesburg, South Africa, William Sinclair Thomson, M.D., formerly of Palace Court, London, aged 60. (By cablegram.)

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

ED. H. asks whether there is any place near Westminster where a patient could have certain exercises for a stiff hip.

HIGH PEAK asks what is the best prescription for the administration of mercury by inunction, (1) having in view its easy absorption, and (2) the disadvantages of the colour of the unguentum hydrargyri B.P.

PREVENTION OF MIGRAINE.

SUBSCRIBER writes: A lady, aged 39, has suffered for ten years from frequent attacks of migraine; the longest remission she has had has been fourteen days before and after an attack. On an average she has one a week. She has been under my care for three months, during which time she has been strictly dieted, taking only one meal a day, with plenty of bread-and-butter, eggs, milk, puddings, fruit, etc.; no stimulants.

LIGHT-COLOURED FACES.

ENQUIRENS writes: A patient of mine has for some months noticed, and occasionally shown me, that his daily fecal excretion is in colour light as a canary's plumage, although his health is good, and he in no way appears to suffer from bile suppression. His diet is an egg, about six ounces of meat or fish, a quart (or slightly more) of milk, much green vegetables, fruit, weak tea and coffee, all sorts of puddings and bread stuffs. The mass is rather dry, and non-adherent, and in no way "putty" like, as in the case sometimes of infants. I should like to know if it be of any importance as my patient supposes. Blue pill and mist. sennæ co. cause no change.

BOOKS AND DIAGRAMS FOR LECTURES ON HYGIENE.

X. asks the following question: I have been asked by the County Council to give popular lectures on hygiene; can you recommend a suitable book, and where could I get any diagrams?

* The necessary diagrams could doubtless be obtained of Baillière, Tindall, and Cox, 20 and 21, King William Street, Strand. Useful books would be the *Manual for the Medical Staff Corps*, published by Harrison, St. Martin's Lane; and *Martin's Ambulance Lectures*, published by Messrs. Churchill.

ANSWERS.

M.D.—The matter is not one in which we feel concerned.

A. V. L.—The proportion of ammonia in the prescription mentioned would not injure any ordinary scalp, and whether an acid stimulant would do better would depend on the case. The dyeing of hair is the work of a hairdresser.

DR. CARRY COOMBS (Castle Cary) writes in reply to "Horseflesh" that he will find Courtenay's *Veterinary Medicine*, published by Baillière, Tindall, and Cox (10s. 6d.), an excellent work, and that Messrs. Routledge publish a shilling book which will give the main points for a buyer.

MEDICUS.—The report of the Committee appointed to investigate the Nature of the Phenomena of Hypnotism was published in the BRITISH MEDICAL JOURNAL of July 26th, 1895. It was presented at the annual general meeting at Newcastle on August 1st. The report was then received, and the Committee thanked for their services.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

J. M. writes: If M.B., B.A., who wrote in the BRITISH MEDICAL JOURNAL of September 14th will write to Mr. J. B. Blackett, Secretary of the above Society, 11, Chandos Street, W., he will get all the information he requires.

LANTANA.

Messrs. THOMAS CHRISTY AND CO. (London) write with reference to the note on lantana, published in the *EPITOME* of October 6th, that they have for some years kept a stock of this herb, and are ready to supply samples.

DIPLOMA IN STATE MEDICINE.

M. D.—We have every reason to believe that the M. D. in State Medicine of the University of London is in all respects such a degree as will satisfy the requirements of the Local Government Act of 1882. We doubt if a higher degree in public health work can be obtained.

MECHANICAL ROAD CARRIAGES.

Dr. WALTER LATTY (Southam) writes in reply to "S. E.": A short time since, I obtained an illustrated catalogue (ed.) from the Daimler Petrol-motor Syndicate, of 65, Billiter Buildings, E.C., and find that the prices range from £150 for a two-seated carriage to £222 for a goods van. In these light petrol-motors oil is used, but some English firms manufacture motors for heavy oil, and claim advantages for the motor.

"PREMIER MEDICAL AID SOCIETY."

J. G. O.—From the statement forwarded by our correspondent, it would seem that this Society is very different from all the medical aid societies with which we are acquainted. If these facts be verified he must take his own course. We cannot take the responsibility of advising him, seeing how often in such societies the facts of working do not accord with the promises made.

THE METRIC SYSTEM AND THE "BRITISH PHARMACOPOEIA."

Dr. F. J. JOHNS (Dursley).—As was stated in the *BRITISH MEDICAL JOURNAL* of August 17th, Dr. Donald MacAlister announced at the annual meeting of the British Medical Association, that the metric system would be introduced into the revised edition of the *British Pharmacopoeia*. To facilitate transition, the official proportions in the *Pharmacopoeia* articles will be given in the old as well as in the metric system, but in all gravimetric and analytical operations, the metric system alone will be made authoritative.

WATER FILTERS.

M. D.—The statement marked by "M. D." we should judge to be correct. The report in question was only intended to separate those filters which were grossly useless or dangerous from those which were not. The results of Dr. Johnston were summarised in the *BRITISH MEDICAL JOURNAL* of December 29th, 1881, p. 1495; and the much longer experience of the Prussian War Office Laboratory recently published shows that the Berkefeld filter was not more permanently reliable than the other imitations of Pasteur's apparatus and cannot safely be used except subject to daily bacteriological control.

CURE BY DISSEASE.

FOZEBEL writes, in answer to Dr. Campbell's second query in the *BRITISH MEDICAL JOURNAL* of September 28th: A patient who had suffered from chronic gonorrhoea or gleet for about four years contracted syphilis. He had discontinued all treatment for his "gleet" for months. About ten days after the appearance of the hard chancre the discharge entirely disappeared, and did not recur. The man was being treated for his syphilis by mercury and iron internally and black wash locally. Was the "cure" of the gleet due (1) to the presence of the chancre (it was on the trismus, counter-irritation, or (2) to the mercurial treatment, or (3) to the mental effect, the presence of a new disease distracting his attention from the less. This last seems far-fetched.

PAY AND PENSION IN THE MEDICAL SERVICES.

A Surgeon-Lieutenant Army Medical staff is never "appointed" to a post in India. There is no such regimental system in the A.M.S. The Surgeon-Lieutenant's pay A.M.S. in India is Rs. 317 a month, commencing up to five years, when he gets a slight increase of Rs. 25 per mensem, and a substantial increase after six years' service. An Indian Medical Service officer is not eligible for regimental duty till he has acquired a knowledge of the native language. Special regulations are in force as to the pay and retired pay of Indian Medical Service officers, and these are obtainable by application at the India office in person or by letter. (b) The retiring pensions are totally different in the Army Medical Staff and Indian Medical Service. The latter service is better off, for an officer of twenty-five years' service gets £200 a year retirement, while an Army Medical staff officer can only obtain this sum if selected for promotion to Brigade-Surgeon's rank. If a Surgeon-Lieutenant-Colonel A.M.S. is not selected for promotion, he cannot get a higher pension than £150 a day, and that only after thirty years' service; after twenty-five years' service he can obtain £125 a day. (c) Generally speaking, the Indian Medical Service as to pay and retirement has the advantage everywhere. The rates of pay and retirement A.M.S. are laid down in the Royal Warrant, Pay and Pensions, etc., 1882, which only costs 1s.

MANUAL OF ORAL INSTRUCTION FOR THE DEAF AND DUMB.

Mr. JOHN HARRIS (Stroudsburg, N.W.) writes: In reply to "Surdus" I would say that a very strong argument in favour of the superiority of the "oral" method over the manual in the instruction of deaf children is its almost universal adoption within the last twenty years. If we look on the Continent we find France and Italy entirely converted to the oral method, Germany tolerating no other. In England all the private schools are oral, which may also be said of the greater number of the public institutions. In the United States of America, too, where so much is spent by the Government in the education of the deaf, oral instruction is very generally on the increase. I believe too the oral method has been adopted by most of the school boards in England and most, and which have conducted classes for their deaf children, if not all of them. After nearly forty years' experience as a teacher of the deaf, during which I have taught on both systems, I find I can give as good a general education by the oral as by the manual method, with the great additional advantage to the pupil of being able to speak and understand to a great extent the speech of others.

NOTES, LETTERS, Etc.

"GUINEA GORGES."

Mr. J. LAWRENCE HAMILTON, M.R.C.S. (Brighton) writes to protest against what he calls the "guinea gorges" held in connection with many medical schools at the beginning of a session. He thinks the charge too high and the fare unnecessarily luxurious. The charge for a meal without wine, sufficient for the occasion, ought not, in his opinion, to exceed 3s.

THE AIRD JOLLY FUND.

Mr. GARRY HIMPSON, Treasurer (East Acton, London, W.) begs to acknowledge the following additional subscriptions:

	£ s. d.
Thomas Barlow, M.D., London	1 1 0
Sir Hugh Beaver, Bart., M.D., London	1 1 0
Dr. G. Vere Benson, M.A. Camb., Deputy Coroner, Middlesex	0 10 4
F. Woodhouse Braine, F.R.C.S., London	1 1 0
Dr. F. C. Dodsworth, Manchester	1 1 0
William Dyson, M.D., Sheffield	1 1 0

THE PROVISION FOR INFECTIOUS DISEASES IN THE METROPOLIS.

Mr. CLARK WAKEFIELD, F.R.C.S. Edin. (Notting Hill) writes confirming from his own experience the remarks which we recently made regarding the insufficiency of the accommodation now existing for the reception of cases of infectious disease in London. He states that a child was brought to him on a Monday evening, suffering from diphtheria; that the Asylums Board authorities are requested to remove it at once; that the next day the parents, hourly expecting the ambulance, did not send for him till evening, when they had given up all hope of the patient being removed; that on arrival he found the child apparently moribund from laryngeal obstruction; that he immediately performed tracheotomy; and that the child was not removed to hospital till the Wednesday. He justly adds that the delay in treatment might have proved a serious matter.

THE TREATMENT OF CARBOLIC ACID POISONING.

Dr. S. HERBERT PERRY (Spalding) writes: Dr. A. W. Shepherd considers the use of oil in cases of poisoning by carbolic acid objectionable because carbolic acid is very soluble in oil. He does not seem to distinguish sufficiently between the caustic and toxic actions of carbolic. In a case of poisoning by liquefied carbolic acid the most urgent indication is to prevent the caustic action from doing more damage than it has already done. Now, there are two ways of doing this: one by removing the poison; another by neutralising it.

Oil acts completely as an antidote to the caustic action of carbolic acid, and is far more readily miscible with the liquefied form than is water or any saline solution. Rapidity of action is, of course, absolutely essential; and therefore it is better to use oil at first, in spite of its not destroying the physiological action of the acid.

To my mind the oil should be given before a stomach tube is used; because of the high specific gravity of the liquefied carbolic acid, which would naturally cause delay in its removal by water, because of the slowness with which it is dissolved in water or saline solutions, and because of its great solubility in oil. If sufficient oil were at hand it would be preferable to wash the stomach out completely with oil. It would, of course, be absolutely unjustifiable to give oil and leave the poison in the stomach (a possibility which Dr. Shepherd seems to suggest).

One objection that I have heard raised to the use of oil is that it would simply lie on the wet surface of the stomach, and not coming in contact with it, would have no demulcent action. If, however, a little oil be poured on the surface of an aqueous solution of carbolic acid it will very soon remove the greater part of the carbolic from the water, and this it will do with great rapidity if they be well agitated, as would occur in the stomach.

One dangerous treatment is recommended in some books, and that is the immediate administration of emetics, which simply repeats the cauterisation of the oesophagus, etc., by the ascent of the carbolic, which has already taken place once too often in its descent. After the carbolic acid has been dissolved by the oil and removed by the tube "for the treatment of the general symptoms following carbolic acid poisoning, and to aid the elimination in the urine, the administration of sulphates, for example, sodium sulphate in large doses, is advisable" (vide Dr. Lauder Brunson's *Magnesium* work on *Pharmacology, Therapeutics, and Modern Medicine*, third edition, p. 312).

A NEW LEPROSY COLONY.

Colonel GENERAL MICHELL, of St. Petersburg, in his latest report to the Foreign Office, abstracted in the *Globe*, states that the number of lepers in the province of St. Petersburg has for some time past been found to be on the increase, while no measure of improvement existed for their treatment and isolation. This lamentable state of things has at last been remedied by the establishment of a leprosy colony near Yamburg, a district town of the province of St. Petersburg. Accommodation is there provided for 25 lepers of both sexes, and a surgeon and sister of mercy are on the staff of attendants at the institution, which was endowed with the acres of land by the late Emperor. His Majesty also contributing £1,000 towards defraying the cost of establishing the colony. A further sum of £1,000 was obtained from private charity. The lepers not in an advanced stage of the disease will be employed in cultivating the land allotted to them, so that the institution will to a certain extent be self-supporting. The Committee of Management appeal to the public for donations in order to place the asylum on a secure foundation. Its Lady President is the Countess Thun, wife of the Provincial Governor, and it is owing to her philanthropic efforts, in which she was aided ably by Dr. Karmalitz, that the foundation of this much-needed asylum is due. The opinion prevails that leprosy has spread to the province of St. Petersburg from neighbouring Estonia, where the disease has long existed and where two special leprosy hospitals exist for its treatment.

LEGISLATION FOR INEBRIATES IN AUSTRIA.

THE Austrian Government has prepared a bill for legislative procedure with habitual drunkards, which embodies the principal suggestions of the Association Inebriates Legislation Committee and the Society for the Study of Inebriety. The authorities of the State, the provinces, the districts, and the communes are to be empowered to establish and maintain retreats. Voluntary and involuntary patients are to be provided for; the former, except as to admission into a retreat, are to be treated in the same way as patients who may be compulsorily sent in, the maximum period of detention being two years, as recommended by the recent English Departmental Committee. Involuntary patients may be committed to the district retreat, either by a magistrate's order, or on the petition of the parents or children, or of the husband or wife or trustee, or of the head of a lunatic asylum of which the drunkard may be an inmate, by the action of the public prosecutor, or by the mayor or burgomaster of the town or village where the inebriate resides. Compulsory commitment must be ordered only after an ordinary judicial action before a Court of First Instance, where the evidence is to be taken, inclusive of that of the alleged drunkard and of medical witnesses, especially experts. Among the circumstances proposed to constitute an habitual drunkard and involving curative sequestration by judicial process is a record of three convictions within twelve months. If discharged on leave before the expiry of the two years, if the inebriate relapse he may be secluded for the remainder of the term; if he relapse he may have, if necessary, successive terms of two years' detention. As there is a growing demand for this legislation in Austria, it is expected that the Government measure will be passed into law.

BURIED ALIVE.

WE have received a letter from Mr. Harburt McD. Phillpotts, of Ealing, complaining of the observation in our leader on "The Signs of Death," published on September 28th, that in his published letter to the *Daily Chronicle* he made inadequate acknowledgement of the copious extracts therefrom from Dr. Gower's article on *Insensibility in Quain's Dictionary*, which he wishes us to reproduce. On reading again his letter we retain the same opinion; at the same time we disavow any intention to accuse Mr. Phillpotts of any unworthy motive. We must again observe that although Mr. Phillpotts states in his letter to the *Daily Chronicle* that "we have many instances supported in so thorough and unbiassed a manner" of the burial of living persons, yet he does not mention a single instance.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE TITLE OF "DR."

M.R.C.P. LOND. writes: Will you kindly allow me to sympathize with "Chagrin," who has written a letter to the *BRITISH MEDICAL JOURNAL* under the above heading. "Chagrin," however, must have the consolation of knowing that he has done the right and proper thing in discarding the title "Dr." which his late not very conscientious principal had invested him with. "Chagrin" is also to be commended in obeying the mandate of his College, the Royal College of Physicians of London, which expects all its members to be truthful and honourable. As "Chagrin" now stands he is in unison with the vast majority of the London Practitioners, for I do not know a single member of the College of Physicians who has assumed the title of "Dr." excepting those who have in addition a university degree. This is not the case, however, with the graduates of the Irish and the Edinburgh colleges, who are by no means straitlaced about taking the title "Dr." and M.D., to which they have just as much right as the man in the moon.

LEPROSY IN THE UNITED STATES.

THE New York Correspondent of the *Daily Chronicle* states that the discovery of frequent cases of leprosy in various places in that country has determined a Catholic sisterhood to build a leper hospital at New Orleans. Catherine Carr, of Evansville, Indiana, has bravely offered to act as head nurse, and the Catholic papers are appealing for more volunteers.

AD PASTOREM MEDICUM.

THE following verses appeared in a recent number of the *Westminster Gazette*:

Vulneratus qui rabido canini
Dentibus incisus gellicosus fontes
Spernis invictus sitiens, attingens
Respirans ore,

Quære Pastorem, pœcus atque mirum
Quod colit doctus, genitum ex bacillo;
Cujus infectum rabiem levabit
Mite venenum.

LETTERS, COMMUNICATIONS, ETC., have been received from:

(A) Mr. T. A. Alexander, Watton, Norfolk; Mr. J. Allen, Norwich; J. A. Adams, M.B., Glasgow; Dr. B. Annington, Cambridge; Mr. C. E. Ady, London; Dr. J. Althaus, London; Anglo-Celt. (B) Mr. P. T. B. Beale, London; Mr. W. Blyth, London; H. Barnett, M.B., Church Stretton; Dr. T. Barr, Glasgow; Dr. E. H. Bennett, Dublin; Dr. E. G. Barnes, Epsom; Mr. J. S. Battams, London; Messrs. W. Blizzard and Co., Birmingham; Dr. J. M. Barnett, Belfast; Dr. M. Baines, London; Dr. Braidwood, Amersham; J. B. Bolton, M.B., Oldham; Mr. J. Barber, London; Mr. W. Bassett, Newport. (C) Dr. S. Coupland, London; Mr. W. Cripps, Dulwich; Mr. A. Craske, London; Mr. W. H. Cooke, London; Messrs. Crossley, Mole, and Co., London; Mr. J. Coudrey, Seunthorpe; Messrs. Thos. Christy and Co., London. SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	£0 4 0
Each additional line	0 0 6
A whole column	1 12 8
A page	5 5 0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage-stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

SIXTY-THIRD ANNUAL MEETING

OF THE

BRITISH MEDICAL ASSOCIATION.

Held in LONDON July 30th, 31st, and August 1st, 2nd, 1895.

PROCEEDINGS OF SECTIONS.

SECTION OF OPHTHALMOLOGY.

INTRODUCTORY REMARKS

By HENRY POWER, M.B., F.R.C.S.,

President of the Section.

AFTER the warm expressions of welcome that have been addressed to the members of the congress generally by the President little remains for me to add except that the ophthalmologists of London in a more special manner greet with a friendly grasp of the hand all those who are practising this important department of medicine in other cities and towns of Great Britain or who have come to visit us from other countries. I am sure I am expressing the sentiments of the metropolitan members of this congress when I say that we feel ourselves highly honoured by their presence on this occasion, and that we trust they will not only derive profit from the numerous papers on interesting subjects that have been promised to us, but that they will receive some pleasure from the various objects of interest to be found in this great city and its vicinity. Half a century ago no such friendly salutation could have been offered, because ophthalmology, though full of vitality, had not yet reached the stage of separate existence, but was still merged in general surgery, few or none practising it with exclusiveness.

Within that period, however, great changes have occurred. Affections formerly lightly passed over or altogether disregarded have been found to require for their elucidation prolonged and careful inquiry, and new means and methods of research have been added to our previous stock. The ophthalmoscope invented by Helmholtz, the distinguished physicist and physiologist, whose loss we have had so recently to deplore, opened up a vast field of study, and the revelations obtained by its employment of the changes in the intra-ocular structures is by no means exhausted. The investigation of errors of refraction and their correction in the path pursued by Donders and his school and still further developed by Landolt and others; the study of muscular anomalies and defects, so energetically worked at by our American condisciples; the recognition of the immense practical importance of good colour vision in all forms of land and sea conveyance where the traffic is regulated by coloured signals; the labours of a host of clinical observers both at home and abroad in devising and perfecting methods of treatment both operative and medicinal; the gradual recognition of the fact that many constitutional diseases, as albuminuria, diabetes, leukaemia, and febrile affections generally powerfully influence vision, are all circumstances that have contributed to enlarge the horizon and to develop the resources of the ophthalmologist to an extraordinary degree. This again has led to the establishment of several special hospitals devoted entirely to the treatment of diseases of the eye, and also to the founding of departments with the same object in view in connection with each and all of our general hospitals. To discharge the duties connected with these institutions professors have been appointed, who have required the services of assistants and house surgeons, and these in turn have been able to instruct a large number of intelligent and diligent students, and thus a sound knowledge of the nature and treatment of eye diseases has been diffused throughout the kingdom, so that whereas only a decade or two ago the unfortunate victim of iritis or of keratitis, of squint, cataract, or glaucoma was either compelled to come to one of the great centres of population, at the present time there are few towns even of very moderate size that do not possess either an ophthalmic surgeon or a practitioner capable of

diagnosing and treating any of the ordinary forms of ophthalmic disease.

The foundation of the Ophthalmological Society of Great Britain has proved of the greatest service by enabling remarkable cases to be seen by all who are interested in the subject; by supplying a field where papers can be read in which new views can be advocated, or old ones subjected to wholesome criticism, and in which an *esprit de corps* can be fostered, and a fellow feeling established amongst men who have no petty jealousies, and who seek success only by honourable rivalry.

Our branch of work is by common consent the most fortunate of all in the opportunity it affords of applying methods founded on pure science to the diagnosis and treatment of disease; and so long as our ranks are recruited by those who have gone through the ordinary curriculum of medicine and surgery now required by the examining bodies, and so long as it is recognised by the profession generally that an accurate knowledge of ophthalmology will often supply the key to many constitutional affections, we need have no fear that it will separate itself from the main trunk, or become a barren branch. But this does not the less relieve us from the necessity of constantly keeping in view the scientific side of its study, and I am strongly of opinion that all those who enter the ophthalmic department to pursue it as a special study should have gone through a sound mathematical training. At the present moment this is certainly not a *sine qua non* for a candidate applying for any post at an ophthalmic hospital; but I am sure that if it were made so, it would prove of great advantage to the rising generation of ophthalmologists; that the practical work of correcting errors of refraction would be better done, and that under any circumstances it would be an efficient means of mental training.

Though the organ with which we are engaged is but small, it is yet a theatre large enough to permit many pathological processes to be followed out, which, owing to the diversity of tissues present, are more various, and can be defined with greater precision than elsewhere; and where different modes of treatment can be strictly compared and their relative value estimated. Our diagnosis of disease is daily becoming more precise, as is shown by the circumstance that in 1893 Dr. Hockin, tabulating the statistics of six eye infirmaries, found that out of 30,971 cases of ophthalmic disease, 16,383—or more than half—were cases of conjunctivitis, a large proportion of which would now be distributed under very different heads. No doubt much remains to be done; there are many gaps and imperfections in our knowledge. Let us hope that some of these may be filled up and removed in the labours to which we will now address ourselves.

CASE OF ACROMEGALY WITH OCULAR COMPLICATIONS.

By A. H. BENSON, F.R.C.S.I.

Ophthalmic and Aural Surgeon City of Dublin Hospital.

THE patient was a man, aged 38, who after an injury to his leg nine years before, began to grow lazy, sleepy, and big; the sight had been affected for two or three years. There was no diathesis, either hereditary or acquired. He was a heavy smoker, had a central scotoma for colours, and a bitemporal colour defect. His vision was $\frac{1}{2}$ in each eye. After giving up smoking and taking iodide of potassium, vision was again $\frac{1}{2}$ and remained good for two years. He then took to smoking again, and in two months vision was reduced to $\frac{1}{4}$, at this time he presented the characteristic appearance of acromegaly, and there was irregular bitemporal hemianopsia. Thyroid extract tablets were ordered, but the next day vision was reduced to perception of light; fresh thyroid extract was given, and within seven weeks the vision was again $\frac{1}{2}$. He diminished in weight, and the field of vision had improved.

Dr. Meyer (Paris) mentioned three cases of acromegaly that had come under his observation. One was without ocular symptoms; the other two had diminution of central vision to $\frac{1}{4}$ and $\frac{1}{2}$. Complete temporal hemianopsia, with slight deceleration of the optic discs. In one of the cases the characteristic signs of acromegaly were accompanied by

[1816]

pronounced tabetic symptoms; in the other the general health, with the exception of the acromegaly, was perfect. His patients were still living, but the results of the necropsies that had been made gave very different results; in some the pituitary body was altered, in others not. The most remarkable feature of Mr. Benson's case was the restoration of vision after its nearly absolute abolition.

Dr. SWANZY (Dublin) pointed out that the disease, although only recently described, was not a modern one, inasmuch as marked signs of it were present in the skeleton of the Irish giant Cornelius Magrath, preserved in the museum of Trinity College, Dublin. He lived in the early part of the last century, and it was only about two years ago that a careful examination of the skeleton proved that the giant had been the subject of acromegaly; the sella turcica was so dilated that a small walnut could be placed in it; the groove for the chiasma had disappeared, as also the posterior clinoid processes.

Dr. LITTLE (Manchester) had seen only one case of acromegaly associated with eye symptoms. A gentleman, aged about 30, consulted him about eighteen months ago with failing sight of the left eye of three or four weeks' duration. The vision was equal to $\frac{1}{2}$, refraction normal; optic nerve pale as compared with the other, but that was doubtful. Other eye normal. A month afterwards there was distinct atrophic change in the optic nerve; no neuritis; field contracted upwards and outwards. Two months later there was marked atrophy and vision = Jaeger 20; the right eye was still normal.

Professor PANAS (Paris) said that the case observed by him regarded a woman aged 35, affected with typical acromegaly, preceded by epileptic attacks. The disease was accompanied with hypertrophy of the thyroid gland. The urine contained a large quantity of sugar and albumen. The ocular troubles consisted in bitemporal hemianopsia, the separation line being placed precisely in the middle of the visual field; proof that compression due to the enlargement of the hypophysis, weighed on the posterior angle of the chiasma. He considered that the acromegaly was due in that case to an alteration of the central nervous system, which produced the enlargement of the thyroid gland, and hypophysis, diabetes with albuminuria, and the epileptic attacks at the first stage of the disease.

Professor FUCHS (Vienna) said the central scotoma in Mr. Benson's case might be due not to tobacco amblyopia, but to a connection with the hemiopia. He had seen a case, which was supposed to be a tumour of the intracranial part of one optic nerve, spreading over to the other half of the chiasma. There was complete blindness in one eye, and temporal hemiopia in the other; this hemiopia was preceded by a cerebral scotoma, which disappeared later on, and normal vision was restored. He thought that the scotoma was due to the inflammatory oedema which is so often found in the neighbourhood of the tumour. This oedema might have caused a transient functional trouble in the papillo-macular bundle, which is especially liable to be implicated in pathological conditions of the various kinds.

Dr. HILL GRIFFITH (Manchester) had had for some years a well-marked case, which had recently died under the care of a medical friend, and showed a large sarcomatous tumour of the pituitary body. There was nothing especially of interest in the form of the field defect; like pressure on the chiasma in other conditions, there might be blindness of the eye with temporal hemianopsia for form or only for colour, and so forth. He had also seen one other case under the care of a colleague, and one or two others had been shown him by medical friends.

Mr. SNELL (Sheffield) had seen one case of well-marked acromegaly in a man. There was at that time an absence of eye symptoms; the field of vision for white and colours was normal, and vision was not impaired. The patient had not been examined for twelve or more months, but he was still living. Mr. Benson's case taught the lesson of repeatedly, in such a case, taking the field.

ON INJECTING CHLORINE WATER INTO THE VITREOUS.

Mr. G. A. BERRY (Ophthalmic Surgeon to the Edinburgh Royal Infirmary) gave the results of his further experiments on the injection of chlorine water into the vitreous. His method of operating was to make an incision through the conjunctiva at the equator between the inferior and external recti ten-

dons; a Graefe's knife was then plunged through the denuded sclera. The nozzle of a hypodermic syringe was next introduced into the middle of the vitreous, and 4 minims of freshly-prepared chlorine water slowly injected. The wound was cleaned with chlorine water, and the conjunctiva drawn together by sutures. Moderate chemosis followed the operation, but no other harmful effect. Where purulent infiltration of the vitreous had already set in, the process was aggravated by the injection. He hoped that more experience would prove that these injections of chlorine water would prevent the beginnings of septic inflammations in the eye, especially after the removal of pieces of metal from the eye.

Dr. ARGYLL ROBERTSON had seen most of Mr. Berry's cases, and could corroborate the beneficial effects spoken of; he had employed it in one case in which the result was not satisfactory, owing to the already advanced state of suppuration present.

OPTOMETRY BY THE SUBJECTIVE METHOD.

Dr. G. J. BULL (Paris) believed that the only satisfactory way of testing vision by the subjective method was first to find out the astigmatism before correcting the spherical error. He advocated the method of making the meridian of least refraction emmetropic; any astigmatism then present resolved itself into simple myopic astigmatism.

ESSENTIAL SHRINKING OF THE CONJUNCTIVA.

Mr. C. G. LEE (Honorary Surgeon to the Liverpool Eye and Ear Infirmary) narrated a case in which the vision in both eyes was reduced to a perception of light; the disease in the first eye being complicated with a cyst of the upper lid leading down to bare bone at the margin of the orbit.

CHOROIDAL SARCOMA IN INFANCY.

Mr. JOHN GRIFFITH (Pathologist and Curator Royal Westminster Ophthalmic Hospital) narrated two cases which he considered to be undoubted instances of choroidal sarcoma—one in a child aged 2½ years, in which a section of the eyeball revealed a non-pigmented growth springing from the choroid; in the other, a child aged 4 years, a non-pigmented sarcoma completely filled the eye, and had penetrated through the ciliary region. Mr. Griffith believed sarcoma of the choroid to be more common at this period than was usually admitted; he upheld the view that glioma of the retina was a sarcoma, and objected to the term glioma of the retina.

HEREDITARY CONGENITAL NYSTAGMUS ASSOCIATED WITH HEAD MOVEMENTS.

Mr. ANGUS MACGILLIVRAY (Ophthalmic Surgeon Dundee Royal Infirmary) narrated two series of cases, in one of which the nystagmus could be traced through four generations; the nystagmus was of the horizontal kind, and the head movements persisted throughout life. The affection seemed to be transmitted through females to male children. The movements in these cases seemed to form a connecting link between the infantile cases of head nodding and the tremors found in the aged.

Mr. SNELL (Sheffield) said he did not know that miners' nystagmus could be regarded as hereditary, but he had often found it present in a father and his sons who were also miners. It probably only showed in these cases a tendency to the development of muscular disabilities.

Mr. GWO. WALKER (Liverpool) had found considerable ametropia in several cases of nystagmus in which the movements had been much reduced on correcting the error of refraction. He suggested that the heredity of the nystagmus might depend on the presence of the ametropia.

Mr. LLOYD OWEN (Birmingham) referred to two cases of family nystagmus recorded by him some years ago, in which the nystagmus descended to male children through the females; the only condition common to all members of the family was hypermetropia.

EXHIBITS.

Dr. KOSTER (Utrecht) described and demonstrated the use of his new Tonometer for measuring the tension of the eye.

Professor GAYET (Lyons) showed a series of Photographs illustrating the use of photography in recording the conditions of the eyes before, during, and after treatment.

A NEW THEORY OF ERYTHROPSIA.

Professor FUCHS (Vienna), as the result of his excursions into the snow-covered mountains near Vienna, came to the conclusion that erythropsia is a common occurrence in healthy eyes; he could produce it at will in patients who had had their lenses removed by sending them to walk in the snow. From the result of his experiments he had come to the conclusion that the erythropsia was produced by the visual purple becoming visible during its formation after exhaustion of it in the retina by long exposure to dazzling light.

THE TESTS FOR COLOUR BLINDNESS.

Dr. EDREDGE-GREEN, after giving a summary of the known facts of colour blindness, went on to say that coloured objects of different materials should be used as classification tests, and also coloured lights, modified if necessary by neutral glasses, which altered the colour of the light to the colour blind but not to the normal sighted.

THE INFLUENCE OF THE CEREBRUM AND CEREBELLUM ON EYE MOVEMENTS.

Dr. RISEN RUSSELL, after describing his former work on this subject, went on to say that it was possible to demonstrate even in the dog and cat the existence of distinct foci in the cerebral cortex related to each simple movement of the eyes. With all the external ocular muscles intact the invariable result of excitation of the frontal eye area was the movement of both eyes to the opposite side; when this movement was excluded by dividing the external rectus of the opposite eye and the internal rectus of the eye on the side of the hemisphere stimulated, it became possible to demonstrate the existence of a focus, stimulation of which resulted in simple upward movement of the eyes. Further, after division of the muscles that raised the eye, a focus could be demonstrated, stimulation of which resulted in simple downward movement. Evidence was adduced to show that the true action of these centres in the cortex must be to initiate movement by their action on lower centres. The author went on to describe the effect on movements of the eyes of removing the lateral and middle lobes of the cerebellum.

ERRORS OF REFRACTION IN NEURASTHENIC WOMEN.

Dr. H. MACNAUGHTON JONES read a paper on The Importance of Correcting Errors of Refraction in Neurasthenic Women, in which he stated that of 270 women who had consulted him for affections of their pelvic organs 53 complained of head symptoms. A large proportion of these suffered from varying degrees of hyperopic astigmatism; 27 were completely cured or greatly relieved of their head symptoms by correction of their refractive error.

ON THE QUESTION OF LATENT HYPERMETROPIA IN THE VISUAL EXAMINATION OF CANDIDATES FOR THE PUBLIC SERVICES.

Mr. W. M. BRAUMONT (Bath) in this paper pleaded for more definite regulations with regard to the question of latent hypermetropia in the examination of candidates for the public services.

THE SURGICAL TREATMENT OF DISLOCATION OF THE LENS INTO THE ANTERIOR CHAMBER.

Dr. GEORGE MACKAY (Edinburgh) asked for the experience of his colleagues upon the question of what proportion of cases received permanent benefit from reduction of the dislocation. His own experience was in favour of the employment of a needle to fix and remove the lens from the path of the knife while making the corneal section, and to prevent its falling back into the vitreous whilst the vectis is being passed behind it.

Messrs. PRINSELEY SMITH, DRAKE BROCKMAN, EMERY JONES, and GEO. WALKER narrated their experience.

A NEW OPERATION FOR TRICHIASIS.

Mr. KENNETH SCOTT (Cairo) described the operation which he had performed in its perfect form on 374 cases with invariable success, except in 9 cases where the eyelids had been deformed by previous operation.

EPISCLERITIS PERIODICA FUGAX.

By Professor Dr. ERNST FUCHS,
University of Vienna.

I MEAN by the name "episcleritis periodica fugax" a special form of frequently recurring inflammation of the eye, which attacks pre-eminently the conjunctiva and the episcleral tissue, runs its course without extensive exudation, and is of a very transitory nature. The symptoms of the disease are in many cases so characteristic that we can from the history alone, with great probability, diagnose the same. I think it best to relate some of the special characteristics of the 23 cases which I collected.

I will begin with one of the simplest cases. A man, 34 years of age, had fourteen years ago for the first time an inflammation of the right eye, which lasted eight days. After eight days' interval the left eye became inflamed, likewise for eight days. Up to three years ago the inflammations repeated themselves, always in such a manner that, after intervals of two or three months, sometimes the right eye, sometimes the left, began to be inflamed, and that after a short intermission the other eye followed. Only twice were both eyes affected at the same time. In the last three years the disease has so far become milder that now only one eye becomes inflamed, and after an interval of two or three months the other. The cause of the relapses is unknown to the patient. During the inflammation the pain is insignificant (mostly on moving the eye), but severe photophobia is present, so that the patient during this time is unable to work. The man otherwise is in good health. As I once had the opportunity of observing the inflammation, I found it to consist of a coarse injection of the conjunctiva bulbi, and a particularly severe injection of the episcleral vessels. A sclerotic node was not present.

The following case shows us a patient with gouty predisposition, in whom the travelling of the inflammation was distinctly to be seen, also the partaking of the ciliary body in the hyperæmia. The patient is a man aged 50, wealthy and living well, whose urine on cooling deposits a sediment, which consists of uric acid and oxalate of lime. The amount of uric acid is, in comparison, slightly increased, yet the patient has otherwise no gouty appearance or symptoms. The attacks of inflammation of the eyes have existed for five months; they last usually eight days, and travel from one eye to the other. When I saw the patient the inflammation began in the left eye on the outer side of the cornea, jumped from there to the inner side of the same eye, and then over to the right eye, where it first attacked the outer side of the eyeball. In the meantime the left eye had again assumed its normal pale appearance. The inflammation consists in a coarse net-like injection of the conjunctiva and a very intense injection of the underlying ciliary and episcleral vessels. The non-inflamed parts of the eyeball were perfectly pale, especially the conjunctiva of the fornix and of the lids. Pain was present with movement of the eye, and on accommodation. It was probably as the result of these pains that I found during the attack that the near point was removed about 40 centimetres away, while during the intervals of freedom from an attack it was 25 centimetres. The refraction and acuteness of vision remained unchanged.

It more frequently happens, however, that the hyperæmia of the ciliary body leads to a spasm of accommodation, and therefore to an apparent myopia. This will be illustrated in the following case, which is, moreover, interesting on this account, that there comes here into play not the uratic diathesis, but intermittent fever as the cause of the disease. The patient is 31 years of age, and a labourer. He declares that in other respects he is perfectly healthy, and knows nothing of having passed through a fever. The internal examination showed, however, a rather significant enlargement of the spleen. The patient has suffered since the year 1882 from inflammations, which alternately attack both eyes. The attacks occur every two or three weeks, and lasted in the

beginning only one to two days, later four to five, or even eight, days; and while at first the eye during the attack was only reddened and not painful, there were present later severe pains, which radiated to the forehead, nose, and ear. The inflamed eye is also extremely sensitive to the touch. During the attack the patient sees as through a mist; he has also fever and great thirst. The patient showed himself for two years from time to time in the clinic, and was observed during several attacks. The inflamed eye showed conjunctival and ciliary injection, but was otherwise of normal appearance. Only the vision was diminished, and myopia was present. This varied according to the severity of the attack, amounting during the inflammation to 8 dioptres; the vision was thereby reduced to $\frac{1}{2}$. During the time of freedom from inflammation there was present emmetropia and vision $\frac{1}{2}$. The treatment consisted in quinine, which did not abort the attack, but when the patient had taken quinine for a long time the attacks did not occur, so that there were intervals of two to three months. But as the patient always ceased to take the quinine on account of the expense, the attack soon returned.

The involvement of the deeper parts in the inflammation expressed itself also in the fact that the pains often become especially prominent with movement of the eye. Many patients can predict the onset of the attack in that by fixation of the finger held before the eye they experience pain in consequence of the accommodation and convergence. The inflammatory oedema can extend so far posteriorly that even exophthalmos arises.

It is quite frequent for the inflammation to be associated with a similar affection of the mucous membrane of the nose, and the inflammation of the eye frequently begins with a severe nasal catarrh; the predisposing cause of these attacks seems to be a cold.

The following case is a fair example of this kind; it also goes to show that the presence of a uratic diathesis need not necessarily be the cause of the inflammation of the eye. A man, 46 years of age, the owner of a large estate, has been since the year 1887 exceedingly sensitive to change of temperature. As soon as he exposes himself to such he acquires a severe acute nasal catarrh and inflammation of the eye.

In the first years he was so sensitive, that the mere taking hold of the cold doorknob, or the resting of his elbow on a marble plate was sufficient to make him sneeze thirty times in succession, and an acute nasal catarrh and inflammation of the eye soon followed. Also later, when the sensitiveness had diminished, it was sufficient to go out of a warm room into a cold one for these symptoms to appear. The patient is bald-headed, and a mere draught on his bald head is especially apt to produce the disease. Otherwise he can in all weathers, summer and winter, remain outdoors on his estate, become heated or drenched, without catching cold. The examination of the nose showed a considerable thickening of the nasal mucous membrane, especially the lower turbinates. These were repeatedly cauterised with the galvanocautery, after which an improvement followed, which, however, was of short duration. The inflammation of the eye consisted in a severe reddening of the whole conjunctiva, especially the conjunctiva bulbi, which as a rule disappeared after twenty-four hours. The patient lives well, is well nourished, and has some increase of uric acid in his urine; otherwise no gouty symptoms are present. All attempts at a cure proved unsuccessful, until he had, in the summer, 1894, the left upper canine tooth extracted. This tooth, the patient asserted, only appeared when he was 30 years old, and had come out of the gum posteriorly to the normal row of teeth; it had an unusually long root, but was otherwise healthy. Since the extraction of this tooth all these symptoms, even the sensitiveness to change of temperature, have disappeared completely.

I will not, gentlemen, take up your time any longer with histories of other cases, of which I could mention a considerable number. Those related by me are the most frequent types of the affection. The disease in question consists in a severe inflammation of the conjunctiva bulbi, but especially of the underlying scleral tissue. From acute conjunctival catarrh it differs essentially by the absence of secretion and by localising itself on the conjunctiva bulbi, of which at least only one quadrant is affected. From the nasal epiphora it is distinguished by the absence of any nodes

and its very rapid disappearance, after which no traces of the disease are to be found. It consists chiefly in a severe inflammatory oedema of the episcleral tissue; the deeper structures often take part in the hyperemia, as is shown sometimes by the presence of pains on accommodation, or movements of the eyeball, or spasm of the sphincter of the pupil which causes miosis, or a spasm of the ciliary muscle which produces transient myopia. The inflammation is frequently accompanied by severe photophobia, lachrymation, and pains; the latter often make their appearance before the inflammation, and denote its coming.

The duration of the inflammation is as a rule only a few days. The inflammations reappear at regular intervals, which last from several weeks to a few months. In the same case the disease may vary in its course, so that the attacks become more frequent and severe or, on the contrary, less frequent and milder. The duration of the disease is as a rule some years. After inquiry I find that only 7 of my 23 patients are now entirely cured; in one of these cases, however, the disease had lasted twenty years. The treatment in most cases of episcleritis fugax is powerless, as the long duration of the disease shows. With a diet suited for the uratic diathesis or with hydrotherapy one can at times produce an improvement, so far that the disease returns less often and gets milder. But more effective are quinine and salicylate of soda, each of these remedies having produced a complete and lasting cure in its case.

Episcleritis fugax is a rare disease; still I am sure that most of you have observed such cases. In fact the first two accurate descriptions which I find in the literature are given by English authors—namely, by Mr. Hutchinson and Mr. Nettleship. Mr. Hutchinson described this disease in his Bowman Lecture (1884) as a "hot eye." Mr. Nettleship also reported such cases before the Ophthalmological Society in 1888. Both gentlemen believe that the disease is similar to recurrent iritis, and eventually may pass into it, which, I must confess, I have never observed, even in the longest duration of the disease. I find that another case of this affection has been reported by Mr. Swan Barnett in 1892, who considers it as a vasomotor disturbance.

I have observed the disease most frequently in men of middle age, less often in women. Mr. Hutchinson and Mr. Nettleship claim gout to be the cause of the same. It is true that some of my patients are living in the best of circumstances, and that they excrete probably more uric acid than normal; however, they exhibited no pronounced gouty symptoms, and besides I must mention that typical gout is extremely rare in Austria. There were decided signs of rheumatism present only in one patient, who has had two attacks of acute rheumatism of the joints previous to his eye disease; instead there were indications of malaria in several cases. Although the patients had had no typical attacks of intermittent fever, still there was enlargement of the spleen present in a few cases, and in these as well as others quinine produced good effect. This drug was able to shorten an attack, or, when taken for a long time, prolong the intervals of freedom. In one case there was an immediate and entirely curative effect produced by the quinine. One must, however, not confuse the episcleritis fugax with a certain conjunctivitis, which was observed in cases of intermittent fever, with each attack or in place of the fever.

I must confess that for the large number of my cases no etiology could be found. I believe that the predisposition to this disease is caused by an abnormality of nutrition, such as gouty diathesis, malaria, and so forth. In consequence of the general disturbance, an accumulation of noxious substances takes place, which, when a sufficient amount is collected, would produce an attack of inflammation. The last provocation to such an attack is often produced by some external cause such as change of temperature.

I thought I would first consider the disease as a vasomotor disturbance or of an angioneurotic nature, somewhat like urticaria, because one of my last cases was accompanied with urticaria. By the collection and investigation of the histories of my patients I assured myself, however, that the episcleritis differentiates itself from the angioneurotic affections; that the symptoms far exceed the simple non-inflammatory oedema; and that the attacks are of longer duration than is known of the vasomotor neurosis. As a vasomotor affection,

I would like to consider transitory oedema of the lids which I have observed myself in several cases, and of which a large number of cases have been reported by others, also by English authors, as Mr. Ormerod, Mr. Jamieson, Mr. Doyné, Mr. Gunn, Mr. Collins, and others.

Mr. BERRY (Edinburgh) believed that this disease was known to all ophthalmologists, though probably under different names. It was probably the same disease as that described by v. Graefe, under the term "subconjunctivitis." It was not a conjunctivitis, as the secretion was not increased. It was possibly in some cases the prodroma of something more severe—iridocyclitis or scleritis.

Dr. FURYS JONES (Manchester) had had three cases of this disease, which agreed entirely with Professor Fuchs's account of it. One of them was very obstinate, and resisted all kinds of treatment, both local and general, for more than a year; he at last performed peritomy with great and lasting benefit. He had since done peritomy in the other two cases, with marked benefit.

Mr. PRIESTLEY SMITH (Birmingham) thought the affection a difficult one to define. It was probably allied with episcleritis, with urticaria, with hay fever and herpes. In addition to the local cause there was often a systemic cause present as well—gout, rheumatism, or faulty elimination of some kind. He advocated systematic drinking of hot water in the morning and at night, as useful in eliminating waste products and removing the tendency to congestive states.

Mr. CUTHBERT thought these cases were probably of rheumatic origin. He found great benefit resulted from salicin and quinine, hot water internally and lamp baths.

A DISCUSSION ON THE DIAGNOSIS OF ORBITAL TUMOURS.

L.—H. R. SWANZY, F.R.C.S.I.,
Dublin.

IN the diagnosis of an orbital tumour there are three questions which present themselves—first, the main question, Is a tumour of the orbit present?; secondly, Is the new growth confined to the orbit, or does it extend to neighbouring cavities? and, thirdly, Of what kind is the new growth? The diagnosis as regards any of these points does not often occasion much difficulty in advanced stages of the disease, especially where the growth occupies the anterior part of the orbit or protrudes from it. It is rather in the early and middle stages that difficulties in diagnosis are apt to present themselves, and in this paper attention will be mainly directed to those stages. It is not intended to indicate within the scope of this paper the diagnosis of some extremely rare tumours of the orbit, such as cysticercus, plexiform neuroma, and so on.

Of the signs by which the presence of a tumour is diagnosed in its early stages by far the most important, because the most constant, is exophthalmos. In the earliest stages of a growth which commences in the deepest part of the orbit, there may be, it is true, no exophthalmos, while other symptoms—defects of sight, pain, loss of motion—may already be present, but when the growth attains to certain dimensions, or if, in the anterior part of the orbit, there be even a small tumour, the eyeball must be pushed out of its place.

It is not necessary that I should enumerate all the other causes of exophthalmos, but assuming that they have as far as possible been excluded, exorbitism at once renders the presence of an orbital tumour almost a certainty. An important diagnostic point in connection with the exophthalmos caused by a tumour is that its direction is almost always oblique and not straight forwards, for orbital tumours commonly tend to develop more along some one wall of the orbit than along the others, and hence the eyeball becomes pushed towards the opposite side as well as forward. In cellulitis, oedema of the orbital tissues, Graves's disease, and paralytic proptosis the exophthalmos has a direction straight forwards. Tumours growing from the apex of the orbit may in their early stages cause no obliquity of direction in the displacement of the globe, and some tumours do not do so even in an advanced stage of their growth, but these cases are ex-

ceptional. Tumours too, situated altogether within the muscular cone, of which the most common are tumours of the optic nerve, need not cause any lateral displacement of the globe. Again, the exophthalmos caused by an orbital tumour usually increases in degree slowly and gradually, differing in this respect from exophthalmos due to most of the other causes, in which either a sudden or a rapid development of the exorbitism is the rule. While tumours are sometimes present in both orbits, especially lymphoma or lymphosarcoma, yet it is infinitely more common for one orbit alone to be diseased, and hence monolateral exophthalmos is suggestive of orbital tumour.

Although exorbitism is almost an essential, and other causes being excluded, so conclusive a sign, yet we naturally seek for additional aids in a diagnosis of such grave importance. Of these the most valuable is often obtained by palpation of the orbit, provided that the new growth has come within reach in the anterior part of the cavity. In many cases, indeed, there is no difficulty whatever in recognising the presence of an orbital tumour by this means, the sensation obtainable by the tip of the finger pressed into the orbit being very definite, but in other cases the evidence is not so clear, and the surgeon may have a reasonable doubt as to whether there is any abnormal resistance met with by the tip of his finger. By palpation, too, we may gain some knowledge of the position, extent, shape, and consistence of the tumour, and whether it be adherent either to the walls of the orbit or to the eyeball. It is important, when practicable, to compare the result of examination of the diseased orbit with the condition of the sound orbit, and this can be done to greater advantage if palpation of the orbits be performed simultaneously with a finger of each hand.

Derangements of vision are often, but by no means always, present in the early and middle stages of the growth of an orbital tumour. Their occurrence depends frequently on the rapidity of the growth of the tumour rather than upon its size. In an early stage of a rapidly increasing tumour the sudden stretching of and pressure on the optic nerve may produce absolute blindness, while in another case, with an equal degree of exorbitism, but which has been brought on by a slowly growing tumour, vision may be unaffected by reason of the optic nerve becoming gradually accustomed to the change. Yet slowly growing tumours, which spring from the optic nerve or its neighbourhood, or from the deepest part of the orbit, are competent, by direct pressure on, or by implication of the optic nerve, to cause serious loss of sight, even in an early stage, and with but little exophthalmos. Optic neuritis, and, later on, atrophy, are occasionally discovered with the ophthalmoscope. Diplopia is often present when the globe is at first displaced, but disappears when the exophthalmos becomes extreme or the vision defective.

Pain is a symptom sometimes, but by no means always, present in cases of orbital tumours. It is especially liable to be complained of when the growth is increasing rapidly in size, even though it may not have attained to great dimensions. The pain is then often of a neuralgic kind, and very severe, from the unaccustomed pressure on branches of the fifth nerve in the orbit. Certain sorts of tumour are more liable to be attended by pain than others, and the nature of the pain, too, is to some extent characteristic of the sort of new growth. To this I shall have to refer later on.

Loss of power of motion of the eyeball is a very common symptom in cases of orbital tumours. It is caused in some cases by the mechanical obstruction offered by the tumour, as a result of which motion of the eyeball towards the side of the orbit on which the new growth is situated becomes defective. In other cases the loss of motion is caused by stretching of the muscles from the exophthalmos, or by implication of them in the new growth, or by atrophy of the tissues, or by paralysis of the ocular nerves from pressure. When there is little or no loss of motion, while the exorbitism is marked, the conclusion may be drawn that the tumour lies within the muscular cone.

As regards the question whether the tumour is confined to the orbit, or involves one or more of the neighbouring cavities, it may be assumed that it is confined to the orbit, unless there are symptoms or signs which point in the contrary direction, and in each case these symptoms and signs ought to be looked for. Tumours may either originate in one of

these spaces and grow into the orbit, which is the more common event; or, originating in the orbit, they may at a later stage spread to a neighbouring space; and it is often the history or progress of the case alone that can inform us which of these events has taken place.

Tumours which originate in the frontal sinus are usually either mucocele or osteoma. Mucocele of the frontal sinus frequently extends to the ethmoidal sinus and thence first encroaches on the orbit, pushing the eyeball downwards and outwards. Sometimes there is supraorbital pain, and sometimes, when the nasal meatus has become involved, there is discharge from the nostril. The diagnosis in these cases is often obscure. Osteoma of the frontal sinus shows itself as a slowly-growing and densely-hard tumour almost free from pain, situated along the superior margin of the orbit, extending into the latter and pushing the eyeball downwards and forwards. It may subsequently extend to the orbital plate of the ethmoid. An error in diagnosis is, I think, liable to be made, sometimes when a tumour of the frontal sinus drives the outer table downwards and forwards, and when the latter gives to the touch the sensation of a bony growth. If the tumour also involves the ethmoid cells, the lachrymal bone is apt to be driven forwards, and the liability to the error I have mentioned is further increased. This was well exemplified in a case recently under the care of my friend Mr. Kendal Franks, where a sarcoma originating in the ethmoid cells had invaded the frontal sinus and the orbit, causing marked exophthalmos, yet no soft tumour could be felt in the orbit owing to the displacement forwards of the lachrymal bone, and downwards and forwards of the roof of the orbit, a condition which at first sight suggested the presence of an osteoma of the orbit. Bony growths originating in the orbit may invade the frontal sinus, and, whether originating there or in the sinus, are liable to produce absorption of the tables of the skull without any cerebral symptoms to indicate the occurrence.

Tumours of the ethmoid cells which encroach upon the orbit are likewise most commonly either mucocele or osteoma. Mucocele of the ethmoid cells presents itself in the orbit as a tumour gradually increasing in size on the inner wall of the orbit, and pushing the eyeball outwards and forwards. When it has grown sufficiently large, palpation of it will discover fluctuation. The source of error just now referred to, when the lachrymal bone is pushed in front of a slowly-growing tumour of the ethmoid cells, must be borne in mind. The sharp posterolore of the lachrymal bone is easily felt for and found, and will direct the diagnosis into the right channel. Mucocele of the ethmoid cells encroaching on the orbit must also be distinguished from a dermoid cyst, but to this I shall return later on. Osteoma of the ethmoid appears in the orbit as a hard round swelling at the inner canthus followed by a swelling of the cheek and displacement of the eye outwards and forwards. It is apt also to extend into the nasal meatus, driving the septum out of place, and to push the hard palate downwards, so that examinations of the nose and of the mouth should be made in aid of the diagnosis. Enchondromata and fibromata also sometimes spring from the ethmoid and extend into the orbit, and malignant growths may be met with here.

Tumours that spring from the body of the sphenoid bone, or from the antrum of the sphenoid, and encroach upon the orbit are rare, and the diagnosis of their origin in an early stage is practically impossible. Here, again, the examination of the naso-pharynx is important. It is stated (Stedman Bull) that an orbital tumour—which soon causes blindness, commencing in the temporal side of the field, and leaving the fixation point unaffected to the last, while at the same time a growth appears in naso-pharynx—is likely to be one having its origin in the sphenoid antrum. Bony tumours—osteoma, hyperostosis, and exostosis—polypi, and sarcomata are the growths most frequently found to originate in the sphenoid antrum.

Tumours of the maxillary antrum sometimes erode the floor of the orbit and grow into that cavity, driving the eyeball upwards and inwards, or upwards and outwards. The breadth of the cheek is increased, the nose becomes pushed towards the opposite side, and the roof of the mouth is pushed downwards. Tumours of the antrum of Highmore sometimes cause pain in the teeth or in the region of the dis-

tribution of the infraorbital nerve, and there may be a dull pain in the region of the antrum. In some cases there is a discharge of pus or of blood from the nostril.

Tumours of the brain do not often invade the orbit, and then it is tumours of the middle fossa which gain access through the sphenoid fissure and optic foramen. The diagnosis of the origin of the disease can only be made if cerebral symptoms have existed prior to any sign of a new growth in the orbit. Tumours of the pituitary body may encroach upon the orbit by way of the sphenoid fissure and are apt to be associated with polyuria and bitemporal hemianopsia, which serve to aid the diagnosis. A more common event, although not in an early stage of the growth, is the extension of a primary orbital tumour to the brain, either along the optic nerve, through the sphenoid fissure, or through the roof of the orbit by erosion of the bone. This occurrence is usually evidenced by the presence of cerebral symptoms, but cases have been met with where no such symptoms existed, although the orbital growth had encroached upon the anterior or middle fossa of the skull.

As regards the nature of the growth which may be present, it must be admitted that, in many instances, in the early stages of a deeply seated tumour we have to rest content with an indefinite or provisional diagnosis, unless an exploratory operation, with puncture or harpooning of the mass, is practicable, and such a procedure is often called for, in order to decide not only the nature of the tumour but also its extent and origin. Yet there are symptoms which with caution may be utilised in this branch of the diagnosis, namely, pain, marked loss of motion, pulsation, consistency, and congenital origin.

Although pain is frequently present along with orbital growths of every sort, freedom from pain of a very severe kind is much more common with benign than with malignant tumours, in which latter it is often complained of even from an early stage.

Loss of motion of the eyeball of some degree will be found with nearly every orbital tumour, especially towards the side of the tumour, but marked loss of motion in every direction, or in nearly every direction, while the tumour may not as yet have attained a large size, is a sign very suggestive of a malignant tumour. In a case which was quite recently under my care there was complete loss of power of the third and sixth pairs, the exorbitism was directly forwards and of moderate degree, and a soft new growth could be indistinctly felt with the finger on the floor of the orbit. After removal the great mass of the tumour was shown to be fat and dense connective tissue, but towards the centre of this mass was situated a small pigmented round-celled sarcoma. There was no pain in this case, and in that particular it proved to be an exception to the general rule in malignant tumours.

Pulsation of the growth, or of the eyeball which is pushed out of place by it, points to its being one or other of certain vascular tumours in the orbit, or, which is more common, in the middle fossa of the skull. In addition to this, in these cases we expect to find characteristic bruits, which are perceptible both subjectively to the patient and objectively to the surgeon on auscultation of the orbit and skull, and there may also be a fremitus observable on placing the hand over the eyeball. But it must be borne in mind that pulsation may sometimes be found with malignant tumours which are rich in vessels, and with non-vascular tumours situated deeply in the orbit.

If a tumour be congenital, this as a rule points to its being either an encephalocele or a dermoid cyst. Dermoid cysts, although always congenital, do not often grow to any size until the age of puberty or later, and may then for the first time give rise to troublesome symptoms. An encephalocele is situated most commonly in the inner angle of the orbit, and is a striking object from the moment of birth. It is a fluctuating, semi-transparent, pulsating tumour, which disappears on pressure while cerebral symptoms are simultaneously produced. Occasionally an encephalocele becomes shut off from the cranial cavity so as to form a true cyst. Pressure on it does not then cause any cerebral disturbance, and the diagnosis may be less certain.

The consistence of a tumour is a valuable guide to its nature. All the bony tumours present, of course, the sensation of dense hardness to the touch, but there are some

malignant growths of such hardness that it may not be easy to tell them from the osteomata by palpation, and an exploratory puncture becomes necessary in order to decide the point. The growth of an orbital osteoma is excessively slow, and pain is rare. In addition to the dense hardness of these tumours, their usually globular and somewhat nodulated surface, their immobility and their direct connection with the walls of the orbit ascertainable by touch, are the deciding points in the diagnosis. Certain malignant growths are so soft that false fluctuation may be obtained from them, and the erroneous diagnosis of a cyst or abscess be made, and here too an exploratory operation is in its place. True fluctuation suggests the presence of a cyst, usually a dermoid cyst, a meningocele, a mucocele proceeding from the ethmoid sinus, an abscess, or very rarely an echinococcus cyst or a cysticercus. The echinococcus cysts are usually associated with severe ciliary neuralgia. To obtain fluctuation, the best method is, with the tips of all the fingers of one hand placed on the protruded eyeball, to push it suddenly backwards towards its normal position, while at the same time with the tip of the first or first and second finger of the other hand on the tumour the impact of the displaced fluid contents of the tumour is observed. It is as a rule less satisfactory to endeavour with one or two fingers of each hand placed on the tumour to obtain fluctuation, for the surface which can be reached is usually small, and, moreover, the force of the pressure made on it is transferred largely to the eyeball and other movable contents of the orbit, and, consequently, the strength of the impact on the finger of the other hand is reduced. Cysts, it should be remembered, are sometimes associated with both bony and malignant tumours, and may mask the main disease, which is not discovered until operative means are being used for removal of the cyst. Some dermoid cysts, the cholesteatomata, do not afford any fluctuation.

In respect of the diagnosis of sarcoma of the orbit in its many varieties, it has been stated by a distinguished writer (Berzin) on this subject, that "When we meet with a solid tumour with nodulated surface, which does not fluctuate, does not pulsate, is not compressible nor densely hard, does not seem to be in connection with the brain, and does not proceed from the eyelids, eyeball, lachrymal gland, optic nerve, or neighbouring cavities, we may conclude that we have to do with a sarcoma of the orbit." Yet here we are liable to errors, for many very vascular sarcomata are compressible and may exhibit pulsation, while myxosarcomata and cysto-sarcomata sometimes fluctuate.

Nævus of the orbit is almost always associated with nævus of the eyelids. It is soft and somewhat compressible. The tumour swells and the exorbitism increases, if the head be held forward, or if congestion of the vessels of the head be produced in any other manner. The motions of the eyeball are much impeded, and pain is rarely complained of. These tumours are congenital.

Tumours of the optic nerve, as von Graefe pointed out, are diagnosed by the protrusion of the globe being pretty much in the direction of the visual axis, with retention of the mobility of the eyeball, and of the normal centre of motion. The consistence of the tumour is soft, there is absence of pain, and in an early stage loss of sight. The increase in size of the tumour is usually slow. Palpation under chloroform may discover a tumour which is in connection with the eyeball behind, and which extends back towards the optic foramen. The diagnosis of tumours of the lachrymal gland is mainly made from the position of the growth, and the direction of the dislocation of the globe produced by it.

In conclusion, it must be admitted that the diagnosis of orbital tumours, especially in respect of their nature and extent, and as to whether neighbouring cavities are involved, must in many instances remain uncertain, until in the course of the operative measures undertaken for their removal the true state of things has been exposed.

II. PROFESSOR PANAS, M.D.,

Paris.

PERIODIC EMBRYANT TUMOURS OF THE ORBIT.

When we look into the annals of science we are struck by finding a number of observations of exorbitism with tumour

supposed to be malignant, in which the appearance of an intercurrent erysipelas or a medical treatment employed intentionally, or by chance, has had the effect of causing the disappearance of the tumour. We nearly always infer, and often wrongly, that the case was one of orbital syphiloma. Inasmuch as syphilis stands at the head of infectious diseases, it is certainly very often the cause, but as mercury and iodide of potassium have a marked action on other things besides syphiloma, we are not justified in inferring the existence of syphilis, by reason of the happy effect of treatment, unless there be other specific manifestations. Such unjustifiable inferences are still constantly repeated, as we may see by looking over the works that have appeared recently, among others those of Maracek,¹ Campana,² Galezowski,³ Haltenhoff,⁴ W. H. Hennebert and Coppez.⁵

In this last work the opinion as to the syphilitic nature is based upon the cure by the mixed treatment, and upon the existence of pharyngo-nasal cicatrices only, as are observed in cases of old osseous outgrowths of all syphilitic contamination.

The recent communication of Karmarch in the German Society of Surgery, 1895, does not appear to be exempt from valid objections. The author enumerates cases of sarcomas and lymphadenomas of syphilitic origin having yielded to the specific treatment. He cites no fewer than forty cases—quite a great number. He thinks that the diathesis can be acquired or inherited. The cranium is the seat of predilection, and there is rapid recurrence of the tumour after extirpation. The tumours in question give way on the contrary to the treatment by iodide of potassium, to the action of toxins, and upon the appearance of an intercurrent erysipelas. The histological examination of the neoplasm, showing the presence of granular tissue with patches of fatty degeneration and proliferation of the vascular walls, would have, according to him, a great diagnostic value.

This manner of interpreting the clinical facts, which is also the one admitted by Krause,⁶ of Altona, with regard to analogous tumours—among others one of the nasal fossa cured by iodide of potassium, of some value a few years ago—does not hold good, since we are beginning to recognise that a whole category of tumours reputed malignant are distinctly independent of syphilis. We think that a number of neoplasms thought to be lymphomas, sarcomas, or syphilomas ought to be attributed to the dyscrasia produced by some toxins.

The infectious principles, microbes or toxins, act by means of the venous anastomoses and by the lymphatics, or after their penetration into the entire organism. According to this there would be quite a class of infectious tumours, the syphilitic being an example, but not the only one. From considerations of this order we were led to look upon the neoplasms of the orbit, especially the symmetrical ones, in a new light, and that by clinical observation. The starting point was that of a patient whose history was related in one of my clinical lectures at the Hôtel Dieu.⁷ He presented a double exophthalmia, simulating in all respects sarcoma, which was completely cured by the arsenical treatment in solution in the form of arseniate of soda. Iodide of potassium, on the other hand, administered by a colleague, had for effect to exaggerate the volume of the tumour, as also the exorbitism. The patient, a vigorous man of 35 years, was absolutely exempt from all syphilitic taint, but had been suffering for some years from a certain degree of *exophthalmia* accompanied by epistaxis. To explain the double exophthalmia with fixity of the eyeball, papillary stasis, and waxy chemotic ectropion of the lids we admitted a microbial infection of the cellular tissue of the orbit caused by the microbes of osseous from the nasal fossa.

We asked ourselves whether cases of this order were not more frequent than is generally thought. An interesting fact to note was that the two tumours of firm consistence, had for principal seat the inner or nasal wall of the two orbits, causing bilateral divergent squint. Since that time we have been able to observe a young woman, not syphilitic,

but affected with sarcomatous polypi of the left nasal fossa. These polypi having been several times removed, an exophthalmia manifested itself in the left eye with marked external strabismus, and the operation demonstrated that there was no sarcoma of the orbit, but that the cellular tissue was indurated, with destruction of the corresponding lateral masses of the ethmoid. On the other hand, histological examination of a fragment of the nasal polypi showed that these were composed of pure adenoid tissue in no way sarcomatous.

To explain what had occurred in the orbit we admitted that at a given time the repeated removal of the nasal polypi must have been accompanied by an infectious process which propagated itself towards the cavity of the orbit. Upon this supposition the patient was put upon an arsenical treatment, which ameliorated her condition and has preserved up to the present time the vision of the exorbitic eye.

Apropos of such interesting facts, we had the good fortune to confer with Professor Duplay and our colleague in surgery, Schwartz, and both related to us what follows: In the presence of a neoplasm of the two superior maxillary bones, occurring in a boy aged 15, well constituted and exempt from syphilis, either acquired or inherited, Dr. Schwartz, in consideration of the bilaterality of what he thought to be a sarcoma and the young age of the patient, tried, before proceeding to the operation, the internal treatment with Fowler's solution. At the end of some weeks, the tumours were completely resorbed, proving that they were not of a malignant nature.

The case of Professor Duplay concerns an adult Brazilian with a voluminous tumour of the iliac fossa presenting all the characters of pelvi-abdominal sarcoma adherent to the bone. Judging the case to be an incurable one, he prescribed the tincture of conium as a "moral medication," and to allay the pain. What was his astonishment to learn three or four months later from the patient's physician that under the influence of the conium, an old remedy reputed as efficacious and praised by Trousseau, the tumour had entirely disappeared.

Quite recently we were called in consultation with Professor Grancher by Dr. Kalt, to see a girl aged 10, well constituted and absolutely exempt from all syphilitic antecedents, either personal or hereditary. There had been noticed in April, 1895, a soft tumour the size of a small nut, at the superior and internal angle of the right orbit behind the lachrymal sac. This tumour, preceded by pain in the frontal region, was adherent to the bone by a large base, and also to the internal rectus muscle, and offered the reactionary signs of an abscess. Dr. Kalt made an incision into it on the fourth day, which proved to him that the mass had the constitution of a neoplasm. Upon the examination of a small fragment which he had removed, he found it under the microscope to be composed of round cells recalling those of sarcoma. In spite of this constitution, and apart from all syphilitic manifestations, mercurial ointment and the internal treatment by the iodide of potassium were prescribed by common accord. Six weeks later the so-called sarcoma had been nearly completely absorbed. A peculiarity to note was that at the outset of the evolution of the tumour there had been for one day a flow of pus from the corresponding nostril. As the frontal sinus is hardly formed at the age of the patient (10 years), we wondered whether the case was not one of a point of ethmoidal labyrinthitis having caused the engorgement by infection of the adjoining portion of the periosteum and of the cellular tissue of the orbit which had been infiltrated with migratory cells. It is not astonishing then that the resorption was caused by the influence of iodide of potassium combined with mercury, and we need not attribute the effect on that account to a specific cause of which no trace could be found.

In the presence of cases of that order we recalled to memory those published by others under different titles with reference to the orbit. Who does not know of the celebrated case of General Radetzky, related in the treatise of Mackenzie, where a chronic indurated abscess of the orbit was taken by the ophthalmological celebrities of that time for a malignant tumour, and which ended in a spontaneous cure? We ourselves have observed a case of the same order in the service of Velpeau, who had been mistaken in his diagnosis up to the time when the patient, a youth aged 14, was cured after

evacuation of the pus. A deep exploratory puncture with the bistoury having proved negative had confirmed Velpeau in his error, which lasted more than three months. Professor Gayet¹ observed the case of a man aged 70 affected with a double exophthalmia without any known cause. He thought that the symmetrical tumour of the two orbits should be considered one of lymphadenitis. Having made bibliographical researches, he thought to class his case with those published by Arnold, O. Becker, Leber, Reymond of Turin, and Ostwald. Delens also published in the *Archives d'Ophthalmologie*, 1886, a double orbital lymphadenoma which disappeared during an attack of cholera.

The question whether lymphadenoma could be regarded as of infectious origin appeared to us the more certain, for the reason that we had under our care a young patient affected with lymphosarcoma of the pharynx, occurring after an attempt by a colleague to remove adenoid vegetations from the nasal pharynx. That presumption became a certainty since P. Delbet made his communication on the experimental inoculability of lymphadenoma.² On account of the importance of that work we beg permission to give a summary of it.

The proof of the infectious nature of lymphadenoma is based on the reproduction of the affection from man to the dog by inoculation of pure cultures of a particular bacillus. It was a question of a woman with generalised lymphadenoma of the specially splenic form.

Having made cultures with the blood taken from the spleen with a Pravaz syringe, the experimenter inoculated dogs with massive doses of the pure colonies at varying intervals. The only dog that he sacrificed had been inoculated on May 16th, then on the 18th, and so on until June 15th when he was killed; half the injection had been made in the peritoneum, half in the cellular tissue. The animal having lost 9 kilos, began to diminish in weight at the rate of 2 kilos in a fortnight. At the necropsy the glands of the mesentery, of the mesocolon, the thoracic and the prevertebral glands, those of the right groin and of the axillary spaces were considerably hypertrophied. To be free from the objection that the polyadenitis might not be in any way specific, he made cultures with the glands of the dog, and he was able to ascertain the presence of the inoculated bacillus in a pure state, while it was not to be found in the blood of the animal. Delbet promises to publish a paper later on the complete biological study of the bacillus causing lymphadenoma.

Besides the tumours of the orbit, sometimes unilateral, at other times bilateral, those having the lachrymal glands for their primitive seat must be noted. There are several varieties caused by general infectious conditions, such as gonorrhoea, the eruptive fevers, influenza, mumps, and perhaps also syphilis. Their peculiarity is that they are bilateral, and are accompanied with engorgement of the parotid and submaxillary glands. In a certain number of cases, as in that of one of our patients, the starting point had been some uterine trouble at the menopause, complicated with hæmorrhages from a fibromyoma of the uterus. We think that we have to do here with an infectious state of the organism, as after the engorgement of the lachrymal glands our patient presented a double plastic choroiditis. We have published quite an interesting case in the *Semaine Médicale*, June 23rd, 1895. The case was one of acute dacryoadenitis in an adult. In looking for a possible infection we were led to discover that there existed a tonsillitis; one of the tonsils yet swollen and secreting furnished a pus full of streptococci.

We all remember the interesting case cited by Eales and Jonathan Hutchinson,³ in which the cure was obtained by iodide of potassium. The patient of the last-named author was an inhabitant of Calcutta who had come to London with his eyes exorbitic due to the swelling of the lachrymal glands. The parotid and cervical glands were also swollen.

From the facts and reflections contained in this paper let me be permitted to draw a certain number of deductions. If they are not as yet very conclusive, they will have the advantage at least of fixing the attention of clinicians and will be, I hope, profitable to patients.

I. In the presence of a tumour of the orbit repeated sarcoma-

³ *Ophtalm.*, U. K., IV., p. 38, 1884.

tons, even should we be enlightened by the histological examination, we must think of the infectious origin and not have recourse to any operation until previous treatment has proved negative.

2. Among the means of treatment we possess, we must include mercury, iodine, arsenic, and toxitherapy as it has been attempted with erysipelas or the pure cultures of streptococci by Feilchen,¹¹ Holst,¹² and Ealey.¹³ Lassar,¹⁴ Sprank,¹⁵ W. B. Johnson,¹⁶ Coley,¹⁷ and Repin¹⁸ have used by preference the streptococcal serum, which is less dangerous, and whose toxicity can be increased by the addition in the cultures of the micrococci prodigiousus. The injections are made into the tumour, at a remote point under the skin, or into the veins.

3. The research of the point of origin of the infection (nose, sinuses, pharynx) and the bacteriological determination of the toxins which are the cause, contribute to confirm the diagnosis and to lay down the basis for a rational medical treatment. It is only after this that we can have recourse to surgical interference, which is often powerless in the so-called sarcomas and lymphadenomas of the orbit.

The discussion was continued by

Dr. HENR. GARFITH (Manchester), who referred to a case of orbital sarcoma, accompanied by an unusual amount of inflammatory action, in which the growth closely enveloped the whole eyeball. He asked if anyone had thought it advisable in cases of exophthalmos, without other symptoms, to divide one or other rectus tendon, and explore the deeper parts of the orbit.

Professor FUCHS (Vienna) had observed a case of rhinoscleroma of both orbits, which had extended from the nasal cavity through the apex of the orbits. The most striking feature of the case was the early onset of immobility of the eyes.

Dr. ARCYLL ROBERTSON wished to support the view expressed by Professor Panas, that cases which presented every symptom of organic tumour of the orbit could still be cured by medical treatment.

Mr. NUTTSHAMPTON mentioned a case of single proptosis, with hypertrophy or semisolid oedema of the tissues in the corresponding temporal fossa, which had been perfectly stationary for the last five years.

Mr. SPENNER WATSON narrated a case in which double proptosis was cured after the removal of both inferior turbinal bones with other nasal growths.

Mr. ADAMS FROST spoke of a case of a patient who presented symmetrical tumours in both lachrymal glands, one of which was excised and found to be small round-celled sarcoma, the other recovered under iodide of potassium.

CASE OF ACUTE ORBITAL CALCULUS FOLLOWING A DENTAL ABSCESS.

Mrs. H. E. JONES and Mr. MORTON SMALE read notes of the case of a boy, aged 15, who was admitted to the hospital, having fallen from a van a few days before. He presented all the signs of acute orbital cellulitis. The eye was lost. The eyeball was everted, and free incisions made into the parts around, and much fluid pus escaped. The boy had complained of pain in the upper molar tooth; this was accordingly removed. An abscess at its root communicated with the antrum, and by an opening through the roof of the antrum into the orbit. After free drainage the boy recovered perfectly.

CARCINOMA OF THE BODY OF THE SPHENOID: COMPLETE EXCISION OF BOTH EYES.

Mrs. H. E. JONES and Mr. W. J. HARRIS read notes of a case of this description. The carcinoma was secondary to one of the breast, which had been removed two years before. The first sign of the orbital affection was sudden blindness of one eye, without intraocular changes; then followed proptosis,

exophthalmos, and impairment of vision, leading on to total ophthalmoplegia. The left eye followed the same course. The seat of origin of the growth found at the necropsy proved to be the body of the sphenoid.

A DISCUSSION ON THE QUESTION OF OPERATING IN CHRONIC GLAUCOMA.

Introduced by E. NATHANSON, F.R.C.S.,

Ophthalmic Surgeon St. Thomas's Hospital.

I THINK that it may be interesting both to ophthalmic surgeons and to those in other branches of practice to hear what practice the members of this Section follow in the treatment of chronic glaucoma; to hear whether experience is now more favourable to operation than it has been; whether there is an increasing tendency to leave cases of chronic glaucoma alone or to advise operative interference early.

In introducing the subject I have nothing new to propound; I desire simply to put before you for discussion a few of the many questions with which this difficult subject is beset.

There are many things about chronic glaucoma upon which we need spend no time to-day; we know that, speaking comprehensively, operations for chronic glaucoma are often negative in result and occasionally harmful; and we know that, even if nothing be done, the course of the disease is now and then so extremely slow (I mean ten years and upwards), that had an operation been performed early in the case, the operation could not have been credited with any share in the result. But such extremely slow cases are rare; and as chronic glaucoma when untreated commonly runs much the same course in both eyes of the same person, the effect of operation on one eye can often be gauged by the course the malady has already taken in the other.

1. I would ask first whether anything is gained by trying to distinguish between cases of chronic glaucoma in which the diagnosis admits of no doubt, and others, where, owing chiefly to the absence of decidedly increased tension, the diagnosis of a peculiar form of atrophy of the optic nerve with cupping of the disc is sometimes made? An optic atrophy, be it observed, occurring in the glaucomatous period of life, unaccompanied by true colour blindness, unaccompanied from beginning to end by the smallest indication of disease of the central nervous system, and lastly, limited by imperceptible gradations with typical chronic glaucoma. I myself believe that cases in which the disc shows well-marked glaucomatous cupping should almost without exception be looked upon and dealt with as glaucoma, whether demonstrable increase of tension and other common signs of glaucoma be present or not. I anticipate that in these, the simplest cases of "simple" glaucoma, the truly glaucomatous nature of the disease will sooner or later be established anatomically. Probably in these cases, the lamina cribrosa being very weak, yields to an increase of tension too slight to be detected by the finger. I am far from saying that the result of operating on such very quiet cases is as good as we could wish; but I venture to think that the habit of regarding them as something different from true glaucoma is undesirable, and may tend to induce in the surgeon an unduly hesitating attitude on the treatment of chronic glaucoma as a whole.

2. Another question: Is it true that iridectomy performed when the visual field is already lost nearly up to the centre is often followed quickly by a further loss of field which engulfs the centre and thus seriously damages visual acuity? And, if such rapid loss of field occurs after operation, is it more to be expected when the previous contraction was of the concentric type than when it took chiefly the form of a sector? My own experience on this point is favourable. I have had very few cases of quiet glaucoma in which the field became worse as an apparent result of the operation, whilst there is quite a number in which the field has remained the same after as before. The risk of such further rapid loss of field as a consequence of iridectomy is probably greater *ante* *op* than when the tension is much increased.

3. If we operate in chronic glaucoma, should the operation be done early, or, influenced by the fear of doing harm to a good eye, should we wait till the disease has made considerable progress, and there is but little to lose?

I am on the side of operating early and of operating first on the better eye if both are affected. Not only do we thus save more, but, and chiefly, the risk of displacement of the lens and internal hæmorrhage is certainly less in the early period, before marked atrophy of ciliary processes and iris has set in, and of course the hope of re-establishing the angle is better.

I cannot help thinking that the fear, to a large extent unfounded, of operating early, and the negative and sometimes harmful results of operating late are responsible for not a little of the general disbelief, or weak belief, in the benefit to be expected from operating for chronic glaucoma.

4. Another point: If we operate as early as possible in chronic glaucoma, we must, in practice, sometimes operate on cases in the prodromal stage before permanent loss of field and before much permanent change at the disc; cases, in short, some of which would, if left alone, become acute, others more or less quiet and chronic. There can hardly be a doubt that if iridectomy were commonly performed in the prodromal stage the number of persons who become blind of glaucoma would be considerably lessened. The risk of operation carefully done is very small; the prospects of immunity conferred by it very great.

The rule of operating in the prodromal stage must, of course, be applied with care; exceptions may be proper when a myotic is found to be efficient and the patient can be trusted to use it properly, and to report himself regularly. But I have a dread of letting such patients drift, as they are apt to do, into an acute outbreak or into permanent chronic glaucoma.

The rule for operating early in established simple glaucoma must also, of course, be relaxed at times, especially for the very old, and those who on other grounds are bad subjects. On the other hand, early operation is, I think, strongly called for in glaucoma occurring in young subjects, because, size of cornea and lens apart, juvenile glaucoma probably often indicates an early tendency to weakness of the suspensory ligament and of the blood vessels. For the same reason I am inclined to keep the incision further forward in young patients, especially when the anterior chamber is of full depth, than in older persons.

Some parts of the iris in cases of glaucoma are often atrophic, and the practice now, I believe, usually followed of selecting for removal the most healthy looking piece, will no doubt commend itself to all.

I have throughout spoken of "operation;" personally I almost invariably employ iridectomy as the first operation, reserving sclerotomy as a second operation in occasional cases, and making it then opposite to the iridectomy. I performed primary sclerotomy, by Wecker's method, many times some years ago, and gave it up. It will be instructive to hear other experiences of sclerotomy, whether performed by the subconjunctival method with a narrow knife, leaving a conjunctival and scleral bridge (de Wecker), or with a lance knife (Snellen and others).

I have as yet tried Priestley Smith's scleral puncture as a preliminary to iridectomy only twice, both times in acute glaucoma with very shallow chamber. I have nothing to say against the proceeding, and it certainly made the iridectomy easier.

Professor FUCHS (Vienna) had given up operation in cases of chronic glaucoma where there was no increase of tension. He always did iridectomy except when a fresh increase of tension came on after iridectomy when he did a sclerotomy.

Dr. MEYER (Paris) agreed with Mr. Nettleship's propositions generally with the exception of the first one. He had watched such cases for many years, and had seen the cupping of the disc becoming deeper and deeper without sufficient alteration of central or peripheral vision, and he did not regard them as cases of glaucoma. He always advised operation, whatever might be the diminution of vision or the state of the visual fields. He always performed iridectomy, having found after serious trial that all that sclerotomy does iridectomy does more surely.

Professor GAYET (Lyons) considered sclerotomy as an operation done rather for the satisfaction of the surgeon than in the interest of the patient. He performed iridectomy from choice, but where this was dangerous he preferred equatorial puncture of the eye.

Mr. CATCHETT felt that they ought to be very grateful to Mr. Nettleship for having brought this question forward at a time when they had the advantage of the presence of so many of their eminent foreign colleagues. In this disease it was essential to remember the well-known text, "That thou doest, do quickly;" and he was in favour of early operation. He laid great stress on the advantages of a cystoid cecatrix, and said that any ophthalmologist who could invent a certain method of securing this condition would deserve well of his country.

Mr. PRIESTLEY SMITH, referring to the question of diagnosis, said that a better agreement as to the sense in which the name "glaucoma" should be used was much wanted. To him, glaucoma meant a morbid process depending essentially on excess of pressure, while cases in which changes simulating those found in glaucoma arose from other causes than pressure, for example, physiological cupping supplemented by atrophy of the nerve, were not glaucoma at all. He thought, however, that a more general use of the tonometer would render those exceptional cases rarer than they are now supposed to be. The tonometer had rendered him good service for many years. He hoped that the new instrument shown by Dr. Koster would prove an advance on his own; its principle was certainly good, but he was not quite sure of its practical applicability at present.

His own experience in the operative treatment of chronic glaucoma appeared to him to justify the following conclusions:

1. It is right to operate at any stage of the disease so long as there is any sight worth saving, provided that the patient's general condition does not forbid an operation; and that he or his friends have been given clearly to understand that the operation is the only means, but not a certain means, of avoiding blindness.

2. The immediate safety of the eye as regards the operation depends chiefly on the avoidance of injury or displacement of the lens, and deep-seated hæmorrhage. The making of a scleral puncture so as to slacken the eye immediately before the iridectomy is a valuable safeguard against injury of the lens during operation and displacement of it afterwards. Scrupulous attention to the condition of the patient as regards sleep, bodily tranquillity, and the action of bowels and kidneys are the chief safeguards against deep-seated hæmorrhage, but in certain cases this complication is inevitable.

3. The ultimate success of the operation depends largely on the formation of a permanent subconjunctival fistula which keeps the eye slack. The presence of such a fistula is shown by a bleb-like elevation of the conjunctiva over some part of the cicatrix. Iridectomy for glaucoma will be a more perfect operation than it is at present when we have learned how to establish such a filtration scar in every case.

4. Permanent retention of vision is not always secured, however, even by an operation which fulfils the requirements already mentioned. The optic nerve, like other nerves, when once it has been reduced to a condition of partial atrophy, as in advanced glaucoma, is especially liable to undergo further atrophy when the nutrition of the nervous system in general fails. Anxiety, overwork, loss of appetite, and loss of sleep are potent causes of such failure. The treatment of glaucoma must therefore include, in addition to an efficient operation, careful and persistent attention to the health and habits of the patient.

Dr. LITTLE (Manchester) believed that iridectomy arrested the progress of chronic glaucoma in a considerable number of cases. He thought that a cystoid cecatrix was rather a desirable thing to have after operation. After a fair trial he had given up sclerotomy as a primary operation, but he thought sclerotomy should be done where iridectomy had failed; and he preferred to do it in the coloboma. He did not think that operation was the cause of further contraction of the fields. He thought iridectomy should be done in the very early stage of glaucoma, in fact, during the premonitory stage, as he was quite certain that in spite of myotics these cases did develop sooner or later into glaucoma.

The PRESIDENT (Mr. Henry Power) said the principle which had guided him had been whether the case was progressive

¹ See paper read at the Edinburgh Congress.

or not. Many cases depending on mental worry were purely temporary, and could be cured by general treatment with eserine. In regard to scleral puncture, he could say with some certainty that it was useless in chronic glaucoma.

Professor PAVAS said that the treatment of chronic glaucoma by myotics ranked foremost; no fewer than four applications should be made daily, experiments having shown that the action of myotics does not last more than five hours. He preferred an ointment of vaseline, salicylate of eserine, and hydrochlorate of pilocarpin. The irritation of the conjunctiva by eserine was thus avoided, and the application could be continued many months. Where myotics were insufficient he performed sclerotomy, and where this failed iridectomy.

Mr. SWANZ was in favour of early operation in chronic glaucoma; a certain amount of loss of sight was in many cases to be reckoned with, and for this reason he declined to operate in cases where the field was so contracted as to approach fixation point.

Mr. ADAMS FRASER, until recently, operated as routine practice in chronic glaucoma, but he had done so less often lately, owing to a suspicion that it did not arrest the disease. He had found preliminary scleral puncture useful in preventing failure of vision as a result of operation.

Mr. J. G. MACKINLAY said that it was not advisable to wait too long before operating in chronic glaucoma; it was necessary to make the incision very far back.

Mr. TREACHER COLLINS had examined many sections of eyes with cystoid cataracts, and had found that they were formed by a prolapse of a fold of iris into the sclero-corneal wound. This prevented the sclero-corneal tissue from reuniting, and when the conjunctiva healed on the surface a weak spot was left in the fibrous tissue of the globe, which yielded to the pressure of fluid within.

Mr. R. WILLIAMS (Liverpool) thought that sclerotomy was to be preferred to iridectomy, on account of its greater simplicity.

Mr. G. WALKER (Liverpool) expressed his belief that it was essential in the treatment of glaucoma to correct errors of refraction, especially hypermetropia. He had abandoned iridectomy for glaucoma more than twenty years ago. In order to form a cystoid catarix he dissected up a flap of conjunctiva, and tucked it into the wound of the incision into the anterior chamber; he had found this efficacious.

ON THE PATER NEGLECT OF THE EYESIGHT QUESTION IN BOARD OF TRADE INQUIRIES INTO SHIPPING DISASTERS.

By T. H. BICKERTON, M.R.C.S.,

Surgeon, Liverpool Royal Infirmary.

ALTHOUGH the public memory is notoriously short, it will hardly be forgotten that on February 1st last a deputation from the British Medical Association and the Ophthalmological Society waited upon Mr. Bryce, who then occupied the position of President of the Board of Trade, to urge the adoption of more precise tests for eyesight in the examination of the mercantile marine and railway employees.

It is no compliment to the gentlemen who formed that deputation, or to the carefully prepared case which they laid before the Board of Trade, that the visual test question is precisely in the same position as it was then. Possibly the President of that overburdened department of Government—the Board of Trade—thought that he was doing well by the deputation when he gave it courteous hearing, and that nothing further would result from his neglect to take action upon this important matter. In fact Mr. Bryce, in his reply to the unanswerable arguments brought to his notice, seemed to resent the mere suggestion that the Board of Trade had not pursued the most enlightened policy possible in dealing with the question of sailors' eyesight.

It may, perhaps, seem a little ungracious to criticise that reply at the present juncture; earlier action, however, on our part would have constituted a breach of the unwritten law of etiquette in such matters. It was promised us that the subject should receive careful consideration, and as the wheels of officialdom run proverbially slowly, a policy of passive wait-

ing in the hope that the result of this promised "consideration" would ultimately be vouchsafed was practically the only line of action open to us. Mr. Bryce, too, it should be remembered, merely voiced the opinion of the permanent officials of the Board of Trade, and it is against their policy of inertia that my criticisms are directed, rather than at the statesman who was then their head and mouthpiece.

Mr. Bryce asserted that his "department had shown due diligence in dealing with the matter." At this stage of the colour vision and eyesight question it is perhaps unnecessary to expose the baselessness of such a claim. It is well known that the "diligence" of the department to which is entrusted the safeguarding of the travelling community by land or sea has manifested itself, first in refusing to admit the danger of the colour-blind factor, and subsequently, when compelled by facts to abandon this untenable position, in stubbornly resisting any effort which sought to eliminate visually afflicted persons from serving on our railways or in our mercantile marine.

The action of the medical profession in persistently pointing out the dangers arising from visual defect and suggesting the adoption of remedial measures has been, until quite recent times regarded in the light of mere faddism and so long as discussions and recommendations were confined to the medical press the subject was a closed book to the public, and the Board of Trade treated the views of those competent to give an opinion with undisguised contempt. That the rights of the case were unknown to the public may be gathered from the fact that, though the dangers of employing colour-blind men as sailors were first pointed out in 1856, a leading daily paper stated in 1888 that "too much fuss is made about the supposed deficiency." For such a statement the public press may rightly plead ignorance, but no such plea can be put forward by the Board of Trade. They were well aware of the researches of Dr. Wilson (Edinburgh), whose work on *Colour Blindness*, published in 1855, will ever be a living monument to his labours; and they knew well of the efforts of Mr. James Hogg, to whose admirable exertions I believe we owe the first Parliamentary return on Colour Vision; of Mr. Rudenell Carter, of Cantor Lecture fame; of Dr. Bailey (London); and last, but not least, of Dr. Joy Jeffries, of Boston, U.S.A., whose work on *Colour Blindness* has done more than any other to point out to the English-speaking people the dangers and the means of detection of that condition. But to all advice the Board of Trade turned a deaf ear, and I believe it was not until I enlisted Dr. Farquharson's assistance to direct Parliamentary attention to the question that the public began to be awakened to a due sense of the needless peril to which our goods were subjected from visually afflicted sailors; and the Board of Trade to see that they had the public and not the medical profession only to deal with. For when once the vital importance of the matter was pointed out to the general and shipping press their voice has not ceased to make itself heard in the cause, and it has done incalculable good towards educating the nation to understand aright the risk which must ever accrue to lives and shipping property from colour-blind and defective-sighted officers and look-outs.

As far back as December, 1877, Dr. Caldwell, surgeon on board the historic Cunarder *Russia*, wrote to the *Nautical Magazine* as follows:

"1. I hold that the quality of eyesight that was good enough to steer clear of the old sailing packet is by no means adequate to recognise surely and promptly the lights of the modern steamer, where the time for reflection is often limited to seconds.

"2. That more collisions occur through mistaking coloured lights than almost all other causes combined."

The truth of the first statement, Dr. Caldwell goes on to remark, is almost self-evident, and will be conceded when one considers the increasing rate of speed as compared with the more leisurely progress of the days when steam was unknown. The history of accidents from collision, and the conflicting evidence with reference to the bearings of coloured lights, as exemplified in our law courts, will, I think, sustain the latter statement.

So wrote Dr. Caldwell some twenty years ago, and it speaks volumes for the "diligence" which the Board of Trade

has exercised over this subject that we, in the present year of grace, should still be urging the adoption of remedial measures to safeguard the public from dangers which were so pertinently indicated so far back as 1876.

Apparently the Board of Trade take credit to themselves concerning the Royal Society inquiry into the colour vision question. It is well known, however, that it was only after steady pressure, long continued, that such a step was practically forced upon the Board of Trade. The inquiry was a costly one, and its findings were quite in accord with the latest scientific teachings. But the Board of Trade, if we except their adoption of the Holmgren wool test, have done but little towards adopting the Royal Society's recommendations. Their action in thus seeking advice, and then failing to act upon it, is clearly evidential that the inquiry was wrong from them with the greatest reluctance. They were practically compelled by the influence of public opinion to order it, and their subsequent neglect of its suggestions lays the Board of Trade open to the very serious charge of regarding the Commission in the nature of a sop which the united forces of the medical profession and the press compelled them to throw to the Cerberus of public opinion.

The official position on the subject of colour blindness and its risks is the illogical one which assumes the absence of risk, because among the direct causes of collision, definite cases of the disaster being due to colour blindness or to defective eyesight do not largely figure.

"It was certainly very remarkable," said Mr. Bryce, "that an exceedingly small number of accidents, he might almost say few or no accidents, at sea or on land had been so far traceable to this cause. He had for some months past carefully perused the reports of the courts of inquiry, and he had made most careful inquiries of the heads of the railway and marine departments, and had been assured that in scarcely any case had it been suggested, or so far as they knew could it be suggested, that defects of vision had been the cause of accidents."
